Express the potential at the center of the square:

$$V = \frac{kq_1}{r} + \frac{kq_2}{r} + \frac{kq_3}{r} + \frac{kq_4}{r} = \frac{k}{r}(q_1 + q_2 + q_3 + q_4) = \frac{k}{r}\sum_{i=1}^{4} q_i$$

(*a*) If the charges are positive:

$$V = \frac{8.988\times10^{9}\ \mathrm{N\cdot m^2/C^2}}{2.00\sqrt{2}\ \mathrm{m}}(4)(2.00\,\mu\mathrm{C}) = \boxed{25.4\,\mathrm{kV}}$$

(*b*) If three of the charges are positive and one is negative:

$$V = \frac{8.988\times10^{9}\ \mathrm{N\cdot m^2/C^2}}{2.00\sqrt{2}\ \mathrm{m}}(2)(2.00\,\mu\mathrm{C}) = \boxed{12.7\,\mathrm{kV}}$$

(*c*) If two are positive and two are negative:

$$V = \boxed{0}$$

27 • **[SSM]** Three point charges are fixed at locations on the x-axis: q_1 is at $x = 0.00$ m, q_2 is at $x = 3.00$ m, and q_3 is at $x = 6.00$ m. Find the electric potential at the point on the y axis at $y = 3.00$ m if (a) $q_1 = q_2 = q_3 = +2.00\ \mu$C, ($b$) $q_1 = q_2 = +2.00\ \mu$C and $q_3 = -2.00\ \mu$C, and (c) $q_1 = q_3 = +2.00\ \mu$C and $q_2 = -2.00\ \mu$C. (Assume the potential is zero very far from all charges.)

Picture the Problem The potential at the point whose coordinates are (0, 3.00 m) is the algebraic sum of the potentials due to the charges at the three locations given.

Express the potential at the point whose coordinates are (0, 3.00 m):

$$V = k\sum_{i=1}^{3}\frac{q_i}{r_i} = k\left(\frac{q_1}{r_1}+\frac{q_2}{r_2}+\frac{q_3}{r_3}\right)$$

(a) For $q_1 = q_2 = q_3 = 2.00\ \mu$C:

$$V = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(2.00\ \mu\text{C})\left(\frac{1}{3.00\,\text{m}}+\frac{1}{3.00\sqrt{2}\,\text{m}}+\frac{1}{3.00\sqrt{5}\,\text{m}}\right)$$

$$= \boxed{12.9\,\text{kV}}$$

(b) For $q_1 = q_2 = 2.00\ \mu$C and $q_3 = -2.00\ \mu$C:

$$V = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(2.00\ \mu\text{C})\left(\frac{1}{3.00\,\text{m}}+\frac{1}{3.00\sqrt{2}\,\text{m}}-\frac{1}{3.00\sqrt{5}\,\text{m}}\right)$$

$$= \boxed{7.55\,\text{kV}}$$

(c) For $q_1 = q_3 = 2.00\ \mu$C and $q_2 = -2.00\ \mu$C:

$$V = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(2.00\ \mu\text{C})\left(\frac{1}{3.00\,\text{m}}-\frac{1}{3.00\sqrt{2}\,\text{m}}+\frac{1}{3.00\sqrt{5}\,\text{m}}\right)$$

$$= \boxed{4.43\,\text{kV}}$$

28 • Points A, B, and C are fixed at the vertices of an equilateral triangle whose edges are 3.00-m long. A point particle with a charge of +2.00 μC is fixed at each of vertices A and B. (a) What is the electric potential at point C? (Assume the potential is zero very far from all charges.) (b) How much work is required to move a point particle having a charge of +5.00 μC from a distance of infinity to point C? (c) How much additional work is required to move the +5.00-μC point particle from point C to the midpoint of side AB?

Picture the Problem (*a*) The potential at vertex *C* is the algebraic sum of the potentials due to the point charges at vertices *A* and *B*. (*b*) The work required to bring a charge from infinity to vertex *C* equals the change in potential energy of the system during this process. (*c*) The additional work required to move the +5.00-μC point particle from point *C* to the midpoint of side *AB* is the product of +5.00-μC and the difference in potential between point *C* and the midpoint of side *AB*.

(*a*) Express the potential at vertex *C* as the sum of the potentials due to the point charges at vertices *A* and *B*:

$$V_C = k\left(\frac{q_A}{r_A} + \frac{q_B}{r_B}\right)$$

Because $q_A = q_B = q_2$:

$$V_C = kq_2\left(\frac{1}{r_A} + \frac{1}{r_B}\right)$$

Substitute numerical values and evaluate V_C:

$$V_C = \left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(2.00\,\mu\text{C}\right)\left(\frac{1}{3.00\,\text{m}} + \frac{1}{3.00\,\text{m}}\right)$$
$$= 11.98\,\text{kV} = \boxed{12.0\,\text{kV}}$$

(*b*) Express the required work in terms of the change in the potential energy of the system:

$$W_{\infty\to C} = \Delta U = U_C - U_\infty = U_C$$

Substituting for U_C yields:

$$W_{\infty\to C} = q_5 V_C$$

Substitute numerical values and evaluate $W_{\infty\to C}$:

$$W_{\infty\to C} = \left(5.00\,\mu\text{C}\right)\left(11.98\,\text{kV}\right) = \boxed{59.9\,\text{mJ}}$$

(*c*) Express the required work in terms of the change in the potential energy of the system:

$$W_{C\to\text{midpoint}} = \Delta U = U_{\substack{\text{midpoint}\\ \text{of } AB}} - U_C$$

Substituting for $U_{\substack{\text{midpoint}\\ \text{of } AB}}$ and U_C yields:

$$W_{C\to\text{midpoint}} = q_5 V_{\substack{\text{midpoint}\\ \text{of } AB}} - q_5 V_C = q_5\left(V_{\substack{\text{midpoint}\\ \text{of } AB}} - V_C\right) \qquad (1)$$

The potential at the midpoint of *AB* is the sum of the potentials due to the point charges at vertices *A* and *B*:

$$V_{\substack{\text{midpoint}\\ \text{of } AB}} = k\left(\frac{q_A}{r_A} + \frac{q_B}{r_B}\right)$$

Because $q_A = q_B = q_2$ and $r_A = r_B = r$:

$$V_{\substack{\text{midpoint}\\ \text{of } AB}} = \frac{2kq_2}{r}$$

where r is the distance from vertex *A* (and vertex *B*) to the midpoint of side *AB* of the triangle.

Substituting in equation (1) and simplifying yields:

$$W_{C\to\text{midpoint}} = q_5\left(\frac{2kq_2}{r} - V_C\right)$$

Substitute numerical values and evaluate $W_{C\to\text{midpoint}}$:

$$W_{C\to\text{midpoint}} = (+5.00\ \mu\text{C})\left(\frac{2(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)(+2.00\ \mu\text{C})}{1.50\ \text{m}} - 11.98\ \text{kV}\right)$$

$$= \boxed{59.9\ \text{mJ}}$$

29 •• Three identical point particles with charge q are at the vertices of an equilateral triangle that is circumscribed by a circle of radius a that lies in the $z = 0$ plane and is centered at the origin. The values of q and a are $+3.00\ \mu$C and 60.0 cm, respectively. (Assume the potential is zero very far from all charges.) (*a*) What is the electric potential at the origin? (*b*) What is the electric potential at the point on the z axis at $z = a$? (*c*) How would your answers to Parts (*a*) and (*b*) change if the charges were still on the circle but one is no longer at a vertex of the triangle? Explain your answer.

Picture the Problem The electric potential at the origin and at $z = a$ is the algebraic sum of the potentials at those points due to the individual charges distributed along the equator.

(*a*) Express the potential at the origin as the sum of the potentials due to the charges placed at 120° intervals along the equator of the sphere:

$$V_{\text{origin}} = k\sum_{i=1}^{3}\frac{q_i}{r_i} = 3\frac{kq}{a}$$

Substitute numerical values and evaluate V_{origin}:

$$V_{\text{origin}} = \frac{3\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.00\ \mu\text{C}\right)}{0.600\,\text{m}} = \boxed{135\,\text{kV}}$$

(*b*) Using geometry, find the distance from each charge to $z = a$:

$$a = 0.600\sqrt{2}\,\text{m}$$

Proceed as in (*a*) with $a = 0.600\sqrt{2}\,\text{m}$:

$$V = k\sum_{i=1}^{3}\frac{q_i}{r_i'} = 3\frac{kq}{a'}$$

$$= \frac{3\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\left(3.00\ \mu\text{C}\right)}{0.600\sqrt{2}\,\text{m}}$$

$$= \boxed{95.3\,\text{kV}}$$

(*c*) Because the two field points are equidistant from all points on the circle, the answers for Parts (*a*) and (*b*) would not change.

30 •• Two point charges q and q' are separated by a distance a. At a point $a/3$ from q and along the line joining the two charges the potential is zero. (Assume the potential is zero very far from all charges.) (*a*) Which of the following statements is true?

(1) The charges have the same sign.
(2) The charges have opposite signs.
(3) The relative signs of the charges can not be determined by using data given.

(*b*) Which of the following statements is true?

(1) $|q| > |q'|$.
(2) $|q| < |q'|$.
(3) $|q| = |q'|$.
(4) The relative magnitudes of the charges cannot be determined by using the data given.

(*c*) Find the ratio q/q'.

Picture the Problem We can use the fact that the electric potential at the point of interest is the algebraic sum of the potentials at that point due to the charges q and q' to find the ratio q/q'.

(a) The only way that, in the absence of other point charges, the potential can be zero at $a/3$ is if q and q' have opposite signs. $\boxed{2}$ is correct.

(b) Because the point of interest is closer to q, the magnitude of q must be less than the magnitude of q'. $\boxed{2}$ is correct.

(c) Express the potential at the point of interest as the sum of the potentials due to the two charges:

$$\frac{kq}{\frac{1}{3}a}+\frac{kq'}{\frac{2}{3}a}=0$$

Simplify to obtain:

$$q+\frac{q'}{2}=0 \Rightarrow \frac{q}{q'}=\boxed{-\frac{1}{2}}$$

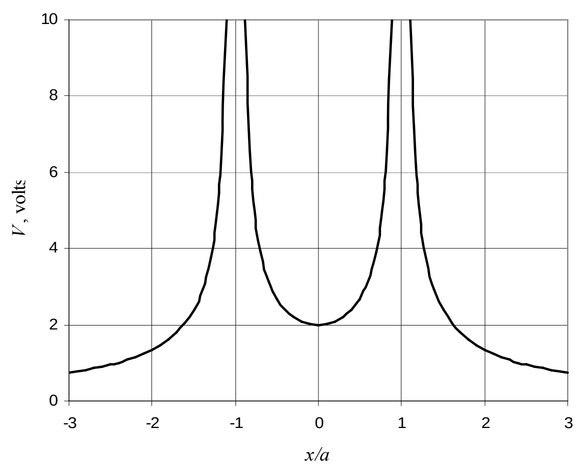
31 •• [SSM] Two identical positively charged point particles are fixed on the x-axis at $x = +a$ and $x = -a$. (a) Write an expression for the electric potential $V(x)$ as a function of x for all points on the x-axis. (b) Sketch $V(x)$ versus x for all points on the x axis.

Picture the Problem For the two charges, $r = |x-a|$ and $|x+a|$ respectively and the electric potential at x is the algebraic sum of the potentials at that point due to the charges at $x = +a$ and $x = -a$.

(a) Express $V(x)$ as the sum of the potentials due to the charges at $x = +a$ and $x = -a$:

$$V=\boxed{kq\left(\frac{1}{|x-a|}+\frac{1}{|x+a|}\right)}$$

(b) The following graph of V as a function of x/a was plotted using a spreadsheet program:



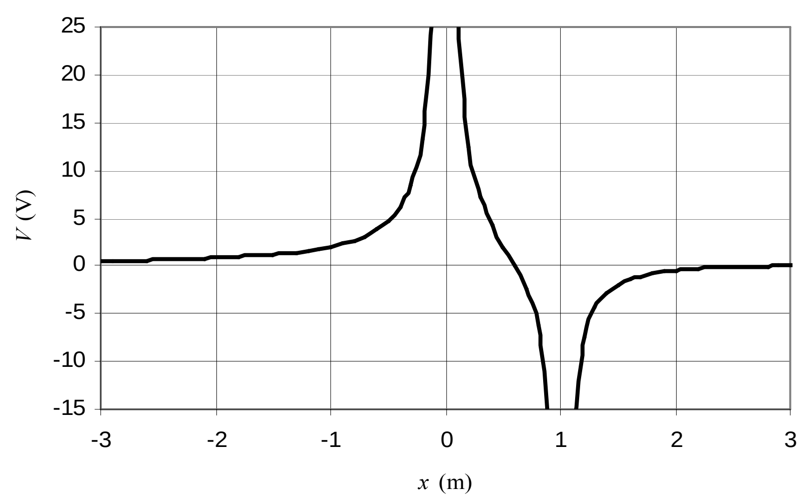
32 •• A point charge of $+3e$ is at the origin and a second point charge of $-2e$ is on the x-axis at $x = a$. (*a*) Sketch the potential function $V(x)$ versus x for all points on the x axis. (*b*) At what point or points, if any, is $V=$ zero on the x axis? (*c*) What point or points, if any, on the x-axis is the electric field zero? Are these locations the same locations found in Part (*b*)? Explain your answer. (*d*) How much work is needed to bring a third charge $+e$ to the point $x = \frac{1}{2}a$ on the x-axis?

Picture the Problem For the two charges, $r = |x-a|$ and $|x|$ respectively and the electric potential at x is the algebraic sum of the potentials at that point due to the charges at $x = a$ and $x = 0$. We can use the graph and the function found in Part (*a*) to identify the points at which $V(x) = 0$. We can find the work needed to bring a third charge $+e$ to the point $x = \frac{1}{2}a$ on the x axis from the change in the potential energy of this third charge.

(*a*) The potential at x is the sum of the potentials due to the point charges $+3e$ and $-2e$:

$$V(x) = \frac{k(3e)}{|x|} + \frac{k(-2e)}{|x-a|}$$

The following graph of $V(x)$ for $ke = 1$ and $a = 1$ was plotted using a spreadsheet program.



(*b*) From the graph we can see that $V(x) = 0$ when:

$$x = \boxed{\pm\infty}$$

Examining the function, we see that $V(x)$ is also zero provided:

$$\frac{3}{|x|} - \frac{2}{|x-a|} = 0$$

For $x > 0$, $V(x) = 0$ when:

$$x = \boxed{3a}$$

For $0 < x < a$, $V(x) = 0$ when:

$$x = \boxed{0.6a}$$

(*c*) The electric field at x is the sum of the electric fields due to the point charges $+3e$ and $-2e$:

$$E(x) = \frac{k(3e)}{x^2} + \frac{k(-2e)}{(x-r)^2}$$

Setting $E(x) = 0$ and simplifying yields:

$$x^2 - 6ax + 3a^2 = 0$$

Solve this equation to find the points on the x-axis where the electric field is zero:

$$x = \boxed{5.4a} \text{ and } x = \boxed{0.55a}$$

Note that the zeros of the electric field are different from the zeros of the electric potential. This is generally the case although, in special cases, they can be the same.

(*d*) Express the work that must be done in terms of the change in potential energy of the charge:

$$W = \Delta U = qV\left(\tfrac{1}{2}a\right)$$

Evaluate the potential at $x = \frac{1}{2}a$:

$$V\left(\tfrac{1}{2}a\right) = \frac{k(3e)}{\left|\frac{1}{2}a\right|} + \frac{k(-2e)}{\left|\frac{1}{2}a - a\right|} = \frac{6ke}{a} - \frac{4ke}{a} = \frac{2ke}{a}$$

Substitute for $V\left(\frac{1}{2}a\right)$ and q to obtain:

$$W = e\left(\frac{2ke}{a}\right) = \boxed{\frac{2ke^2}{a}}$$

33 ••• **[SSM]** A dipole consists of equal but opposite point charges $+q$ and $-q$. It is located so that its center is at the origin, and its axis is aligned with the y-axis (Figure 23-32) The distance between the charges is L. Let $\vec{r}$ be the vector from the origin to an arbitrary field point and θ be the angle that $\vec{r}$ makes with the $+y$ direction. (*a*) Show that at large distances from the dipole (that is for $r >> L$), the dipole's electric potential is given by $V(r,\theta) \approx k\vec{p}\cdot\hat{r}/r^2 = kp\cos\theta/r^2$, where $\vec{p}$ is the dipole moment of the dipole and θ is the angle between $\vec{r}$ and $\vec{p}$. (*b*) At what points in the region $r >> L$, other than at infinity, is the electric potential zero?

Picture the Problem The potential at the arbitrary field point is the sum of the potentials due to the equal but opposite point charges.

(*a*) Express the potential at the arbitrary field point at a large distance from the dipole:

$$V = V_+ + V_- = \frac{kq}{r_+} + \frac{k(-q)}{r_-} = kq\left(\frac{1}{r_+} - \frac{1}{r_-}\right) = kq\left(\frac{r_- - r_+}{r_+ r_-}\right)$$

Referring to the figure, note that, for the far field ($r >> L$):

$$r_- - r_+ \approx L\cos\theta \text{ and } r_+ \approx r_- \approx r$$

Substituting and simplifying yields:

$$V(r,\theta) = kq\left(\frac{L\cos\theta}{r^2}\right) = \frac{kqL\cos\theta}{r^2}$$

or, because $p = qL$,

$$V(r,\theta) = \frac{kp\cos\theta}{r^2}$$

Finally, because $\vec{\boldsymbol{p}} \cdot \hat{\boldsymbol{r}} = p\cos\theta$:

$$V(r,\theta) = \boxed{\frac{k\vec{\boldsymbol{p}} \cdot \hat{\boldsymbol{r}}}{r^2}}$$

(*b*) $V(r,\theta) = 0$ where $\cos\theta = 0$:

$\theta = \cos^{-1} 0 = 90° \Rightarrow V = 0$ at points on the *z* axis. Note that these locations are equidistant from the two oppositely-charged ends of the dipole.

34 ••• A charge configuration consists of three point charges located on the *z* axis (Figure 23-33). One has a charge equal to $-2q$, and is located at the origin. The other two each have a charge equal to $+q$, one is located at $z = +L$ and the other is located at $z = -L$. This charge configuration can be modeled as two dipoles: one centered at $z = +L/2$ and with a dipole moment in the $+z$ direction, the other centered at $z = -L/2$ and with a dipole moment in the $-z$ direction. Each of these dipoles has a dipole moment that has a magnitude equal to qL. Two dipoles arranged in this fashion form a *linear electric quadrupole*. (There are other geometrical arrangements of dipoles that create quadrupoles but they are not linear.) (*a*) Using the result from Problem 33, show that at large distances from the quadrupole (that is for $r >> L$), the electric potential is given by $V_{\text{quad}}(r,\theta) = 2kB\cos^2\theta/r^3$, where $B = qL^2$. (*B* is the magnitude of the quadrupole moment of the charge configuration.) (*b*) Show that on the positive *z* axis, this potential gives an electric field (for $z >> L$) of $\vec{\boldsymbol{E}} = (6kB/z^4)\hat{\boldsymbol{k}}$. (*c*) Show that you get the result of Part (*b*) by adding the electric fields from the three point charges.

Picture the Problem (*a*) The electric potential due to the linear electric quadrupole is the sum of the potentials of the two dipoles. (*b*) The electric field on the *y* axis can be obtained from the electric potential on the *y* axis using $\vec{E}_{z\text{ axis}} = -\frac{\partial V_{z\text{ axis}}}{\partial z}\hat{k}$.

(*a*) The electric potential due to the linear electric quadrupole is given by:

$$V_{\text{quad}} = V_{\uparrow} + V_{\downarrow}$$

From Problem 23-33:

$$V_{\uparrow} = \frac{kqL\cos\theta}{r_{\uparrow}^2} \text{ and } V_{\downarrow} = -\frac{kqL\cos\theta}{r_{\downarrow}^2}$$

Substituting for $V_{\uparrow}$ and $V_{\downarrow}$ yields:

$$V_{\text{quad}} = \frac{kqL\cos\theta}{r_{\uparrow}^2} - \frac{kqL\cos\theta}{r_{\downarrow}^2}$$

Simplify to obtain:

$$V_{\text{quad}} = kqL\cos\theta\left(\frac{r_{\downarrow}^2 - r_{\uparrow}^2}{r_{\uparrow}^2 r_{\downarrow}^2}\right) = kqL\cos\theta\left(\frac{(r_{\downarrow} - r_{\uparrow})(r_{\downarrow} + r_{\uparrow})}{r_{\uparrow}^2 r_{\downarrow}^2}\right)$$

Referring to the figure, note that, for the far field ($r >> L$):

$r_{\downarrow} - r_{\uparrow} \approx L\cos\theta$, $r_{\uparrow} + r_{\downarrow} \approx 2r$, and $r_{\uparrow} \approx r_{\downarrow} \approx 2r$

Substitute and simplify to obtain:

$$V_{\text{quad}}(r,\theta) \approx kqL\cos\theta\left(\frac{2rL\cos\theta}{r^4}\right) = \frac{2kqL^2\cos^2\theta}{r^3}$$

Because $B = qL^2$:

$$V_{\text{quad}}(r,\theta) \approx \boxed{\frac{2kB\cos^2\theta}{r^3}}$$

(*b*) The electric field on the *z* axis is related to the electric potential on the *z* axis:

$$\vec{E}_{z\text{ axis}} = -\frac{\partial V_{z\text{ axis}}}{\partial z}\hat{k}$$

On the *y* axis, $\theta = 0$ and $\cos\boldsymbol{\theta} = 1$. Hence:

$$V_{y\text{ axis}} \approx \frac{2kB}{y^3}$$

Substituting for $V_{z\text{ axis}}$ yields:

$$\vec{E}_{z\text{ axis}} = -\frac{\partial}{\partial z}\left(\frac{2kB}{z^3}\right)\hat{k} = \boxed{\frac{6kB}{z^4}\hat{k}}$$

(*c*) The *E* field on the *z* axis is given by:

$$\vec{E}_{z\text{ axis}} = kq\left(\frac{1}{(z-L)^2} - \frac{2}{z^2} + \frac{1}{(z+L)^2}\right)\hat{k}$$

Letting $w = L^2/z^2$ yields:

$$\vec{E}_{z\text{ axis}} = \frac{kq}{z^2}\left(\frac{1}{(1-w)^2} - 2 + \frac{1}{(1+w)^2}\right)\hat{k}$$

Expand $(1-w)^{-2}$ and $(1+w)^{-2}$ binomially to obtain:

$$(1-w)^{-2} = 1 + 2w + 3w^2 + \text{higher-order terms}$$

and

$$(1+w)^{-2} = 1 - 2w + 3w^2 + \text{higher-order terms}$$

For $w << 1$:

$$(1-w)^{-2} \approx 1 + 2w + 3w^2$$

and

$$(1+w)^{-2} \approx 1 - 2w + 3w^2$$

Substituting in the expression for $\vec{E}_{z\text{ axis}}$ and simplifying yields:

$$\vec{E}_{z\text{ axis}} \approx \frac{kq}{z^2}\left(1 + 2w + 3w^2 - 2 + 1 - 2w + 3w^2\right)\hat{k} = \frac{kq}{z^2}\left(6w^2\right)\hat{k}$$

Finally, substitute for *w* to obtain:

$$\vec{E}_{z\text{ axis}} \approx \frac{kq}{z^2}\left(\frac{6L^2}{z^2}\right)\hat{k} = \frac{6kqL^2}{z^4}\hat{k}$$

$$= \boxed{\frac{6kB}{z^4}\hat{k}}$$

Computing the Electric Field from the Potential

35 • A uniform electric field is in the $-x$ direction. Points *a* and *b* are on the *x*-axis, with *a* at $x = 2.00$ m and *b* at $x = 6.00$ m. (*a*) Is the potential difference $V_b - V_a$ positive or negative? (*b*) If $|V_b - V_a|$ is 100 kV, what is the magnitude of the electric field?

Picture the Problem We can use the relationship $E_x = -(dV/dx)$ to decide the sign of $V_b - V_a$ and $E = \Delta V/\Delta x$ to find *E*.

(*a*) Because $E_x = -(dV/dx)$, V is greater for larger values of x. So:

$$\boxed{V_b - V_a \text{ is positive.}}$$

(*b*) Express E in terms of $V_b - V_a$ and the separation of points a and b:

$$E_x = \frac{\Delta V}{\Delta x} = \frac{V_b - V_a}{\Delta x}$$

Substitute numerical values and evaluate E_x:

$$E_x = \frac{100\,\text{kV}}{6.00\,\text{m} - 2.00\,\text{m}} = \boxed{25.0\ \text{kV/m}}$$

36 • An electric field is given by the expression $\vec{E} = bx^3\hat{i}$, where $b = 2.00\ \text{kV/m}^4$. Find the potential difference between the point at $x = 1.00$ m and the point at $x = 2.00$ m. Which of these points is at the higher potential?

Picture the Problem Because $V(x)$ and E_x are related through $E_x = -\,dV/dx$, we can find V from E by integration.

Separate variables in $E_x = -\,dV/dx$ and substitute for b to obtain:

$$dV = -E_x dx = -\left(2.00x^3\,\frac{\text{kV}}{\text{m}^4}\right)dx$$

Integrate V from V_1 to V_2 and x from $x = 1.00$ m to $x = 2.00$ m:

$$\int_{V_1}^{V_2} dV = V_2 - V_1$$
$$= -\left(2.00\,\frac{\text{kV}}{\text{m}^4}\right)\int_{1.00\,\text{m}}^{2.00\,\text{m}} x^3 dx$$
$$= -\left(2.00\,\frac{\text{kV}}{\text{m}^4}\right)\left[\tfrac{1}{4}x^4\right]_{1.00\,\text{m}}^{2.00\,\text{m}}$$

Simplify to obtain:

$$V_2 - V_1 = \boxed{-7.50\,\text{kV}}$$

Because $V_2 = V_1 + 7.50\,\text{kV}$, the point at $x = 2.00$ m is at the higher potential.

37 •• The electric field on the x axis due to a point charge fixed at the origin is given by $\vec{E} = \left(b/x^2\right)\hat{i}$, where $b = 6.00$ kV·m and $x \neq 0$. (*a*) Find the magnitude and sign of the point charge. (*b*) Find the potential difference between the points on the x-axis at $x = 1.00$ m and $x = 2.00$ m. Which of these points is at the higher potential.

Picture the Problem We can integrate $E_x = -dV_x/dx$ to obtain $V(x)$ and then use this function to find the electric potential difference between the given points.

(*a*) We know that this field is due to a point charge because it varies inversely with the square of the distance from the point charge. Because $\vec{E}_x$ is positive, the sign of the charge must be positive.

Because the given electric field is that due to a point charge, it follows that:

$$kq = 6.00\,\frac{\text{kV}}{\text{m}} \Rightarrow q = \frac{6.00\,\frac{\text{kV}}{\text{m}}}{k}$$

Substitute the numerical value of k and evaluate q:

$$q = \frac{6.00\,\frac{\text{kV}}{\text{m}}}{8.988\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}} = \boxed{668\,\text{nC}}$$

(*b*) The potential difference between the points on the x-axis at $x = 1.00$ m and $x = 2.00$ m is given by:

$$\Delta V = V_1 - V_2 \qquad (1)$$

From $E_x = -\dfrac{dV_x}{dx}$ we have:

$$\int_\infty^x dV = -\int_\infty^x E_x dx = -kq\int_\infty^x x^{-2}dx$$

or

$$V(x) - V(\infty) = \frac{kq}{x}$$

Letting $V(\infty) = 0$ yields:

$$V(x) = \frac{kq}{x} = \frac{6.00\,\text{kV}\cdot\text{m}}{x}$$

Substituting in equation (1) yields:

$$V_1 - V_2 = \frac{6.00\,\text{kV}\cdot\text{m}}{1.00\,\text{m}} - \frac{6.00\,\text{kV}\cdot\text{m}}{2.00\,\text{m}} = \boxed{3.00\,\text{kV}}$$

Because $V_1 = V_2 + 3.00\,\text{kV}$, the point at $x = 2.00$ m is at the higher potential.

38 •• The electric potential due to a particular charge distribution is measured at many points along the x-axis. A plot of this data is shown in Figure 23-34. At what location (or locations) is the x component of the electric field equal to zero? At this location (or these locations) is the potential also equal to zero? Explain your answer.

Picture the Problem Because $E_x = -dV/dx$, we can find the point(s) at which $E_x = 0$ by identifying the values for x for which $dV/dx = 0$.

Examination of the graph indicates that $dV/dx = 0$ at approximately 4.5 m. Thus $E_x = 0$ at $x \approx \boxed{4.5\,\text{m}}$. At this location, the potential is not zero. The electric field is zero when the slope of the potential function is zero.

39 •• Three identical point charges, each with a charge equal to q, lie in the xy plane. Two of the charges are on the y-axis at $y = -a$ and $y = +a$, and the third charge is on the x-axis at $x = a$. (*a*) Find the potential as a function of position along the x axis. (*b*) Use the Part (*a*) result to obtain an expression for $E_x(x)$, the x component of the electric field as a function of x, on. Check your answers to Parts (*a*) and (*b*) at the origin and as x approaches ∞ to see if they yield the expected results.

Picture the Problem Let r_1 be the distance from $(0, a)$ to $(x, 0)$, r_2 the distance from $(0, -a)$, and r_3 the distance from $(a, 0)$ to $(x, 0)$. We can express $V(x)$ as the sum of the potentials due to the charges at $(0, a)$, $(0, -a)$, and $(a, 0)$ and then find E_x from $-dV/dx$.

(*a*) Express $V(x)$ as the sum of the potentials due to the charges at $(0, a)$, $(0, -a)$, and $(a, 0)$:

$$V(x) = \frac{kq_1}{r_1} + \frac{kq_2}{r_2} + \frac{kq_3}{r_3}$$

where $q_1 = q_2 = q_3 = q$

At $x = 0$, the fields due to q_1 and q_2 cancel, so $E_x(0) = -kq/a^2$; this is also obtained from (*b*) if $x = 0$.

As $x\to\infty$, i.e., for $x >> a$, the three charges appear as a point charge $3q$, so $E_x = 3kq/x^2$; this is also the result one obtains from (*b*) for $x >> a$.

Substitute for the r_i to obtain:

$$V(x) = kq\left(\frac{1}{\sqrt{x^2+a^2}} + \frac{1}{\sqrt{x^2+a^2}} + \frac{1}{|x-a|}\right) = \boxed{kq\left(\frac{2}{\sqrt{x^2+a^2}} + \frac{1}{|x-a|}\right) \quad x \neq a}$$

(*b*) For $x > a$, $x - a > 0$ and:

$$|x-a| = x - a$$

Use $E_x = -dV/dx$ to find E_x:

$$E_x(x) = -\frac{d}{dx}\left[kq\left(\frac{2}{\sqrt{x^2+a^2}} + \frac{1}{x-a}\right)\right] = \boxed{\frac{2kqx}{\left(x^2+a^2\right)^{3/2}} + \frac{kq}{(x-a)^2} \quad x > a}$$

For $x < a$, $x - a < 0$ and:

$$|x-a| = -(x-a) = a - x$$

Use $E_x = -dV/dx$ to find E_x:

$$E_x(x) = -\frac{d}{dx}\left[kq\left(\frac{2}{\sqrt{x^2+a^2}} + \frac{1}{a-x}\right)\right] = \boxed{\frac{2kqx}{\left(x^2+a^2\right)^{3/2}} - \frac{kq}{(a-x)^2} \quad x < a}$$

Calculations of *V* for Continuous Charge Distributions

40 • A charge of +10.0 μC is uniformly distributed on a thin spherical shell of radius 12.0 cm. (Assume the potential is zero very far from all charges.) (*a*) What is the magnitude of the electric field just outside and just inside the shell? (*b*) What is the magnitude of the electric potential just outside and just inside the shell? (*c*) What is the electric potential at the center of the shell? (*d*) What is the magnitude of the electric field at the center of the shell?

Picture the Problem We can construct Gaussian surfaces just inside and just outside the spherical shell and apply Gauss's law to find the electric field at these locations. We can use the expressions for the electric potential inside and outside a spherical shell to find the potential at these locations.

(*a*) Apply Gauss's law to a spherical Gaussian surface of radius $r < 12.0$ cm:

$$\oint_S \vec{E}\cdot d\vec{A} = \frac{Q_{\text{enclosed}}}{\epsilon_0} = 0$$

because the charge resides on the outer surface of the spherical surface. Hence $\vec{E}_{r<12.0\,\text{cm}} = \boxed{0}$

Apply Gauss's law to a spherical Gaussian surface of radius $r > 12.0$ cm:

$$E\left(4\pi r^2\right) = \frac{q}{\epsilon_0}$$

and

$$E_{r>12.0\,\text{cm}} = \frac{q}{4\pi r^2 \epsilon_0} = \frac{kq}{r^2}$$

Substitute numerical values and evaluate $E_{r>12.0\,\text{cm}}$:

$$E_{r>12.0\,\text{cm}} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(10.0\,\mu\text{C})}{(0.120\,\text{m})^2} = \boxed{6.24\,\text{MV/m}}$$

(*b*) Express and evaluate the potential just inside the spherical shell:

$$V(r \le R) = \frac{kq}{R} = \frac{\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(10.0\,\mu\text{C})}{0.120\,\text{m}} = \boxed{749\,\text{kV}}$$

Express and evaluate the potential just outside the spherical shell:

$$V(r \geq R) = \frac{kq}{r} = \frac{\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(10.0\ \mu\text{C})}{0.120\ \text{m}} = \boxed{749\ \text{kV}}$$

(*c*) The electric potential inside a uniformly charged spherical shell is constant and given by:

$$V(r \leq R) = \frac{kq}{R} = \frac{\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(10.0\ \mu\text{C})}{0.120\ \text{m}} = \boxed{749\ \text{kV}}$$

(*d*) In Part (*a*) we showed that: $\vec{E}_{r<12.0\,\text{cm}} = \boxed{0}$

41 • [SSM] An infinite line charge of linear charge density +1.50 μC/m lies on the *z*-axis. Find the electric potential at distances from the line charge of (*a*) 2.00 m, (*b*) 4.00 m, and (*c*) 12.0 m. Assume that we choose $V = 0$ at a distance of 2.50 m from the line of charge.

Picture the Problem We can use the expression for the potential due to a line charge $V(r) = -2k\lambda \ln\left(\frac{r}{a}\right)$, where $V = 0$ at some distance $r = a$, to find the potential at these distances from the line.

Express the potential due to a line charge as a function of the distance from the line:

$$V(r) = -2k\lambda \ln\left(\frac{r}{a}\right)$$

Because $V = 0$ at $r = 2.50$ m:

$$0 = -2k\lambda \ln\left(\frac{2.50\ \text{m}}{a}\right)$$

Equivalently:

$$0 = \ln\left(\frac{2.50\ \text{m}}{a}\right) \Rightarrow \frac{2.50\ \text{m}}{a} = \ln^{-1}(0) = 1$$

Solving for *a* gives:

$$a = 2.50\ \text{m}$$

Thus we have a = 2.50 m and:

$$V(r) = -2\left(8.988\times10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.5\frac{\mu\text{C}}{\text{m}}\right)\ln\left(\frac{r}{2.50\,\text{m}}\right)$$
$$= -\left(2.696\times10^{4}\ \text{N}\cdot\text{m/C}\right)\ln\left(\frac{r}{2.50\,\text{m}}\right)$$

(a) Evaluate V(2.00 m):

$$V(2.00\,\text{m}) = -\left(2.696\times10^{4}\ \frac{\text{N}\cdot\text{m}}{\text{C}}\right)\ln\left(\frac{2.00\,\text{m}}{2.50\,\text{m}}\right) = \boxed{6.02\,\text{kV}}$$

(b) Evaluate V(4.00 m):

$$V(4.00\,\text{m}) = -\left(2.696\times10^{4}\ \frac{\text{N}\cdot\text{m}}{\text{C}}\right)\ln\left(\frac{4.00\,\text{m}}{2.50\,\text{m}}\right) = \boxed{-12.7\,\text{kV}}$$

(c) Evaluate V(12.0 m):

$$V(12.0\,\text{m}) = -\left(2.696\times10^{4}\ \frac{\text{N}\cdot\text{m}}{\text{C}}\right)\ln\left(\frac{12.0\,\text{m}}{2.50\,\text{m}}\right) = \boxed{-42.3\,\text{kV}}$$

42 • (a) Find the maximum net charge that can be placed on a spherical conductor of radius 16 cm before dielectric breakdown of the air occurs. (b) What is the electric potential of the sphere when it has this maximum charge? (Assume the potential is zero very far from all charges.)

Picture the Problem We can relate the dielectric strength of air (about 3.0 MV/m) to the maximum net charge that can be placed on a spherical conductor using the expression for the electric field at its surface. We can find the potential of the sphere when it carries its maximum charge using $V = kQ_{\text{max}}/R$.

(a) Express the dielectric strength of a spherical conductor in terms of the charge on the sphere:

$$E_{\text{breakdown}} = \frac{kQ_{\text{max}}}{R^2} \Rightarrow Q_{\text{max}} = \frac{E_{\text{breakdown}}R^2}{k}$$

Substitute numerical values and evaluate Q_{max}:

$$Q_{max} = \frac{(3.0\,\text{MV/m})(0.16\,\text{m})^2}{8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}} = 8.545\,\mu\text{C}$$

$$\approx \boxed{8.5\,\mu\text{C}}$$

(*b*) Because the charge carried by the sphere could be either positive or negative:

$$V_{max} = \pm\frac{kQ_{max}}{R}$$

$$= \pm\frac{\left(8.988\times10^9\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(8.545\,\mu\text{C})}{0.16\,\text{m}}$$

$$\approx \boxed{\pm4.8\times10^5\text{ V}}$$

43 • Find the maximum surface charge density σ_{max} that can exist on the surface of any conductor before dielectric breakdown of the air occurs.

Picture the Problem We can solve the equation giving the electric field at the surface of a conductor for the greatest surface charge density that can exist before dielectric breakdown of the air occurs.

Relate the electric field at the surface of a conductor to the surface charge density:

$$E = \frac{\sigma}{\epsilon_0}$$

Solve for σ under dielectric breakdown of the air conditions:

$$\sigma_{max} = \epsilon_0\, E_{breaddown}$$

Substitute numerical values and evaluate σ_{max}:

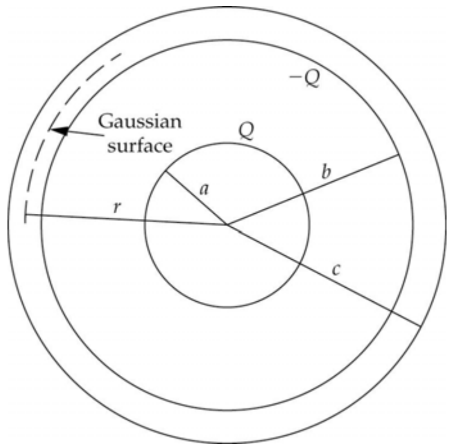
$$\sigma_{max} = \left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)(3\,\text{MV/m})$$

$$\approx \boxed{3\times10^{-5}\,\text{C/m}^2}$$

44 •• A conducting spherical shell of inner radius *b* and outer radius *c* is concentric with a small metal sphere of radius $a < b$. The metal sphere has a positive charge *Q*. The total charge on the conducting spherical shell is –*Q*. (Assume the potential is zero very far from all charges.) (*a*) What is the electric potential of the spherical shell? (*b*) What is the electric potential of the metal sphere?

Picture the Problem The diagram is a cross-sectional view showing the charges on the sphere and the spherical conducting shell. A portion of the Gaussian surface over which we'll integrate *E* in order to find *V* in the region $r > b$ is also shown. For $a < r < b$, the sphere acts like point charge *Q* and the potential of the metal sphere is the sum of the potential due to a point charge at its center and the

potential at its surface due to the charge on the inner surface of the spherical shell.



(*a*) Express $V_{r>b}$:

$$V_{r>b} = -\int E_{r>b}dr$$

Apply Gauss's law for $r > b$:

$$\oint_S \vec{\boldsymbol{E}}_r \cdot \hat{\boldsymbol{n}}dA = \frac{Q_{\text{enclosed}}}{\epsilon_0} = 0$$

and $E_{r>b} = 0$ because $Q_{\text{enclosed}} = 0$ for $r > b$.

Substitute for $E_{r>b}$ to obtain:

$$V_{r>b} = -\int (0)dr = \boxed{0}$$

(*b*) Express the potential of the metal sphere:

$$V_a = V_{Q\text{ at its center}} + V_{\text{surface}}$$

Express the potential at the surface of the metal sphere:

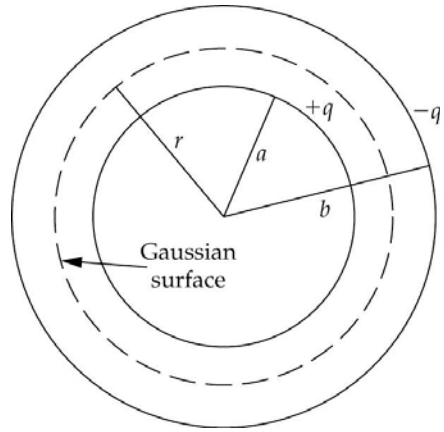
$$V_{\text{surface}} = \frac{k(-Q)}{b} = -\frac{kQ}{b}$$

Substitute and simplify to obtain:

$$V_a = \frac{kQ}{a} - \frac{kQ}{b} = \boxed{kQ\left(\frac{1}{a} - \frac{1}{b}\right)}$$

45 •• [SSM] Two coaxial conducting cylindrical shells have equal and opposite charges. The inner shell has charge $+q$ and an outer radius a, and the outer shell has charge $-q$ and an inner radius b. The length of each cylindrical shell is L, and L is very long compared with b. Find the potential difference, $V_a - V_b$ between the shells.

Picture the Problem The diagram is a cross-sectional view showing the charges on the inner and outer conducting shells. A portion of the Gaussian surface over which we'll integrate E in order to find V in the region $a < r < b$ is also shown. Once we've determined how E varies with r, we can find $V_a - V_b$ from $V_b - V_a = -\int E_r dr$.



Express the potential difference $V_b - V_a$:

$$V_b - V_a = -\int E_r dr \Rightarrow V_a - V_b = \int E_r dr$$

Apply Gauss's law to cylindrical Gaussian surface of radius r and length L:

$$\oint_S \vec{E} \cdot \hat{n} dA = E_r (2\pi r L) = \frac{q}{\epsilon_0}$$

Solving for E_r yields:

$$E_r = \frac{q}{2\pi \epsilon_0 rL}$$

Substitute for E_r and integrate from $r = a$ to b:

$$V_a - V_b = \frac{q}{2\pi \epsilon_0 L} \int_a^b \frac{dr}{r}$$

$$= \boxed{\frac{2kq}{L} \ln\left(\frac{b}{a}\right)}$$

46 •• Positive charge is placed on two conducting spheres that are very far apart and connected by a long very-thin conducting wire. The radius of the smaller sphere is 5.00 cm and the radius of the larger sphere is 12.0 cm. The electric field strength at the surface of the larger sphere is 200 kV/m. Estimate the surface charge density on each sphere.

Picture the Problem Let L and S refer to the larger and smaller spheres, respectively. We can use the fact that both spheres are at the same potential to estimate the electric fields near their surfaces. Knowing the electric fields, we can use $\sigma = \epsilon_0 E$ to estimate the surface charge density of each sphere.

Express the electric fields at the surfaces of the two spheres:

$$E_S = \frac{kQ_S}{R_S^2} \text{ and } E_L = \frac{kQ_L}{R_L^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{E_S}{E_L}=\frac{\frac{kQ_S}{R_S^2}}{\frac{kQ_L}{R_L^2}}=\frac{Q_S R_L^2}{Q_L R_S^2}$$

Because the potentials are equal at the surfaces of the spheres:

$$\frac{kQ_L}{R_L}=\frac{kQ_S}{R_S} \text{ and } \frac{Q_S}{Q_L}=\frac{R_S}{R_L}$$

Substitute for $\frac{Q_S}{Q_L}$ to obtain:

$$\frac{E_S}{E_L}=\frac{R_S R_L^2}{R_L R_S^2}=\frac{R_L}{R_S}\Rightarrow E_S=\frac{R_L}{R_S}E_L$$

Substitute numerical values and evaluate E_S:

$$E_S=\frac{12.0\,\text{cm}}{5.00\,\text{cm}}(200\,\text{kV/m})=480\,\text{kV/m}$$

Use $\sigma=\epsilon_0 E$ to estimate the surface charge density of each sphere:

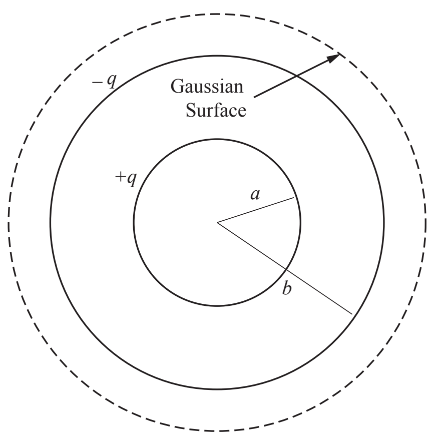
$$\sigma_{12\,\text{cm}}=\epsilon_0 E_{12\,\text{cm}}=\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)(200\,\text{kV/m})=\boxed{1.77\,\mu\text{C/m}^2}$$

and

$$\sigma_{5\,\text{cm}}=\epsilon_0 E_{5\,\text{cm}}=\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)(480\,\text{kV/m})=\boxed{4.25\,\mu\text{C/m}^2}$$

47 •• Two concentric conducting spherical shells have equal and opposite charges. The inner shell has outer radius a and charge $+q$; the outer shell has inner radius b and charge $-q$. Find the potential difference, $V_a - V_b$ between the shells.

Picture the Problem The diagram is a cross-sectional view showing the charges on the concentric spherical shells. The Gaussian surface over which we'll integrate E in order to find V in the region $r \geq b$ is also shown. We'll also find E in the region for which $a < r < b$. We can then use the relationship $V=-\int E dr$ to find V_a and V_b and their difference.



Express V_b:

$$V_b = -\int_{\infty}^{b} E_{r\geq b}\,dr$$

Apply Gauss's law for $r \geq b$:

$$\oint_S \vec{E}_r \cdot \hat{\mathbf{n}}\,dA = \frac{Q_{\text{enclosed}}}{\epsilon_0} = 0$$

and $E_{r\geq b} = 0$ because $Q_{\text{enclosed}} = 0$ for $r \geq b$.

Substitute for $E_{r\geq b}$ to obtain:

$$V_b = -\int_{\infty}^{b} (0)\,dr = 0$$

Express V_a:

$$V_a = -\int_{b}^{a} E_{r\geq a}\,dr$$

Apply Gauss's law for $r \geq a$:

$$E_{r\geq a}\left(4\pi r^2\right) = \frac{q}{\epsilon_0}$$

and

$$E_{r\geq a} = \frac{q}{4\pi \epsilon_0 r^2} = \frac{kq}{r^2}$$

Substitute for $E_{r\geq a}$ to obtain:

$$V_a = -kq\int_{b}^{a} \frac{dr}{r^2} = \frac{kq}{a} - \frac{kq}{b}$$

The potential difference between the shells is given by:

$$V_a - V_b = V_a = \boxed{kq\left(\frac{1}{a} - \frac{1}{b}\right)}$$

48 •• The electric potential at the surface of a uniformly charged sphere is 450 V. At a point outside the sphere at a (radial) distance of 20.0 cm from its surface, the electric potential is 150 V. (The potential is zero very far from the sphere.) What is the radius of the sphere, and what is the charge of the sphere?

Picture the Problem Let R be the radius of the sphere and Q its charge. We can express the potential at the two locations given and solve the resulting equations simultaneously for R and Q.

Relate the potential of the sphere at its surface to its radius:

$$\frac{kQ}{R} = 450\,\text{V} \qquad (1)$$

Express the potential at a distance of 20.0 cm from its surface:

$$\frac{kQ}{R+0.200\,\text{m}}=150\,\text{V} \qquad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{\dfrac{kQ}{R}}{\dfrac{kQ}{R+0.200\,\text{m}}}=\frac{450\,\text{V}}{150\,\text{V}}$$

or

$$\frac{R+0.200\,\text{m}}{R}=3\Rightarrow R=\boxed{10.0\,\text{cm}}$$

Solving equation (1) for Q yields:

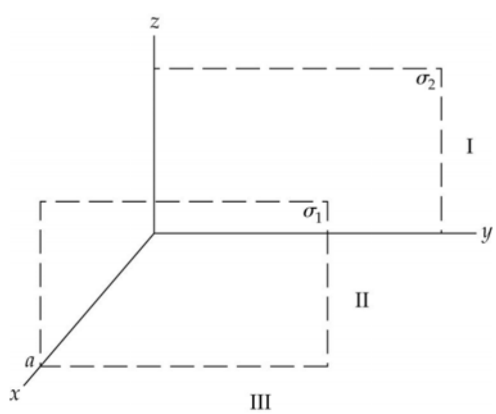
$$Q=(450\,\text{V})\frac{R}{k}$$

Substitute numerical values and evaluate Q:

$$Q=(450\,\text{V})\frac{(0.100\,\text{m})}{(8.988\times10^{9}\,\text{N}\cdot\text{m}^2/\text{C}^2)}$$
$$=\boxed{5.01\,\text{nC}}$$

49 •• Consider two infinite parallel thin sheets of charge, one in the $x = 0$ plane and the other in the $x = a$ plane. The potential is zero at the origin. (*a*) Find the electric potential everywhere in space if the planes have equal positive charge densities $+\sigma$. (*b*) Find the electric potential everywhere in space if the sheet in the $x = 0$ plane has a charge density $+\sigma$ and the sheet in the $x = a$ plane has a charge density $-\sigma$.

Picture the Problem Let the charge density on the infinite plane at $x = a$ be σ_1 and that on the infinite plane at $x = 0$ be σ_2. Call that region in space for which $x < 0$, region I, the region for which $0 < x < a$, region II, and the region for which $a < x$, region III. We can integrate E due to the planes of charge to find the electric potential in each of these regions.



(*a*) Express the potential in region I in terms of the electric field in that region:

$$V_{\text{I}} = -\int_0^x \vec{E}_{\text{I}} \cdot d\vec{x}$$

Express the electric field in region I as the sum of the fields due to the charge densities σ_1 and σ_2:

$$\vec{E}_{\text{I}} = -\frac{\sigma_1}{2\in_0}\hat{i} - \frac{\sigma_2}{2\in_0}\hat{i} = -\frac{\sigma}{2\in_0}\hat{i} - \frac{\sigma}{2\in_0}\hat{i} = -\frac{\sigma}{\in_0}\hat{i}$$

Substitute for $\vec{E}_{\text{I}}$ and evaluate V_{I}:

$$V_{\text{I}} = -\int_0^x \left(-\frac{\sigma}{\in_0}\right)dx = \frac{\sigma}{\in_0}x + V(0) = \frac{\sigma}{\in_0}x + 0 = \boxed{\frac{\sigma}{\in_0}x}$$

Express the potential in region II in terms of the electric field in that region:

$$V_{\text{II}} = -\int \vec{E}_{\text{II}} \cdot d\vec{x} + V(0)$$

Express the electric field in region II as the sum of the fields due to the charge densities σ_1 and σ_2:

$$\vec{E}_{\text{II}} = -\frac{\sigma_1}{2\in_0}\hat{i} + \frac{\sigma_2}{2\in_0}\hat{i} = -\frac{\sigma}{2\in_0}\hat{i} + \frac{\sigma}{2\in_0}\hat{i} = 0$$

Substitute for $\vec{E}_{\text{II}}$ and evaluate V_{II}:

$$V_{\text{II}} = -\int_0^x (0)dx = 0 + V(0) = \boxed{0}$$

Express the potential in region III in terms of the electric field in that region:

$$V_{\text{III}} = -\int_a^x \vec{E}_{\text{III}} \cdot d\vec{x}$$

Express the electric field in region III as the sum of the fields due to the charge densities σ_1 and σ_2:

$$\vec{E}_{\text{III}} = \frac{\sigma_1}{2\in_0}\hat{i} + \frac{\sigma_2}{2\in_0}\hat{i} = \frac{\sigma}{2\in_0}\hat{i} + \frac{\sigma}{2\in_0}\hat{i} = \frac{\sigma}{\in_0}\hat{i}$$

Substitute for $\vec{E}_{\text{III}}$ and evaluate V_{III}:

$$V_{\text{III}} = -\int_a^x \left(\frac{\sigma}{\epsilon_0}\right)dx = -\frac{\sigma}{\epsilon_0}x + \frac{\sigma}{\epsilon_0}a = \boxed{-\frac{\sigma}{\epsilon_0}(x-a)}$$

(*b*) Proceed as in (*a*) with $\sigma_1 = -\sigma$ and $\sigma_2 = \sigma$ to obtain:

$$V_{\text{I}} = \boxed{0},\ V_{\text{II}} = \boxed{-\frac{\sigma}{\epsilon_0}x}, \text{ and}$$

$$V_{\text{III}} = \boxed{0}$$

These results are summarized in the following table:

Region	$x \le 0$	$0 \le x \le a$	$x \ge a$
Part (*a*)	$\frac{\sigma}{\epsilon_0}x$	0	$-\frac{\sigma}{\epsilon_0}(x-a)$
Part (*b*)	0	$-\frac{\sigma}{\epsilon_0}x$	0

50 ••• The expression for the potential along the axis of a thin uniformly charge disk is given by $V = 2\pi k\sigma|z|\left(\sqrt{1+\frac{R^2}{z^2}}-1\right)$ (Equation 23-20), where R and σ are the radius and the charge per unit area of the disk, respectively. Show that this expression reduces to $V = kQ/|z|$ for $|z| >> R$, where $Q = \sigma\pi R^2$ is the total charge on the disk. Explain why this result is expected. *Hint: Use the binomial theorem to expand the radical.*

Picture the Problem

Expand the radical expression binomially to obtain:

$$\sqrt{1+\frac{R^2}{z^2}} = 1 + \left(\frac{1}{2}\right)\left(\frac{R^2}{z^2}\right) + \frac{\left(\frac{1}{2}\right)\left(-\frac{1}{2}\right)}{2!}\left(\frac{R^2}{z^2}\right)^2 + \text{higher order terms}$$

For $|z| >> R$:

$$\sqrt{1+\frac{R^2}{z^2}} \approx 1 + \left(\frac{1}{2}\right)\left(\frac{R^2}{z^2}\right)$$

and

$$\sqrt{1+\frac{R^2}{z^2}} - 1 \approx \frac{R^2}{2z^2}$$

Substituting in Equation 23-20 yields:

$$V = 2\pi k\sigma|z|\left(\frac{R^2}{2z^2}\right) = \pi k\sigma|z|\left(\frac{R^2}{z^2}\right)$$

The total charge on the disk is given by:

$$Q = \sigma\pi R^2 \Rightarrow \sigma = \frac{Q}{\pi R^2}$$

Substitute for σ and simplify to obtain:

$$V = \pi k\left(\frac{Q}{\pi R^2}\right)|z|\left(\frac{R^2}{z^2}\right) = \frac{k|z|Q}{z^2}$$

If $z \geq 0$, then $|z| = z$ and:

$$V = \frac{kzQ}{z^2} = \frac{kQ}{z} = \frac{kQ}{|z|}$$

If $z < 0$, then $|z| = -z$ and:

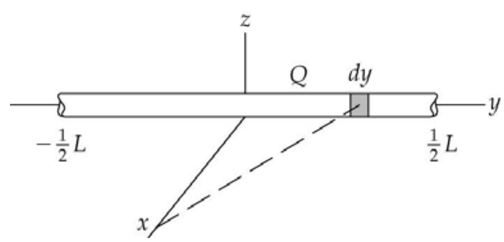
$$V = \frac{k(-z)Q}{z^2} = \frac{kQ}{-z} = \frac{kQ}{|z|}$$

Thus, for $|z| >> R$, Equation 23-20 reduces to:

$$V = \boxed{\frac{kQ}{|z|}}$$

51 •• [SSM] A rod of length L has a total charge Q uniformly distributed along its length. The rod lies along the y-axis with its center at the origin. (*a*) Find an expression for the electric potential as a function of position along the x-axis. (*b*) Show that the result obtained in Part (*a*) reduces to $V = kQ/|x|$ for $|x| >> L$. Explain why this result is expected.

Picture the Problem Let the charge per unit length be $\lambda = Q/L$ and dy be a line element with charge λdy. We can express the potential dV at any point on the x axis due to the charge element λdy and integrate to find $V(x, 0)$.



(*a*) Express the element of potential dV due to the line element dy:

$$dV = \frac{k\lambda}{r}dy$$

where $r = \sqrt{x^2 + y^2}$ and $\lambda = \frac{Q}{L}$.

Substituting for r and λ yields:

$$dV = \frac{kQ}{L}\frac{dy}{\sqrt{x^2 + y^2}}$$

Use a table of integrals to integrate dV from $y = -L/2$ to $y = L/2$:

$$V(x,0) = \frac{kQ}{L}\int_{-L/2}^{L/2}\frac{dy}{\sqrt{x^2+y^2}}$$

$$= \boxed{\frac{kQ}{L}\ln\left(\frac{\sqrt{x^2+\frac{1}{4}L^2}+\frac{1}{2}L}{\sqrt{x^2+\frac{1}{4}L^2}-\frac{1}{4}L^2}\right)}$$

(*b*) Factor x from the numerator and denominator within the parentheses to obtain:

$$V(x,0) = \frac{kQ}{L}\ln\left(\frac{\sqrt{1+\frac{L^2}{4x^2}}+\frac{L}{2x}}{\sqrt{1+\frac{L^2}{4x^2}}-\frac{L}{2x}}\right)$$

Use $\ln\left(\frac{a}{b}\right) = \ln a - \ln b$ to obtain:

$$V(x,0) = \frac{kQ}{L}\left\{\ln\left(\sqrt{1+\frac{L^2}{4x^2}}+\frac{L}{2x}\right) - \ln\left(\sqrt{1+\frac{L^2}{4x^2}}-\frac{L}{2x}\right)\right\}$$

Let $\varepsilon = \frac{L^2}{4x^2}$ and use $(1+\varepsilon)^{1/2} = 1+\frac{1}{2}\varepsilon-\frac{1}{8}\varepsilon^2+...$ to expand $\sqrt{1+\frac{L^2}{4x^2}}$:

$$\left(1+\frac{L^2}{4x^2}\right)^{1/2} = 1+\frac{1}{2}\frac{L^2}{4x^2}-\frac{1}{8}\left(\frac{L^2}{4x^2}\right)^2+... \approx 1 \text{ for } |x| >> L.$$

Substitute for $\left(1+\frac{L^2}{4x^2}\right)^{1/2}$ to obtain:

$$V(x,0) = \frac{kQ}{L}\left\{\ln\left(1+\frac{L}{2x}\right) - \ln\left(1-\frac{L}{2x}\right)\right\}$$

Let $\delta = \frac{L}{2x}$ and use $\ln(1+\delta) = \delta - \frac{1}{2}\delta^2+...$ to expand $\ln\left(1\pm\frac{L}{2x}\right)$:

$$\ln\left(1+\frac{L}{2x}\right) \approx \frac{L}{2x}-\frac{L^2}{4x^2} \text{ and } \ln\left(1-\frac{L}{2x}\right) \approx -\frac{L}{2x}-\frac{L^2}{4x^2} \text{ for } x >> L.$$

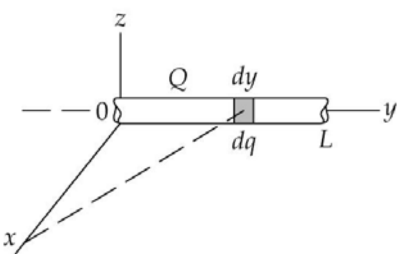
Substitute for $\ln\left(1+\frac{L}{2x}\right)$ and $\ln\left(1-\frac{L}{2x}\right)$ and simplify to obtain:

$$V(x,0)=\frac{kQ}{L}\left\{\frac{L}{2x}-\frac{L^2}{4x^2}-\left(-\frac{L}{2x}-\frac{L^2}{4x^2}\right)\right\}=\boxed{\frac{kQ}{x}}$$

Because, for $|x|>>L$, the charge carried by the rod is far enough away from the point of interest to look like a point charge, this result is what we would expect.

52 •• A rod of length L has a charge Q uniformly distributed along its length. The rod lies along the y-axis with one end at the origin. (*a*) Find an expression for the electric potential as a function of position along the x-axis. (*b*) Show that the result obtained in Part (*a*) reduces to $V=kQ/|x|$ for $|x|>>L$. Explain why this result is expected.

Picture the Problem Let the charge per unit length be $\lambda = Q/L$ and dy be a line element with charge λdy. We can express the potential dV at any point on the x axis due to λdy and integrate to find $V(x, 0)$.



(*a*) Express the element of potential dV due to the line element dy:

$$dV=\frac{k\lambda}{r}dy$$

where $r=\sqrt{x^2+y^2}$ and $\lambda=\frac{Q}{L}$.

Substituting for r and λ yields:

$$dV=\frac{kQ}{L}\frac{dy}{\sqrt{x^2+y^2}}$$

Use a table of integrals to integrate dV from $y = 0$ to $y = L$:

$$V(x,0)=\frac{kQ}{L}\int_0^L\frac{dy}{\sqrt{x^2+y^2}}$$
$$=\frac{kQ}{L}\ln\left(y+\sqrt{x^2+y^2}\right)_0^L$$
$$=\frac{kQ}{L}\left[\ln\left(L+\sqrt{x^2+L^2}\right)-\ln(x)\right]$$

Because $\ln a-\ln b=\ln\left(\frac{a}{b}\right)$:

$$V(x,0)=\boxed{\frac{kQ}{L}\left[\ln\left(\frac{L+\sqrt{x^2+L^2}}{x}\right)\right]} \quad (1)$$

(b) Factor x^2 under the radical to obtain:

$$\ln\left(\frac{L+\sqrt{x^2+L^2}}{x}\right)=\ln\left(\frac{L+\sqrt{x^2\left(1+\left(\frac{L}{x}\right)^2\right)}}{x}\right)=\ln\left(\frac{L+\sqrt{x^2}\sqrt{\left(1+\left(\frac{L}{x}\right)^2\right)}}{x}\right)$$

Because $|x|>>L$:

$$\ln\left(\frac{L+\sqrt{x^2+L^2}}{x}\right)\approx\ln\left(\frac{L+\sqrt{x^2}}{x}\right)$$
$$=\ln\left(1+\frac{L}{x}\right)$$

Expanding $\ln\left(1+\frac{L}{x}\right)$ binomially yields:

$$\ln\left(1+\frac{L}{x}\right)=\frac{L}{x}-\frac{1}{2}\left(\frac{L}{x}\right)^2$$
$$+\text{higher order terms}$$

Again, because $|x|>>L$:

$$\ln\left(1+\frac{L}{x}\right)\approx\frac{L}{x}$$

Substitute in equation (2) to obtain:

$$\ln\left(\frac{L+\sqrt{x^2+L^2}}{x}\right)\approx\frac{L}{x}$$

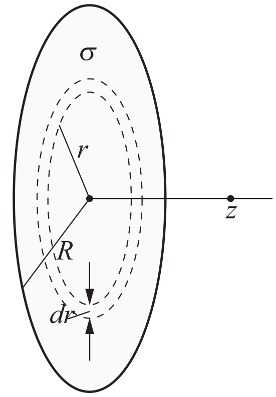
Finally, substituting in equation (1) yields:

$$V(x,0)=\frac{kQ}{L}\left[\frac{L}{x}\right]=\boxed{\frac{kQ}{x}}$$

Because, for $|x|>>L$, the charge carried by the rod is far enough away from the point of interest to look like a point charge, this result is what we would expect.

53 •• **[SSM]** A disk of radius R has a surface charge distribution given by $\sigma=\sigma_0 r^2/R^2$ where σ_0 is a constant and r is the distance from the center of the disk. (a) Find the total charge on the disk. (b) Find an expression for the electric potential at a distance z from the center of the disk on the axis that passes through the disk′s center and is perpendicular to its plane.

Picture the Problem We can find Q by integrating the charge on a ring of radius r and thickness dr from $r = 0$ to $r = R$ and the potential on the axis of the disk by integrating the expression for the potential on the axis of a ring of charge between the same limits.



(a) Express the charge dq on a ring of radius r and thickness dr:

$$dq = 2\pi r\sigma dr = 2\pi r\left(\sigma_0 \frac{r^2}{R^2}\right)dr$$

$$= \frac{2\pi\sigma_0}{R^2} r^3 dr$$

Integrate from $r = 0$ to $r = R$ to obtain:

$$Q = \frac{2\pi\sigma_0}{R^2}\int_0^R r^3 dr = \boxed{\tfrac{1}{2}\pi\sigma_0 R^2}$$

(b)Express the potential on the axis of the disk due to a circular element of charge $dq = \frac{2\pi\sigma_0}{R^2} r^3 dr$:

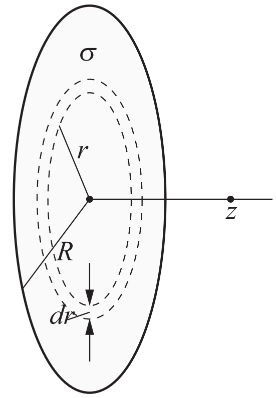
$$dV = \frac{kdq}{r'} = \frac{2\pi k\sigma_0}{R^2}\frac{r^3}{\sqrt{x^2 + r^2}}dr$$

Integrate from $r = 0$ to $r = R$ to obtain:

$$V = \frac{2\pi k\sigma_0}{R^2}\int_0^R \frac{r^3 dr}{\sqrt{x^2 + r^2}} = \boxed{\frac{2\pi k\sigma_0}{3R^2}\left[\left(R^2 - 2x^2\right)\sqrt{x^2 + R^2} + 2x^3\right]}$$

54 ••• A disk of radius R has a surface charge distribution given by $\sigma = \sigma_0 R/r$ where σ_0 is a constant and r is the distance from the center of the disk. (a) Find the total charge on the disk. (b) Find an expression for the electric potential at a distance x from the center of the disk on the axis that passes through the disk′s center and is perpendicular to its plane.

Picture the Problem We can find Q by integrating the charge on a ring of radius r and thickness dr from $r = 0$ to $r = R$ and the potential on the axis of the disk by integrating the expression for the potential on the axis of a ring of charge between the same limits.



(*a*) Express the charge dq on a ring of radius r and thickness dr:

$$dq = 2\pi r\sigma dr = 2\pi r\left(\sigma_0\frac{R}{r}\right)dr$$
$$= 2\pi\sigma_0 R dr$$

Integrate from $r = 0$ to $r = R$ to obtain:

$$Q = 2\pi\sigma_0 R\int_0^R dr = \boxed{2\pi\sigma_0 R^2}$$

(*b*) Express the potential on the axis of the disk due to a circular element of charge $dq = 2\pi r\sigma dr$:

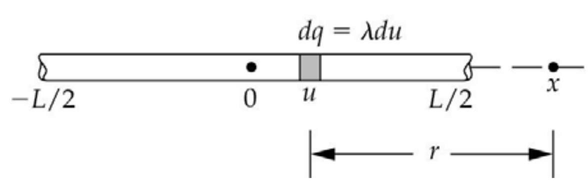
$$dV = \frac{kdq}{r'} = \frac{2\pi k\sigma_0 R dr}{\sqrt{x^2 + r^2}}$$

Integrate from $r = 0$ to $r = R$ to obtain:

$$V = 2\pi k\sigma_0 R\int_0^R \frac{dr}{\sqrt{x^2 + r^2}}$$
$$= \boxed{2\pi k\sigma_0 R\ln\left(\frac{R + \sqrt{x^2 + R^2}}{x}\right)}$$

55 •• A rod of length L has a total charge Q uniformly distributed along its length. The rod lies along the x-axis with its center at the origin. (*a*) What is the electric potential as a function of position along the x-axis for $x > L/2$? (*b*) Show that for $x >> L/2$, your result reduces to that due to a point charge Q.

Picture the Problem We can express the electric potential dV at x due to an elemental charge dq on the rod and then integrate over the length of the rod to find $V(x)$. In the second part of the problem we use a binomial expansion to show that, for $x >> L/2$, our result reduces to that due to a point charge Q.



(a) Express the potential at x due to the element of charge dq located at u:

$$dV = \frac{kdq}{r} = \frac{k\lambda du}{x-u}$$

or, because $\lambda = Q/L$,

$$dV = \frac{kQ}{L}\frac{du}{x-u}$$

Integrate V from $u = -L/2$ to $u = L/2$ and simplify to obtain:

$$\begin{aligned} V(x) &= \frac{kQ}{L}\int_{-L/2}^{L/2}\frac{du}{x-u} \\ &= -\frac{kQ}{L}\ln(x-u)\Big|_{-L/2}^{L/2} \\ &= \frac{kQ}{L}\left[-\ln\left(x-\tfrac{1}{2}L\right)+\ln\left(x+\tfrac{1}{2}L\right)\right] \\ &= \boxed{\frac{kQ}{L}\ln\left(\frac{x+\frac{1}{2}L}{x-\frac{1}{2}L}\right)} \end{aligned}$$

(b) From Part (a):

$$\begin{aligned} V(x) &= \frac{kQ}{L}\left[\ln\left(x+\tfrac{1}{2}L\right)-\ln\left(x-\tfrac{1}{2}L\right)\right] \\ &= \frac{kQ}{L}\left[\ln x\left(1+\frac{L}{2x}\right)-\ln x\left(1-\frac{L}{2x}\right)\right] \end{aligned}$$

Expanding the expression in the square brackets and simplifying gives:

$$V(x) = \frac{kQ}{L}\left[\ln x+\ln\left(1+\frac{L}{2x}\right)-\ln x+\ln\left(1-\frac{L}{2x}\right)\right] = \frac{kQ}{L}\left[\ln\left(1+\frac{L}{2x}\right)+\ln\left(1-\frac{L}{2x}\right)\right]$$

For $\dfrac{L}{2x} << 1$:

$$\ln\left(1\pm\frac{L}{2x}\right) \approx \pm\frac{L}{2x}$$

Substitute for $\ln\left(1\pm\dfrac{L}{2x}\right)$ to obtain:

$$V(x) \approx \frac{kQ}{L}\left[\frac{L}{2x}+\frac{L}{2x}\right] = \boxed{\frac{kQ}{x}},$$

the potential due to a point charge Q.

56 ••• A circle of radius a is removed from the center of a uniformly charged thin circular disk of radius b and charge per unit area σ. (a) Find an expression for the potential on the x axis a distance x from the center of the disk. (b) Show that for $x >> b$ the electric potential on the axis of the uniformly charged disk with cutout approaches kQ/x, where $Q = \sigma\pi(b^2 - a^2)$ is the total charge on the disk.

Picture the Problem The potential on the axis of the uniformly charged disk is the sum of the potential V_b due to the disk of radius *b* and the potential V_a due to the disk of radius *a* that has been removed. We can think of the charged disk that has been removed as having a negative charge density $-\sigma$. Note that if $x >> b$, then it is also true that $x >> a$.

(*a*)The potential on the axis of the circular disk is:

$$V(x) = V_b(x) + V_a(x)$$

where

$$V_b(x) = 2\pi k\sigma\left[\left(x^2 + b^2\right)^{1/2} - x\right]$$

and

$$V_a(x) = 2\pi k(-\sigma)\left[\left(x^2 + a^2\right)^{1/2} - x\right]$$

Substitute for $V_b(x)$ and $V_a(x)$ and simplify to obtain:

$$\begin{aligned} V(x) &= 2\pi k\sigma\left[\left(x^2 + b^2\right)^{1/2} - x\right] + 2\pi k(-\sigma)\left[\left(x^2 + a^2\right)^{1/2} - x\right] \\ &= 2\pi k\sigma\left[\left(x^2 + b^2\right)^{1/2} - \left(x^2 + a^2\right)^{1/2}\right] \\ &= \boxed{2\pi k\sigma\left(\sqrt{x^2 + b^2} - \sqrt{x^2 + a^2}\right)} \end{aligned}$$

(*b*) Expanding $\left(1 + \frac{b^2}{x^2}\right)^{1/2}$ binomially yields:

$$\left(1 + \frac{b^2}{x^2}\right)^{1/2} = 1 + \frac{b^2}{2x^2} + \text{higher order terms} \approx 1 + \frac{b^2}{2x^2}$$

Expanding $\left(1 + \frac{a^2}{x^2}\right)^{1/2}$ binomially yields:

$$\left(1 + \frac{a^2}{x^2}\right)^{1/2} \approx 1 + \frac{a^2}{2x^2}$$

Substituting in the expression for $V(x)$ and simplifying yields:

$$V(x) \approx 2\pi k\sigma x\left[1 + \frac{b^2}{2x^2} - \left(1 + \frac{a^2}{2x^2}\right)\right] = 2\pi k\sigma x\left[\frac{b^2}{2x^2} - \frac{a^2}{2x^2}\right] = \frac{\pi k\sigma\left(b^2 - a^2\right)}{x}$$

The total charge on the disk is:

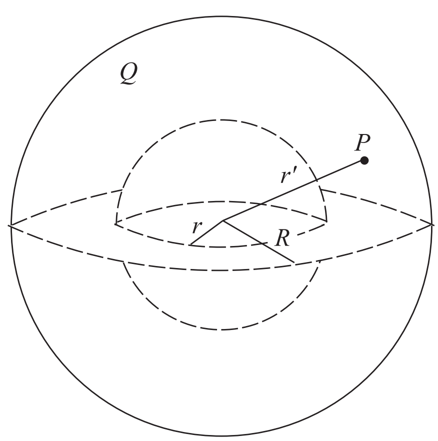
$$Q = \sigma\pi\left(b^2 - a^2\right) \Rightarrow \sigma = \frac{Q}{\pi\left(b^2 - a^2\right)}$$

Substituting for σ yields:

$$V(x) \approx \frac{\pi k\left(\dfrac{Q}{\pi\left(b^2 - a^2\right)}\right)\left(b^2 - a^2\right)}{x} = \boxed{\frac{kQ}{x}}$$

57 ••• The expression for the electric potential inside a uniformly charged solid sphere is given by $V(r) = \dfrac{kQ}{2R}\left(3 - \dfrac{r^2}{R^2}\right)$, where R is the radius of the sphere and r is the distance from the center. This expression was obtained in Example 23-12 by first finding the electric field. In this problem, you derive the same expression by modeling the sphere as a nested collection of thin spherical shells, and then adding the potentials of these shells at a field point inside the sphere. The potential dV that is a distance r' from the center of a uniformly charged thin spherical shell that has a radius r' and a charge dQ is given by $dV = kdQ/r'$ for $r' \geq r$ and $dV = kdQ/r$ for $r' \leq r$ (Equation 23-22). Consider a sphere of radius R containing a charge Q that is uniformly distributed and you want to find V at some point inside the sphere (that is for $r < R$). (*a*) Find an expression for the charge dQ on a spherical shell of radius r' and thickness dr'. (*b*) Find an expression for the potential dV at r due to the charge in a shell of radius r' and thickness dr', where $r \leq r' \leq R$. (*c*) Integrate your expression in Part (*b*) from $r' = r$ to $r' = R$ to find the potential at r due to all the charge in the region farther from r than the center of the sphere. (*d*) Find an expression for the potential dV at r due to the charge in a shell of radius r' and thickness dr', where $r' \leq r$. (*e*) Integrate your expression in Part (*d*) from $r' = 0$ to $r' = r$ to find the potential at r due to all the charge in the region closer than r to the center of the sphere. (*f*) Find the total potential V at r by adding your Part (*c*) and Part (*e*) results.

Picture the Problem The diagram shows a uniformly charged sphere of radius R and the field point P at which we wish to find the total potential. We can use the definition of charge density to find the charge inside a sphere of radius r and the potential at r due to this charge. We can express the potential at r due to the charge in a shell of radius r' and thickness dr' at $r' \geq r$ using $dV = kdq'/r$ and then integrate this expression from $r' = r$ to $r' = R$ to find V.



(*a*) The charge dQ in a shell of radius r' and thickness dr' at $r' > r$ is given by:

$$dQ = \rho dV' = \rho A' dr'$$

Because $A' = 4\pi r'^2$:

$$dQ = 4\pi r'^2 \rho dr'$$

Because the sphere is uniformly charged:

$$\rho = \frac{Q}{V} = \frac{Q}{\frac{4}{3}\pi R^3} = \frac{3Q}{4\pi R^3}$$

Substituting for ρ and simplifying yields:

$$dQ = 4\pi r'^2 \left(\frac{3Q}{4\pi R^3}\right) dr' = \boxed{\frac{3Q}{R^3} r'^2 dr'}$$

(*b*) Express the potential dV in the interval $r \le r' \le R$ due to dQ:

$$dV = \frac{kdQ}{r'}$$

Substituting for dQ and simplifying yields:

$$dV = \frac{k}{r'}\left(\frac{3Q}{R^3} r'^2 dr'\right) = \boxed{\frac{3kQ}{R^3} r' dr'}$$

(*c*) Integrate dV from $r' = r$ to $r' = R$ to find V:

$$V = \frac{3kQ}{R^3}\int_r^R r' dr' = \boxed{\frac{3kQ}{2R^3}\left(R^2 - r^2\right)}$$

(*d*) The potential dV at r due to the charge in a shell of radius r' and thickness dr', where $r' \le r$, is given by:

$$dV = \frac{kdQ}{r} = \frac{k\rho dV'}{r} = \frac{k\rho A' dr'}{r}$$
$$= \frac{k\rho\left(4\pi r'^2\right)dr'}{r} = \frac{4\pi k\rho}{r} r'^2 dr'$$

Substituting for ρ and simplifying yields:

$$dV = \frac{4\pi k}{r}\left(\frac{Q}{\frac{4}{3}\pi R^3}\right) r'^2 dr'$$
$$= \boxed{\left(\frac{3kQ}{R^3 r}\right) r'^2 dr'}$$

(*e*) Integrate from $r' = 0$ to $r' = r$ to find the potential at r due to all the charge in the region closer than r to the center of the sphere:

$$V = \left(\frac{3kQ}{R^3 r}\right)\int_0^r r'^2 dr' = \boxed{\frac{kQ}{R^3} r^2}$$

(*f*) The sum of our results from Part (*c*) and Part (*e*) is:

$$V = \frac{kQ}{R^3}r^2 + \frac{3kQ}{2R^3}\left(R^2 - r^2\right) = \boxed{\frac{kQ}{2R}\left(3 - \frac{r^2}{R^2}\right)}$$

58 •• Calculate the electric potential at the point a distance $R/2$ from the center of a uniformly charged thin spherical shell of radius R and charge Q. (Assume the potential is zero far from the shell.)

Picture the Problem We can find the potential relative to infinity at a distance $R/2$ from the center of the spherical shell by integrating the electric field for 0 to ∞. We can apply Gauss's law to find the electric field both inside and outside the spherical shell.

The potential relative to infinity at a distance $R/2$ from the center of the spherical shell is given by:

$$V = -\int_{\infty}^{R/2} \vec{\boldsymbol{E}} \cdot d\vec{\boldsymbol{r}} = -\int_{\infty}^{R} E_{r>R}\,dr - \int_{R}^{R/2} E_{r<R}\,dr$$

Because there is no charge inside the spherical shell, $E_{r<R} = 0$ and:

$$\int_{R}^{R/2} E_{r<R}\,dr = 0 \text{ and } V = -\int_{\infty}^{R} E_{r>R}\,dr \quad (1)$$

Apply Gauss's law to a spherical surface of radius $r > R$ to obtain:

$$\oint_S E_n\,dA = E_{r>R}\left(4\pi r^2\right) = \frac{Q_{\text{inside}}}{\epsilon_0} = \frac{Q}{\epsilon_0}$$

Solving for $E_{r>R}$ yields:

$$E_{r>R} = \frac{Q}{4\pi\epsilon_0 r^2} = \frac{kQ}{r^2}$$

Substitute for $E_{r>R}$ in equation (1) to obtain:

$$V = -kQ\int_{\infty}^{R} \frac{dr}{r^2}$$

Evaluating this integral yields:

$$V = -kQ\left[-\frac{1}{r}\right]_{\infty}^{R} = \boxed{\frac{kQ}{R}}$$

59 •• [SSM] A circle of radius a is removed from the center of a uniformly charged thin circular disk of radius b. Show that the potential at a point on the central axis of the disk a distance z from its geometrical center is given by $V(z) = 2\pi k\sigma\left(\sqrt{z^2 + b^2} - \sqrt{z^2 + a^2}\right)$, where σ is the charge density of the disk.

Picture the Problem We can find the electrostatic potential of the conducting washer by treating it as two disks with equal but opposite charge densities.

The electric potential due to a charged disk of radius R is given by:

$$V(x) = 2\pi k\sigma|x|\left(\sqrt{1+\frac{R^2}{x^2}}-1\right)$$

Superimpose the electrostatic potentials of the two disks with opposite charge densities and simplify to obtain:

$$\begin{aligned}
V(x) &= 2\pi k\sigma|x|\left(\sqrt{1+\frac{b^2}{x^2}}-1\right) - 2\pi k\sigma|x|\left(\sqrt{1+\frac{a^2}{x^2}}-1\right)\\
&= 2\pi k\sigma|x|\left(\left(\sqrt{1+\frac{b^2}{x^2}}-1\right)-\left(\sqrt{1+\frac{a^2}{x^2}}-1\right)\right)\\
&= 2\pi k\sigma|x|\left(\sqrt{1+\frac{b^2}{x^2}}-\sqrt{1+\frac{a^2}{x^2}}\right) = 2\pi k\sigma|x|\left(\sqrt{\frac{x^2+b^2}{x^2}}-\sqrt{\frac{x^2+a^2}{x^2}}\right)\\
&= 2\pi k\sigma|x|\left(\frac{\sqrt{x^2+b^2}}{\sqrt{x^2}}-\frac{\sqrt{x^2+a^2}}{\sqrt{x^2}}\right) = 2\pi k\sigma|x|\left(\frac{\sqrt{x^2+b^2}}{|x|}-\frac{\sqrt{x^2+a^2}}{|x|}\right)\\
&= 2\pi k\sigma\left(\sqrt{x^2+b^2}-\sqrt{x^2+a^2}\right)
\end{aligned}$$

The charge density σ is given by:

$$\sigma = \frac{Q}{\pi\left(b^2-a^2\right)}$$

Substituting for σ yields:

$$V(x) = \boxed{\frac{2kQ}{\left(b^2-a^2\right)}\left(\sqrt{x^2+b^2}-\sqrt{x^2+a^2}\right)}$$

Equipotential Surfaces

60 • An infinite flat sheet of charge has a uniform surface charge density equal to 3.50 μC/m^2. How far apart are the equipotential surfaces whose potentials differ by 100 V?

Picture the Problem We can equate the expression for the electric field due to an infinite plane of charge and $-\Delta V/\Delta x$ and solve the resulting equation for the separation of the equipotential surfaces.

Express the electric field due to the infinite plane of charge:

$$E = \frac{\sigma}{2\in_0}$$

Relate the electric field to the potential:

$$E = -\frac{\Delta V}{\Delta x}$$

Equate these expressions and solve for Δx to obtain:

$$\Delta x = \frac{2\in_0 \Delta V}{\sigma}$$

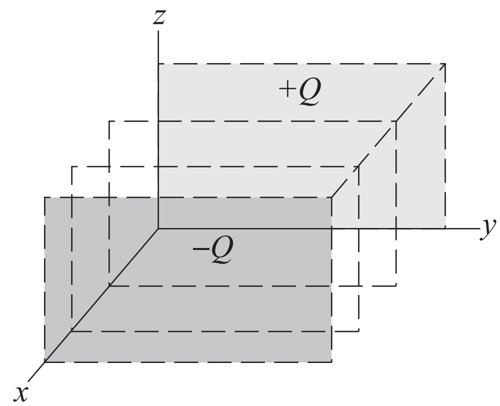
Substitute numerical values and evaluate $|\Delta x|$:

$$|\Delta \boldsymbol{x}| = \frac{2\left(8.854\times10^{-12}\,\frac{\mathrm{C}^2}{\mathrm{N\cdot m^2}}\right)(100\,\mathrm{V})}{3.50\,\mu\mathrm{C/m^2}}$$

$$= \boxed{0.506\,\mathrm{mm}}$$

61 •• [SSM] Consider two parallel uniformly charged infinite planes that are equal but oppositely charged. (*a*) What is (are) the shape(s) of the equipotentials in the region between them? Explain your answer. (*b*) What is (are) the shape(s) of the equipotentials in the regions not between them? Explain your answer.

Picture the Problem The two parallel planes, with their opposite charges, are shown in the pictorial representation.



(*a*) Because the electric field between the charged plates is uniform and perpendicular to the plates, the equipotential surfaces are planes parallel to the charged planes.

(*b*) The regions to either side of the two charged planes are equipotential regions, so any surface in either of these regions is an equipotential surface.

62 •• A Geiger tube consists of two elements, a long metal cylindrical shell and a long straight metal wire running down its central axis. Model the tube as if both the wire and cylinder are infinitely long. The central wire is positively charged and the outer cylinder is negatively charge. The potential difference between the wire and the cylinder is 1.00 kV. (*a*) What is the direction of the electric field inside the tube? (*b*) Which element is at a higher electric potential?

(*c*) What is (are) the shape(s) of the equipotentials inside the tube? (*d*) Consider two equipotentials described in Part (*c*). Suppose they differ in electric potential by 10 V. Do two such equipotentials near the central wire have the same spacing as they would near the outer cylinder? If not, where in the tube are the equipotentials that are more widely spaced? Explain your answer.

Determine the Concept
(*a*) The direction of the electric field inside the tube is the direction of the force the electric field exerts on a positively charged object. Because the wire is positively charged and the tube is negatively charged, and because of the cylindrical geometry of the Geiger tube, the electric field is directed radially away from the central wire.

(*b*) Because it would require more work to bring a positively charged object from infinity to the surface of the wire than it would to bring this test object to the surface of the cylindrical tube, the central wire is at the higher electric potential.

(*c*) Because of the cylindrical geometry of the Geiger tube, the equipotential surfaces are cylinders concentric with the central wire.

(*d*) No. Because the magnitude of the electric field, which is the rate of change with distance (also known as the gradient) of the potential decreases with distance from the wire, the spacing between adjacent equipotential surfaces having the same potential difference between them decreases as you get farther from the central wire.

63 •• [SSM] Suppose the cylinder in the Geiger tube in Problem 62 has an inside diameter of 4.00 cm and the wire has a diameter of 0.500 mm. The cylinder is grounded so its potential is equal to zero. (*a*) What is the radius of the equipotential surface that has a potential equal to 500 V? Is this surface closer to the wire or to the cylinder? (*b*) How far apart are the equipotential surfaces that have potentials of 200 and 225 V? (*c*) Compare your result in Part (*b*) to the distance between the two surfaces that have potentials of 700 and 725 V respectively. What does this comparison tell you about the electric field strength as a function of the distance from the central wire?

Picture the Problem If we let the electric potential of the cylinder be zero, then the surface of the central wire is at +1000 V and we can use Equation 23-23 to find the electric potential at any point between the outer cylinder and the central wire.

(*a*) From Equation 23-23 we have:

$$V(r) = 2k\lambda \ln\left(\frac{R_{\text{ref}}}{r}\right) \qquad (1)$$

where R_{ref} is the radius of the outer cylinder and r is the distance from the center of the central wire and $r < R_{\text{ref}}$.

Solving for $2k\lambda$ yields:

$$2k\lambda = \frac{V(r)}{\ln\left(\frac{R_{\text{ref}}}{r}\right)}$$

At the surface of the wire, $V = 1000$ V and $r = 0.250$ mm. Hence:

$$2k\lambda = \frac{1000\text{ V}}{\ln\left(\frac{2.00\text{ cm}}{0.250\text{ mm}}\right)} = 228.2\text{ V}$$

and

$$V(r) = (228.2\text{ V})\ln\left(\frac{2.00\text{ cm}}{r}\right)$$

Setting $V = 500$ V yields:

$$500\text{ V} = (228.2\text{ V})\ln\left(\frac{2.00\text{ cm}}{r}\right)$$

or

$$\ln\left(\frac{2.00\text{ cm}}{r}\right) = 2.191 \Rightarrow \frac{2.00\text{ cm}}{r} = e^{2.191}$$

Solve for r to obtain:

$r = \dfrac{2.00\text{ cm}}{e^{2.191}} = \boxed{0.224\text{ cm}}$, closer to the wire.

(*b*) The separation of the equipotential surfaces that have potential values of 200 and 225 V is:

$$\Delta r = \left|r_{225\text{ V}} - r_{200\text{ V}}\right| \qquad (2)$$

Solving equation (1) for r yields:

$$r = R_{\text{ref}}e^{-\frac{V}{2k\lambda}} = (2.00\text{ cm})e^{-\frac{V}{228.2\text{ V}}}$$

Substitute for the radii in equation (2), simplify, and evaluate Δr to obtain:

$$\Delta r = \left|(2.00\text{ cm})e^{-\frac{225\text{ V}}{228.2\text{ V}}} - (2.00\text{ cm})e^{-\frac{200\text{ V}}{228.2\text{ V}}}\right| = (2.00\text{ cm})\left|e^{-\frac{225\text{ V}}{228.2\text{ V}}} - e^{-\frac{200\text{ V}}{228.2\text{ V}}}\right|$$

$$= \boxed{0.864\text{ mm}}$$

(*c*) The distance between the 700 V and the 725 V equipotentials is:

$$\Delta r = (2.00\text{ cm})\left| e^{-\frac{725\text{ V}}{228.2\text{ V}}} - e^{-\frac{700\text{ V}}{228.2\text{ V}}} \right|$$

$$= \boxed{0.0966\text{ mm}}$$

This closer spacing of these two equipotential surfaces was to be expected. Close to the central wire, two equipotential surfaces with the same difference in potential should be closer together to reflect the fact that the higher electric field strength is greater closer to the wire.

64 •• A point particle that has a charge of $+11.1$ nC is at the origin. (*a*) What is (are) the shapes of the equipotential surfaces in the region around this charge? (*b*) Assuming the potential to be zero at $r = \infty$, calculate the radii of the five surfaces that have potentials equal to 20.0 V, 40.0 V, 60.0 V, 80.0 V and 100.0 V, and sketch them to scale centered on the charge. (*c*) Are these surfaces equally spaced? Explain your answer. (*d*) Estimate the electric field strength between the 40.0-V and 60.0-V equipotential surfaces by dividing the difference between the two potentials by the difference between the two radii. Compare this estimate to the exact value at the location midway between these two surfaces.

Picture the Problem We can integrate the expression for the electric field due to a point charge to find an expression for the electric potential of the point particle.

(*a*) The equipotential surfaces are spheres centered on the charge.

(*b*) From the relationship between the electric potential due to the point charge and the electric field of the point charge we have:

$$\int_a^b dV = -\int_{r_a}^{r_b} \vec{\boldsymbol{E}} \cdot d\vec{\mathbf{r}} = -kQ\int_{r_a}^{r_b} r^{-2}\,dr$$

or

$$V_b - V_a = kQ\left(\frac{1}{r_b} - \frac{1}{r_a}\right)$$

Taking the potential to be zero at $r_a = \infty$ yields:

$$V_b - 0 = kQ\left(\frac{1}{r_b}\right) \Rightarrow V = \frac{kQ}{r} \Rightarrow r = \frac{kQ}{V}$$

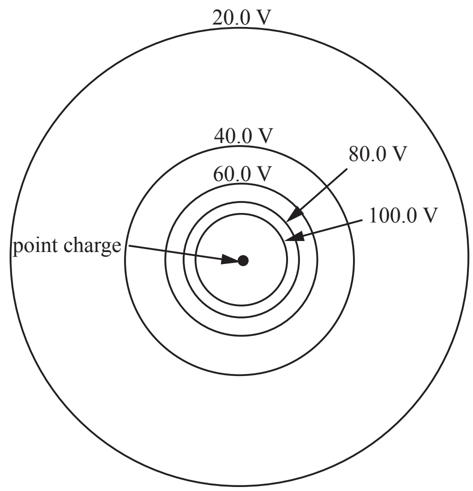
Because $Q = +1.11 \times 10^{-8}$ C:

$$r = \frac{\left(8.988\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.11\times10^{-8}\text{ C}\right)}{V} = \frac{99.77\,\frac{\text{N}\cdot\text{m}^2}{\text{C}}}{V} \quad (1)$$

Use equation (1) to complete the following table:

V (V)	20.0	40.0	60.0	80.0	100.0
r (m)	4.99	2.49	1.66	1.25	1.00

The equipotential surfaces are shown in cross-section to the right:



(c) No. The equipotential surfaces are closest together where the electric field strength is greatest.

(d) The average value of the magnitude of the electric field between the 40.0-V and 60.0-V equipotential surfaces is given by:

$$E = -\frac{\Delta V}{\Delta r} = -\frac{40\text{ V} - 60\text{ V}}{\Delta r}$$

Drop perpendiculars to the r axis from 40.0 V and 60.0 V to approximate the radii corresponding to each of these potential surfaces:

$$E_{\text{est}} \approx -\frac{40\text{ V} - 60\text{ V}}{2.4\text{ m} - 1.7\text{ m}} = 29\frac{\text{V}}{\text{m}}$$

The exact value of the electric field at the location midway between these two surfaces is given by $E = kQ/r^2$, where r is the average of the radii of the 40.0-V and 60.0-V equipotential surfaces. Substitute numerical values and evaluate E_{exact}.

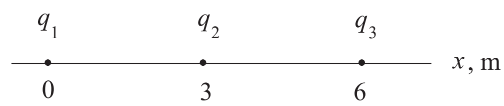
$$E_{\text{exact}} = \frac{\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.11\times10^{-8}\text{ C}\right)}{\left(\frac{1.66\text{ m} + 2.49\text{ m}}{2}\right)^2} = 23\frac{\text{V}}{\text{m}}$$

The estimated value for E differs by about 21% from the exact value.

Electrostatic Potential Energy

65 • Three point charges are on the x-axis: q_1 is at the origin, q_2 is at $x = +3.00$ m, and q_3 is at $x = +6.00$ m. Find the electrostatic potential energy of this system of charges for the following charge values: (a) $q_1 = q_2 = q_3 = +2.00\ \mu$C; ($b$) $q_1 = q_2 = +2.00\ \mu$C and $q_3 = -2.00\ \mu$C; and (c) $q_1 = q_3 = +2.00\ \mu$C and $q_2 = -2.00\ \mu$C. (Assume the potential energy is zero when the charges are very far from each other.)

The electrostatic potential energy of this system of three point charges is the work needed to bring the charges from an infinite separation to the final positions shown in the diagram.



Express the work required to assemble this system of charges:

$$U = \frac{kq_1q_2}{r_{1,2}} + \frac{kq_1q_3}{r_{1,3}} + \frac{kq_2q_3}{r_{2,3}} = k\left(\frac{q_1q_2}{r_{1,2}} + \frac{q_1q_3}{r_{1,3}} + \frac{q_2q_3}{r_{2,3}}\right)$$

Find the distances $r_{1,2}$, $r_{1,3}$, and $r_{2,3}$:

$$r_{1,2} = 3\,\text{m}, r_{2,3} = 3\,\text{m}, \text{and}\, r_{1,3} = 6\,\text{m}$$

(a) Evaluate U for $q_1 = q_2 = q_3 = 2.00\ \mu$C:

$$U = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(\frac{(2.00\,\mu\text{C})(2.00\,\mu\text{C})}{3.00\,\text{m}} + \frac{(2.00\,\mu\text{C})(2.00\,\mu\text{C})}{6.00\,\text{m}} + \frac{(2.00\,\mu\text{C})(2.00\,\mu\text{C})}{3.00\,\text{m}}\right)$$

$$= \boxed{30.0\,\text{mJ}}$$

(b) Evaluate U for $q_1 = q_2 = 2.00\ \mu$C and $q_3 = -2.00\ \mu$C:

$$U = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(\frac{(2.00\,\mu\text{C})(2.00\,\mu\text{C})}{3.00\,\text{m}} + \frac{(2.00\,\mu\text{C})(-2.00\,\mu\text{C})}{6.00\,\text{m}} + \frac{(2.00\,\mu\text{C})(-2.00\,\mu\text{C})}{3.00\,\text{m}}\right)$$

$$= \boxed{-5.99\,\text{mJ}}$$

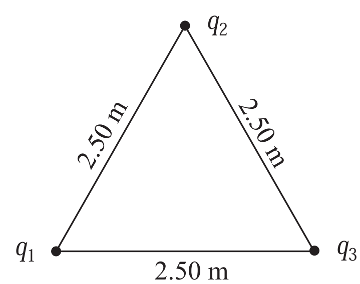
(c) Evaluate U for $q_1 = q_3 = 2.00\ \mu$C and $q_2 = -2.00\ \mu$C:

$$U = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(\frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{3.00\,\text{m}} + \frac{(2.00\ \mu\text{C})(2.00\ \mu\text{C})}{6.00\,\text{m}} + \frac{(-2.00\ \mu\text{C})(2.00\ \mu\text{C})}{3.00\,\text{m}}\right)$$

$$= \boxed{-18.0\,\text{mJ}}$$

66 • Point charges q_1, q_2, and q_3 are fixed at the vertices of an equilateral triangle whose sides are 2.50 m-long. Find the electrostatic potential energy of this system of charges for the following charge values:
(a) $q_1 = q_2 = q_3 = +4.20\ \mu$C, ($b$) $q_1 = q_2 = +4.20\ \mu$C and $q_3 = -4.20\ \mu$C; and (c) $q_1 = q_2 = -4.20\ \mu$C and $q_3 = +4.20\ \mu$C. (Assume the potential energy is zero when the charges are very far from each other.)

Picture the Problem The electrostatic potential energy of this system of three point charges is the work needed to bring the charges from an infinite separation to the final positions shown in the diagram.



Express the work required to assemble this system of charges:

$$U = \frac{kq_1q_2}{r_{1,2}} + \frac{kq_1q_3}{r_{1,3}} + \frac{kq_2q_3}{r_{2,3}} = k\left(\frac{q_1q_2}{r_{1,2}} + \frac{q_1q_3}{r_{1,3}} + \frac{q_2q_3}{r_{2,3}}\right)$$

Find the distances $r_{1,2}$, $r_{1,3}$, and $r_{2,3}$:

$$r_{1,2} = r_{2,3} = r_{1,3} = 2.50\,\text{m}$$

(a) Evaluate U for $q_1 = q_2 = q_3 = 4.20\ \mu$C:

$$U = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{(4.20\ \mu\text{C})(4.20\ \mu\text{C})}{2.50\,\text{m}} + \frac{(4.20\ \mu\text{C})(4.20\ \mu\text{C})}{2.50\,\text{m}} + \frac{(4.20\ \mu\text{C})(4.20\ \mu\text{C})}{2.50\,\text{m}}\right]$$

$$= \boxed{190\,\text{mJ}}$$

(*b*) Evaluate U for $q_1 = q_2 = 4.20\ \mu\text{C}$ and $q_3 = -4.20\ \mu\text{C}$:

$$U = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{(4.20\,\mu\text{C})(4.20\,\mu\text{C})}{2.50\,\text{m}} + \frac{(4.20\,\mu\text{C})(-4.20\,\mu\text{C})}{2.50\,\text{m}} + \frac{(4.20\,\mu\text{C})(-4.20\,\mu\text{C})}{2.50\,\text{m}}\right]$$

$$= \boxed{-63.4\,\text{mJ}}$$

(*c*) Evaluate U for $q_1 = q_2 = -4.20\ \mu\text{C}$ and $q_3 = +4.20\ \mu\text{C}$:

$$U = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{(-4.20\,\mu\text{C})(-4.20\,\mu\text{C})}{2.50\,\text{m}} + \frac{(-4.20\,\mu\text{C})(4.20\,\mu\text{C})}{2.50\,\text{m}} + \frac{(-4.20\,\mu\text{C})(4.20\,\mu\text{C})}{2.50\,\text{m}}\right]$$

$$= \boxed{-63.4\,\text{mJ}}$$

67 •• [SSM] (*a*) How much charge is on the surface of an isolated spherical conductor that has a 10.0-cm radius and is charged to 2.00 kV? (*b*)What is the electrostatic potential energy of this conductor? (Assume the potential is zero far from the sphere.)

Picture the Problem The potential of an isolated spherical conductor is given by $V = kQ/r$, where Q is its charge and r its radius, and its electrostatic potential energy by $U = \frac{1}{2}QV$. We can combine these relationships to find the sphere's electrostatic potential energy.

(*a*) The potential of the isolated spherical conductor at its surface is related to its radius:

$$V = \frac{kQ}{R} \Rightarrow Q = \frac{RV}{k}$$

where R is the radius of the spherical conductor.

Substitute numerical values and evaluate Q:

$$Q = \frac{(10.0\,\text{cm})(2.00\,\text{kV})}{8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}}$$

$$= 22.25\ \text{nC} = \boxed{22.3\,\text{nC}}$$

(*b*) Express the electrostatic potential energy of the isolated spherical conductor as a function of its charge Q and potential V:

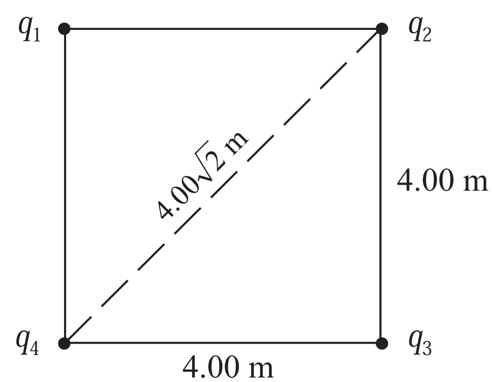
$$U = \tfrac{1}{2}QV$$

Substitute numerical values and evaluate U:

$$U = \tfrac{1}{2}(22.25\ \text{nC})(2.00\ \text{kV}) = \boxed{22.3\ \mu\text{J}}$$

68 ••• Four point charges, each having a charge with a magnitude of 2.00 μC, are at the corners of a square whose sides are 4.00 m-long. Find the electrostatic potential energy of this system under the following conditions: (*a*) all of the charges are negative, (*b*) three of the charges are positive and one of the charges is negative, and (*c*) the charges at two adjacent corners are positive and the other two charges are negative. (*d*) the charges at two opposite corners are positive and the other two charges are negative. (Assume the potential energy is zero when the point charges are very far from each other.)

Picture the Problem The electrostatic potential energy of this system of four point charges is the work needed to bring the charges from an infinite separation to the final positions shown in the diagram.



The work required to assemble this system of charges equals the potential energy of the assembled system:

$$U = \frac{kq_1q_2}{r_{1,2}} + \frac{kq_1q_3}{r_{1,3}} + \frac{kq_1q_4}{r_{1,4}} + \frac{kq_2q_3}{r_{2,3}} + \frac{kq_2q_4}{r_{2,4}} + \frac{kq_3q_4}{r_{3,4}}$$
$$= k\left(\frac{q_1q_2}{r_{1,2}} + \frac{q_1q_3}{r_{1,3}} + \frac{q_1q_4}{r_{1,4}} + \frac{q_2q_3}{r_{2,3}} + \frac{q_2q_4}{r_{2,4}} + \frac{q_3q_4}{r_{3,4}}\right)$$

Find the distances $r_{1,2}$, $r_{1,3}$, $r_{1,4}$, $r_{2,3}$, $r_{2,4}$, and $r_{3,4}$,:

$$r_{1,2} = r_{2,3} = r_{3,4} = r_{1,4} = 4.00\ \text{m}$$

and

$$r_{1,3} = r_{2,4} = 4.00\sqrt{2}\ \text{m}$$

(*a*) Evaluate U for $q_1 = q_2 = q_3 = q_4 = -2.00\ \mu\text{C}$:

$$U = \left(8.988\times10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{(-2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(-2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\sqrt{2}\ \text{m}} + \frac{(-2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(-2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(-2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\sqrt{2}\ \text{m}} + \frac{(-2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}}\right]$$

$$= \boxed{48.7\ \text{mJ}}$$

(*b*) Evaluate U for $q_1 = q_2 = q_3 = 2\ \mu\text{C}$ and $q_4 = -2.00\ \mu\text{C}$:

$$U = \left(8.988\times10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{(2.00\ \mu\text{C})(2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(2.00\ \mu\text{C})(2.00\ \mu\text{C})}{4.00\sqrt{2}\ \text{m}} + \frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(2.00\ \mu\text{C})(2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\sqrt{2}\ \text{m}} + \frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}}\right]$$

$$= \boxed{0}$$

(*c*) Let $q_1 = q_2 = 2.00\ \mu\text{C}$ and $q_3 = q_4 = -2.00\ \mu\text{C}$:

$$U = \left(8.988\times10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{(2.00\ \mu\text{C})(2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\sqrt{2}\ \text{m}} + \frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}} + \frac{(2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\sqrt{2}\ \text{m}} + \frac{(-2.00\ \mu\text{C})(-2.00\ \mu\text{C})}{4.00\ \text{m}}\right]$$

$$= \boxed{-12.7\ \text{mJ}}$$

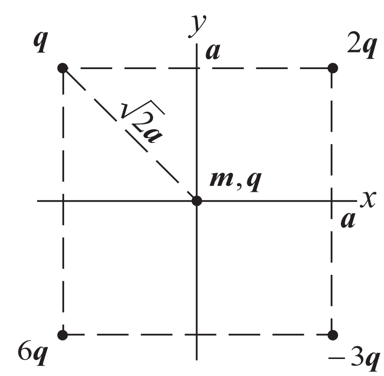
(d) Let $q_1 = q_3 = 2.00\ \mu\text{C}$ and $q_2 = q_4 = -2.00\ \mu\text{C}$:

$$U = \left(8.988\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left[\frac{(2.00\,\mu\text{C})(-2.00\,\mu\text{C})}{4.00\,\text{m}} + \frac{(2.00\,\mu\text{C})(2.00\,\mu\text{C})}{4.00\sqrt{2}\,\text{m}} + \frac{(2.00\,\mu\text{C})(-2.00\,\mu\text{C})}{4.00\,\text{m}} + \frac{(-2.00\,\mu\text{C})(2.00\,\mu\text{C})}{4.00\,\text{m}} + \frac{(-2.00\,\mu\text{C})(-2.00\,\mu\text{C})}{4.00\sqrt{2}\,\text{m}} + \frac{(2.00\,\mu\text{C})(-2.00\,\mu\text{C})}{4.00\,\text{m}}\right]$$

$$= \boxed{-23.2\,\text{mJ}}$$

69 •• [SSM] Four point charges are fixed at the corners of a square centered at the origin. The length of each side of the square is $2a$. The charges are located as follows: $+q$ is at $(-a, +a)$, $+2q$ is at $(+a, +a)$, $-3q$ is at $(+a, -a)$, and $+6q$ is at $(-a, -a)$. A fifth particle that has a mass m and a charge $+q$ is placed at the origin and released from rest. Find its speed when it is a very far from the origin.

Picture the Problem The diagram shows the four point charges fixed at the corners of the square and the fifth charged particle that is released from rest at the origin. We can use conservation of energy to relate the initial potential energy of the particle to its kinetic energy when it is at a great distance from the origin and the electrostatic potential at the origin to express U_i.



Use conservation of energy to relate the initial potential energy of the particle to its kinetic energy when it is at a great distance from the origin:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$K_f - U_i = 0$$

Express the initial potential energy of the particle to its charge and the electrostatic potential at the origin:

$$U_i = qV(0)$$

Substitute for K_f and U_i to obtain:

$$\tfrac{1}{2}mv^2 - qV(0) = 0 \Rightarrow v = \sqrt{\frac{2qV(0)}{m}}$$

Express the electrostatic potential at the origin:

$$V(0)=\frac{kq}{\sqrt{2}a}+\frac{2kq}{\sqrt{2}a}+\frac{-3kq}{\sqrt{2}a}+\frac{6kq}{\sqrt{2}a}=\frac{6kq}{\sqrt{2}a}$$

Substitute for $V(0)$ and simplify to obtain:

$$v=\sqrt{\frac{2q}{m}\left(\frac{6kq}{\sqrt{2}a}\right)}=\boxed{q\sqrt{\frac{6\sqrt{2}k}{ma}}}$$

70 •• Consider two point particles that each have charge $+e$, are at rest, and are separated by 1.50×10^{-15} m. (*a*) How much work was required to bring them together from a very large separation distance? (*b*) If they are released, how much kinetic energy will each have when they are separated by twice their separation at release? (*c*) The mass of each particle is 1.00 u (1.00 AMU). What speed will each have when they are very far from each other?

Picture the Problem (*a*) In the absence of other charged bodies, no work is required to bring the first proton from infinity to its initial position. We can use the work- energy theorem to find the work required to bring the second proton to a position 1.50×10^{-15} m away from the first proton. (*b*) and (*c*) We can apply conservation of mechanical energy to the two-proton system to find the kinetic energy of each proton when they are separated by twice their separation at release and when they are separated by a large distance.

(*a*) Apply the work-energy theorem to the second proton to obtain:

$$W_{\text{ext}}=\Delta K+\Delta U=0+\frac{ke^2}{r}=\frac{ke^2}{r}$$

Substitute numerical values and evaluate W_{ext}:

$$W_{\text{ext}}=\frac{\left(8.988\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.602\times10^{-19}\text{ C}\right)^2}{1.50\times10^{-15}\text{ m}}=1.538\times10^{-13}\text{ J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\text{ J}}=\boxed{960\,\text{keV}}$$

(*b*) Apply conservation of mechanical energy to the separating protons to obtain:

$$\Delta K+\Delta U=0\Rightarrow K_{\text{f}}-K_{\text{i}}+U_{\text{f}}-U_{\text{i}}=0$$

or, because $K_{\text{i}}=0$,

$$K_{\text{f}}+U_{\text{f}}-U_{\text{i}}=0$$

Substituting for U_{i} and U_{f} and simplifying yields:

$$K_{\text{f}}=U_{\text{i}}-U_{\text{f}}=\frac{ke^2}{r_{\text{i}}}-\frac{ke^2}{r_{\text{f}}}=\frac{ke^2}{r}-\frac{ke^2}{2r}=\frac{ke^2}{2r}$$

Remembering that K_f is the kinetic energy of both protons, substitute numerical values and evaluate $K_{\text{f, each proton}}$:

$$K_{\text{f, each proton}} = \frac{1}{2}\frac{\left(8.988\times10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.602\times10^{-19}\ \text{C}\right)^2}{2\left(1.50\times10^{-15}\ \text{m}\right)}$$
$$= 3.844\times10^{-14}\ \text{J}\times\frac{1\ \text{eV}}{1.602\times10^{-19}\ \text{J}}$$
$$= \boxed{240\ \text{keV}}$$

(*c*) Apply conservation of mechanical energy to the separating protons to obtain:

$$\Delta K + \Delta U = 0 \Rightarrow K_f - K_i + U_f - U_i = 0$$

or, because $K_i = U_f = 0$,

$$K_f - U_i = 0 \Rightarrow \tfrac{1}{2}m_p v_\infty^2 - U_i = 0$$

Solving for v_∞ yields:

$$v_\infty = \sqrt{\frac{2U_i}{m_p}}$$ where U_i is half the initial potential energy of the two-proton system.

Substitute numerical values and evaluate v_∞:

$$v_\infty = \sqrt{\frac{2\left(480\ \text{keV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)}{1.673\times10^{-27}\ \text{kg}}}$$
$$= \boxed{9.59\times10^{6}\ \text{m/s}}$$

71 ••• Consider an electron and a proton that are initially at rest and are separated by 2.00 nm. Neglecting any motion of the much more massive proton, what is the minimum (*a*) kinetic energy and (*b*) speed that the electron must be projected at so it reaches a point a distance of 12.0 nm from the proton? Assume the electron's velocity is directed radially away from the proton. (*c*) How far will the electron travel away from the proton if it has twice that initial kinetic energy?

Picture the Problem We can apply the conservation of mechanical energy to the electron-proton system to find the minimum initial kinetic energy (that is, the initial kinetic energy that corresponds to a final kinetic energy of zero) required in Part (*a*) and, in Part (*c*), to find how far the electron will travel away from the proton if it has twice the initial kinetic energy found in Part (*a*).

(*a*) Apply conservation of mechanical energy to the electron-stationary proton system with $K_f = 0$ to obtain:

$$\Delta K + \Delta U = 0 \Rightarrow -K_{i,\,min} + U_f - U_i = 0$$

Solving for $K_{i,\,min}$ and substituting for U_f and U_i yields:

$$K_{i,\,min} = U_f - U_i = -\frac{ke^2}{r_f} - \left(-\frac{ke^2}{r_i}\right)$$

or, simplifying further,

$$K_{i,\,min} = ke^2\left(\frac{1}{r_i} - \frac{1}{r_f}\right)$$

Substitute numerical values and evaluate $K_{i,\,min}$:

$$K_{i,\,min} = \left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.602\times10^{-19}\ \text{C}\right)^2\left(\frac{1}{2.00\ \text{nm}} - \frac{1}{12.0\ \text{nm}}\right)$$
$$= 9.611\times10^{-20}\ \text{J} = \boxed{9.61\times10^{-20}\ \text{J}}$$

(*b*) Relate the minimum initial kinetic energy of the electron to its initial speed:

$$K_{i,\,min} = \tfrac{1}{2}m_e v_i^2 \Rightarrow v_i = \sqrt{\frac{2K_{i,\,min}}{m_e}}$$

Substitute numerical values and evaluate v_i:

$$v_i = \sqrt{\frac{2\left(9.611\times10^{-20}\ \text{J}\right)}{9.109\times10^{-31}\ \text{kg}}} = \boxed{4.59\times10^5\ \text{m/s}}$$

(*c*) Apply conservation of mechanical energy to the electron- proton system to obtain:

$$\Delta K + \Delta U = 0 \Rightarrow K_f - K_i + U_f - U_i = 0$$

Assuming, as we did in Part (*a*), that $K_f = 0$ yields:

$$-2K_{i,\,min} + U_f - U_i = 0$$

Substituting for U_f and U_i yields:

$$-2K_{i,\,min} - \frac{ke^2}{r_f} + \frac{ke^2}{r_i} = 0$$

Solve for r_f to obtain:

$$r_f = \frac{r_i}{1 - \dfrac{2r_iK_{i,\,min}}{ke^2}}$$

Substituting numerical values and evaluating r_f yields a negative value; a result that is not physical and suggests that, contrary to our assumption, $K_f \neq 0$. To confirm that this is the case, assume that the electron escapes from the proton (it's final electrostatic potential will then be equal to zero) and find the initial kinetic energy required for this to occur.

If the electron is to escape the influence of the proton, its final electrostatic potential energy will be zero and:

$$K_{\text{i, escape}} = -U_i = -\left(-\frac{ke^2}{r_i}\right) = \frac{ke^2}{r_i}$$

Substitute numerical values and evaluate $K_{\text{i, escape}}$:

$$K_{\text{i, escape}} = \frac{\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.602\times10^{-19}\ \text{C}\right)^2}{2.00\ \text{nm}} = 1.15\times10^{-19}\ \text{J}$$

Because $2K_{\text{i, min}} > K_{\text{i, escape}}$, the electron escapes from the proton with residual kinetic energy.

General Problems

72 • A positive point charge equal to 4.80×10^{-19} C is separated from a negative point charge of the same magnitude by 6.40×10^{-10} m. What is the electric potential at a point 9.20×10^{-10} m from each of the two charges?

Picture the Problem Because the charges are point charges, we can use the expression for the Coulomb potential to find the field at any distance from them.

Using the expression for the potential due to a system of point charges, express the potential at the point 9.20×10^{-10} m from each of the two charges:

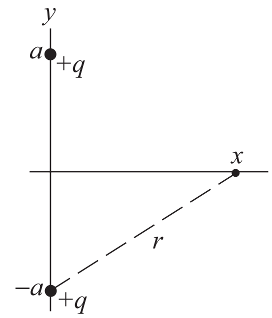
$$V = \frac{kq_+}{r} + \frac{kq_-}{r} = \frac{k}{r}\left(q_+ + q_-\right)$$

Because $q_+ = -q_-$:

$$V = \boxed{0}$$

73 • **[SSM]** Two positive point charges, each have a charge of $+q$, and are fixed on the y-axis at $y = +a$ and $y = -a$. (*a*) Find the electric potential at any point on the x-axis. (*b*) Use your result in Part (*a*) to find the electric field at any point on the x-axis.

Picture the Problem The potential V at any point on the x axis is the sum of the Coulomb potentials due to the two point charges. Once we have found V, we can use $\vec{E} = -(\partial V_x/\partial x)\hat{i}$ to find the electric field at any point on the x axis.



(*a*) Express the potential due to a system of point charges:

$$V = \sum_i \frac{kq_i}{r_i}$$

Substitute to obtain:

$$V(x) = V_{\text{charge at }+a} + V_{\text{charge at }-a} = \frac{kq}{\sqrt{x^2+a^2}} + \frac{kq}{\sqrt{x^2+a^2}} = \boxed{\frac{2kq}{\sqrt{x^2+a^2}}}$$

(*b*) The electric field at any point on the x axis is given by:

$$\vec{E}(x) = -\frac{\partial V_x}{\partial x}\hat{i} = -\frac{d}{dx}\left[\frac{2kq}{\sqrt{x^2+a^2}}\right]\hat{i} = \boxed{\frac{2kqx}{(x^2+a^2)^{3/2}}\hat{i}}$$

74 • If a conducting sphere is to be charged to a potential of 10.0 kV, what is the smallest possible radius of the sphere so that the electric field near the surface of the sphere will not exceed the dielectric strength of air?

Picture the Problem The radius of the sphere is related to the electric field and the potential at its surface. The dielectric strength of air is about 3 MV/m.

Relate the electric field at the surface of a conducting sphere to the potential at the surface of the sphere:

$$E_r = \frac{V(r)}{r} \Rightarrow r = \frac{V(r)}{E_r}$$

When E is a maximum, r is a minimum:

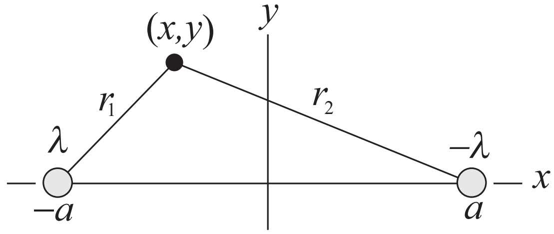
$$r_{\text{min}} = \frac{V(r)}{E_{\text{max}}}$$

Substitute numerical values and evaluate r_{min}:

$$r_{\text{min}} = \frac{10.0\,\text{kV}}{3\,\text{MV/m}} \approx \boxed{3\,\text{mm}}$$

75 •• **[SSM]** Two infinitely long parallel wires have a uniform charge per unit length λ and $-\lambda$ respectively. The wires are parallel with the z-axis. The positively charged wire intersects the x-axis at $x = -a$, and the negatively charged wire intersects the x-axis at $x = +a$. (a) Choose the origin as the reference point where the potential is zero, and express the potential at an arbitrary point (x, y) in the xy plane in terms of x, y, λ, and a. Use this expression to solve for the potential everywhere on the y axis. (b) Using a = 5.00 cm and λ = 5.00 nC/m, obtain the equation for the equipotential in the xy plane that passes through the point $x = \frac{1}{4}a$, $y = 0$. (c) Use a **spreadsheet** program to plot the equipotential found in part (b).

Picture the Problem The geometry of the wires is shown below. The potential at the point whose coordinates are (x, y) is the sum of the potentials due to the charge distributions on the wires.



(a) Express the potential at the point whose coordinates are (x, y):

$$V(x,y) = V_{\text{wire at }-a} + V_{\text{wire at }a}$$
$$= 2k\lambda \ln\left(\frac{r_{\text{ref}}}{r_1}\right) + 2k(-\lambda)\ln\left(\frac{r_{\text{ref}}}{r_2}\right)$$
$$= 2k\lambda\left[\ln\left(\frac{r_{\text{ref}}}{r_1}\right) - \ln\left(\frac{r_{\text{ref}}}{r_2}\right)\right]$$
$$= \frac{\lambda}{2\pi\epsilon_0}\ln\left(\frac{r_2}{r_1}\right)$$

where $V(0) = 0$.

Because $r_1 = \sqrt{(x+a)^2 + y^2}$ and $r_2 = \sqrt{(x-a)^2 + y^2}$:

$$V(x,y) = \boxed{\frac{\lambda}{2\pi\epsilon_0}\ln\left(\frac{\sqrt{(x-a)^2+y^2}}{\sqrt{(x+a)^2+y^2}}\right)}$$

On the y-axis, $x = 0$ and:

$$V(0,y) = \frac{\lambda}{2\pi\epsilon_0}\ln\left(\frac{\sqrt{a^2+y^2}}{\sqrt{a^2+y^2}}\right)$$
$$= \frac{\lambda}{2\pi\epsilon_0}\ln(1) = \boxed{0}$$

(b) Evaluate the potential at $\left(\frac{1}{4}a,0\right)=\left(1.25\,\text{cm},0\right)$:

$$V\left(\tfrac{1}{4}a,0\right)=\frac{\lambda}{2\pi\in_0}\ln\left(\frac{\sqrt{\left(\frac{1}{4}a-a\right)^2}}{\sqrt{\left(\frac{1}{4}a+a\right)^2}}\right)$$

$$=\frac{\lambda}{2\pi\in_0}\ln\left(\frac{3}{5}\right)$$

Equate $V(x,y)$ and $V\left(\frac{1}{4}a,0\right)$:

$$\frac{3}{5}=\frac{\sqrt{(x-5)^2+y^2}}{\sqrt{(x+5)^2+y^2}}$$

Solve for y to obtain:

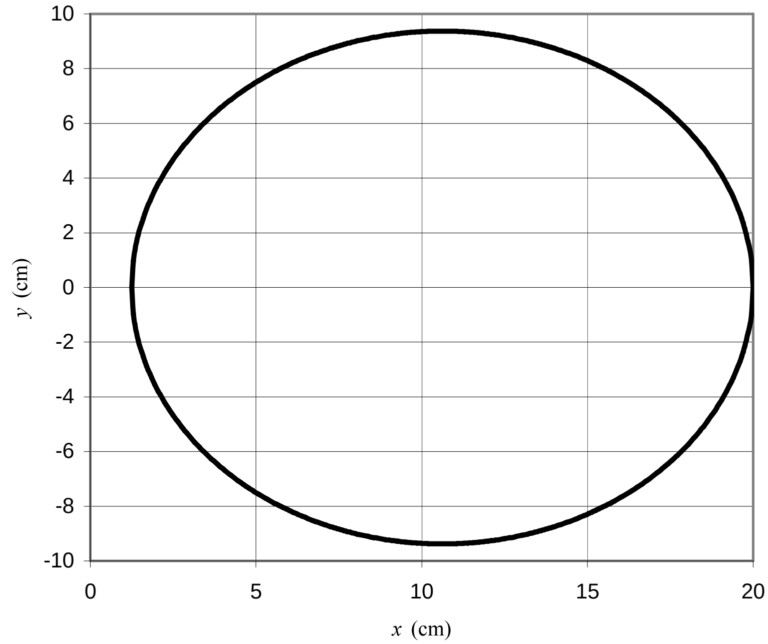
$$y=\boxed{\pm\sqrt{21.25x-x^2-25}}$$

(c) A spreadsheet program to plot $y=\pm\sqrt{21.25x-x^2-25}$ is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A2	1.25	$\frac{1}{4}a$
A3	A2 + 0.05	$x+\Delta x$
B2	SQRT(21.25*A2 – A2^2 – 25)	$y=\sqrt{21.25x-x^2-25}$
B4	–B2	$y=-\sqrt{21.25x-x^2-25}$

	A	B	C
1	x	y_{pos}	y_{neg}
2	1.25	0.00	0.00
3	1.30	0.97	–0.97
4	1.35	1.37	–1.37
5	1.40	1.67	–1.67
373	19.80	1.93	–1.93
374	19.85	1.67	–1.67
375	19.90	1.37	–1.37
376	19.95	0.97	–0.97

The following graph shows the equipotential curve in the xy plane for $V\left(\frac{1}{4}a,0\right)=\dfrac{\lambda}{2\pi\in_0}\ln\left(\dfrac{3}{5}\right)$.



76 •• The equipotential curve graphed in Problem 75 should be a circle. (*a*) Show mathematically that it is a circle. (*b*) The equipotential circle in the xy plane is the intersection of a three-dimensional equipotential surface and the xy plane. Describe the three-dimensional surface using one or two sentences.

Picture the Problem We can use the expression for the potential at any point in the xy plane to show that the equipotential curve is a circle.

(*a*) Equipotential surfaces must satisfy the condition:

$$V=\frac{\lambda}{2\pi\in_0}\ln\left(\frac{r_2}{r_1}\right)$$

Solving for r_2/r_1 yields:

$$\frac{r_2}{r_1}=e^{\frac{2\pi\in_0 V}{\lambda}}=C\ \text{ or }\ r_2=Cr_1$$

where C is a constant.

Substitute for r_1 and r_2 to obtain:

$$(x-a)^2+y^2=C^2\left[(x+a)^2+y^2\right]$$

Expand this expression, combine like terms, and simplify to obtain:

$$x^2+2a\frac{C^2+1}{C^2-1}x+y^2=-a^2$$

Complete the square by adding $\left[a^2\left(\frac{C^2+1}{C^2-1}\right)^2\right]$ to both sides of the equation:

$$x^2+2a\frac{C^2+1}{C^2-1}x+\left[a^2\left(\frac{C^2+1}{C^2-1}\right)^2\right]+y^2=\left[a^2\left(\frac{C^2+1}{C^2-1}\right)^2\right]-a^2=\frac{4a^2C^2}{\left(C^2-1\right)^2}$$

Letting $\alpha=2a\frac{C^2+1}{C^2-1}$ and $\beta=2a\frac{C}{C^2-1}$ yields:

$\boxed{(x+\alpha)^2+y^2=\beta^2,}$ the equation of circle in the xy plane with its center at $(-\alpha,0)$.

(b) The three-dimensional surfaces are cylinders whose axes are parallel to the wires and are in the $y = 0$ plane.

77 ••• The hydrogen atom in its ground state can be modeled as a positive point charge of magnitude $+e$ (the proton) surrounded by a negative charge distribution that has a charge density (the electron) that varies with the distance from the center of the proton r as: $\rho(r)=-\rho_0e^{-2r/a}$ (a result obtained from quantum mechanics), where a = 0.523 nm is the most probable distance of the electron from the proton. (a) Calculate the value of ρ_0 needed for the hydrogen atom to be neutral. (b) Calculate the electrostatic potential (relative to infinity) of this system as a function of the distance r from the proton.

Picture the Problem (a) Expressing the charge dq in a spherical shell of volume $4\pi r^2dr$ within a distance r of the proton and setting the integral of this expression equal to the charge of the electron will allow us to solve for the value of ρ_0 needed for charge neutrality. (b) The electrostatic potential of this system is the sum of the electrostatic potentials due to the proton and electron's charge density. The potential due to the proton is ke/r. We can use the given charge density to express the potential function due to the electron's charge distribution and then integrate this function to find the potential due to the electron.

(a) Express the charge dq in a spherical shell of volume $dV = 4\pi r^2dr$ at a distance r from the proton:

$$dq=\rho dV=\left(-\rho_0e^{-2r/a}\right)\left(4\pi r^2dr\right)=-4\pi\rho_0r^2e^{-2r/a}dr$$

Express the condition for charge neutrality:

$$e=-4\pi\rho_0\int_0^\infty r^2e^{-2r/a}dr$$

From a table of integrals we have:

$$\int x^2e^{bx}dx=\frac{e^{bx}}{b^3}\left(b^2x^2-2bx+2\right)$$

Using this result yields:

$$\int_0^\infty r^2 e^{-2r/a}\,dr = \frac{a^3}{4}$$

Substitute in the expression for e to obtain:

$$e = -4\pi\rho_0 \frac{a^3}{4} = -\pi\rho_0 a^3 \Rightarrow \rho_0 = -\frac{e}{\pi a^3}$$

Substitute numerical values and evaluate ρ_0:

$$\rho_0 = -\frac{1.602\times10^{-19}\ \text{C}}{\pi(0.523\ \text{nm})^3} = \boxed{-3.56\times10^{8}\ \text{C/m}^3}$$

(*b*) The electrostatic potential of this proton-electron system is the sum of the electrostatic potentials due to the proton and the electron's charge density:

$$V = V_1 + V_2 \qquad (1)$$

where

$$V_1 = \frac{ke}{r} + \frac{kQ_1}{r},$$

$$V_2 = \int_r^\infty \frac{k\rho(r')4\pi r'^2\,dr'}{r'} \qquad (2)$$

and

$$Q_1 = \int_0^r \rho(r')4\pi r'^2\,dr'$$

Substituting for $\rho(r')$ in the expression for Q_1 yields:

$$Q_1 = 4\pi\rho_0 \int_0^r r'^2 e^{-2r'/a}\,dr'$$

From a table of integrals we have:

$$\int x^2 e^{bx}\,dx = \frac{e^{bx}}{b^3}\left(b^2x^2 - 2bx + 2\right)$$

Using this result to evaluate $\int_0^r r'^2 e^{-2r'/a}\,dr'$ yields:

$$\begin{aligned}\int_0^r x^2 e^{-2x/a}\,dr' &= -\frac{a^3 e^{-2x/a}}{8}\left(\frac{4}{a^2}x^2 + 2\left(\frac{2}{a}\right)x + 2\right)\Bigg|_0^r \\ &= -\frac{a^3 e^{-2r/a}}{8}\left(\frac{4}{a^2}r^2 + \frac{4}{a}r + 2\right) - \left(-\frac{a^3}{8}(2)\right) \\ &= -\frac{a^3 e^{-2r/a}}{8}\left(\frac{4}{a^2}r^2 + \frac{4}{a}r + 2\right) + \frac{a^3}{4}\end{aligned}$$

and

$$Q_1 = 4\pi\rho_0\left[-\frac{a^3 e^{-2r/a}}{8}\left(\frac{4}{a^2}r^2 + \frac{4}{a}r + 2\right) + \frac{a^3}{4}\right]$$

Substituting for Q_1 in the expression for V_1 yields:

$$V_1 = \frac{ke}{r} + \frac{4\pi k\rho_0}{r}\left[-\frac{a^3e^{-2r/a}}{8}\left(\frac{4}{a^2}r^2 + \frac{4}{a}r + 2\right) + \frac{a^3}{4}\right]$$

Substitute for ρ_0 from Part (a) and simplify to obtain:

$$V_1 = \frac{ke}{r} + \frac{4\pi k\left(-\frac{e}{\pi a^3}\right)}{r}\left[-\frac{a^3e^{-2r/a}}{8}\left(\frac{4}{a^2}r^2 + \frac{4}{a}r + 2\right) + \frac{a^3}{4}\right]$$
$$= \frac{ke}{r}e^{-2r/a}\left(\frac{2}{a^2}r^2 + \frac{2}{a}r + 1\right)$$

Substituting for $\rho(r')$ in equation (2) and simplifying yields:

$$V_2 = \int_r^\infty \frac{k\rho_0 e^{-2r/a}4\pi r'^2\,dr'}{r'}$$
$$= 4\pi k\rho_0\int_r^\infty e^{-2r/a}r'\,dr'$$

From a table of integrals we have:

$$\int xe^{bx}dx = \frac{e^{bx}}{b^2}(bx-1)$$

Using this result to evaluate $\int_r^\infty e^{-2r/a}r'\,dr'$ yields:

$$\int_r^\infty e^{-2x/a}x\,dx = \frac{a^2}{4}e^{-2x/a}\left(\frac{2}{a}x+1\right)\Bigg|_r^\infty$$
$$= -\frac{a^2}{4}e^{-2x/a}\left(\frac{2}{a}r+1\right)$$

Substitute for $\int_r^\infty e^{-2r/a}r'\,dr'$ and ρ_0 in the expression for V_2 to obtain:

$$V_2 = 4\pi k\left(-\frac{e}{\pi a^3}\right)e^{-2x/a}\left[-\frac{a^2}{4}\left(\frac{2}{a}r+1\right)\right]$$
$$= ke\left(\frac{1}{a}\right)e^{-2r/a}\left(\frac{2}{a}r+1\right)$$

Substituting for V_1 and V_2 in equation (1) and simplifying yields:

$$V = \frac{ke}{r}e^{-2r/a}\left(\frac{2}{a^2}r^2 + \frac{2}{a}r + 1\right) + \frac{ke}{a}e^{-2r/a}\left(\frac{2}{a}r+1\right) = \boxed{ke\left(\frac{1}{a}+\frac{1}{r}\right)e^{-2r/a}}$$

78 •• Charge is supplied to the metal dome of a Van de Graaff generator by the belt at the rate of 200 μC/s when the potential difference between the belt and the dome is 1.25 MV. The dome transfers charge to the atmosphere at the same rate, so the 1.25 MV potential difference is maintained. What minimum power is needed to drive the moving belt and maintain the 1.25 MV potential difference?

Picture the Problem We can use the definition of power and the expression for the work done in moving a charge through a potential difference to find the minimum power needed to drive the moving belt.

Relate the power needed to drive the moving belt to the rate at which the generator is doing work:

$$P = \frac{dW}{dt}$$

Express the work done in moving a charge q through a potential difference ΔV:

$$W = q\Delta V$$

Substitute for W to obtain:

$$P = \frac{d}{dt}[q\Delta V] = \Delta V\frac{dq}{dt}$$

Substitute numerical values and evaluate P:

$$P = (1.25\,\text{MV})(200\,\mu\text{C/s}) = \boxed{250\text{ W}}$$

79 •• A positive point charge $+Q$ is located on the x axis at $x = -a$. (a) How much work is required to bring an identical point charge from infinity to the point on the x axis at $x = +a$? (b) With the two identical point charges in place at $x = -a$ and $x = +a$, how much work is required to bring a third point charge $-Q$ from infinity to the origin? (c) How much work is required to move the charge $-Q$ from the origin to the point on the x axis at $x = 2a$ along the semicircular path shown (Figure 23-35)?

Picture the Problem We can use $W_{q\to\text{final position}} = Q\Delta V_{i\to f}$ to find the work required to move these charges between the given points.

(a) Express the required work in terms of the charge being moved and the potential due to the charge at $x = +a$ and simplify to obtain:

$$W_{+Q\to+a} = Q\Delta V_{\infty\to+a} = Q[V(a) - V(\infty)]$$
$$= QV(a) = Q\left(\frac{kQ}{2a}\right) = \boxed{\frac{kQ^2}{2a}}$$

(*b*) Express the required work in terms of the charge being moved and the potentials due to the charges at $x = +a$ and $x = -a$ and simplify to obtain:

$$W_{-Q\to 0} = -Q\Delta V_{\infty\to 0} = -Q[V(0) - V(\infty)]$$
$$= -QV(0) = -Q\left[V_{\substack{\text{charge}\\ \text{at } -a}} + V_{\substack{\text{charge}\\ \text{at } +a}}\right]$$
$$= -Q\left(\frac{kQ}{a} + \frac{kQ}{a}\right) = \boxed{\frac{-2kQ^2}{a}}$$

(*c*) Express the required work in terms of the charge being moved and the potentials due to the charges at $x = +a$ and $x = -a$ and simplify to obtain:

$$W_{-Q\to 2a} = -Q\Delta V_{0\to 2a}$$
$$= -Q[V(2a) - V(0)]$$
$$= -Q\left[V_{\substack{\text{charge}\\ \text{at } -a}} + V_{\substack{\text{charge}\\ \text{at } +a}} - V(0)\right]$$
$$= -Q\left(\frac{kQ}{3a} + \frac{kQ}{a} - \frac{2kQ}{a}\right)$$
$$= \boxed{\frac{2kQ^2}{3a}}$$

80 •• A charge of +2.00 nC is uniformly distributed on a ring of radius 10.0 cm that lies in the $x = 0$ plane and is centered at the origin. A point charge of +1.00 nC is initially located on the x axis at $x = 50.0$ cm. Find the work required to move the point charge to the origin.

Picture the Problem Let q represent the charge being moved from $x = 50.0$ cm to the origin, Q the ring charge, and a the radius of the ring. We can use $W_{q\to\text{final position}} = q\Delta V_{i\to f}$, where V is the expression for the axial field due to a ring charge, to find the work required to move q from $x = 50.0$ cm to the origin.

Express the required work in terms of the charge being moved and the potential due to the ring charge at $x = 50.0$ cm and $x = 0$:

$$W = q\Delta V = q[V(0) - V(0.500\,\text{m})]$$

The potential on the axis of a uniformly charged ring is given by:

$$V(x) = \frac{kQ}{\sqrt{x^2 + a^2}}$$

At $x = 50.0$ cm:

$$V(0.500\,\text{m}) = \frac{kQ}{\sqrt{(0.500\,\text{m})^2 + a^2}}$$

At $x = 0$:

$$V(0) = \frac{kQ}{\sqrt{a^2}} = \frac{kQ}{a}$$

Substituting for $V(0)$ and $V(0.500\text{ m})$ yields:

$$W = q\left[\frac{kQ}{a} - \frac{kQ}{\sqrt{(0.500\text{ m})^2 + a^2}}\right] = kQq\left[\frac{1}{a} - \frac{1}{\sqrt{(0.500\text{ m})^2 + a^2}}\right]$$

Substitute numerical values and evaluate W:

$$W = \left(8.988\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(2.00\,\text{nC})(1.00\,\text{nC}) \times\left[\frac{1}{0.100\text{ m}} - \frac{1}{\sqrt{(0.500\text{ m})^2 + (0.100\text{ m})^2}}\right]$$

$$= 1.445\times10^{-7}\text{ J} = \boxed{1.4\times10^{-7}\text{ J}} = 1.445\times10^{-7}\text{ J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\text{ J}}$$

$$= \boxed{9.0\times10^{11}\text{ eV}}$$

81 •• Two metal spheres each have a radius of 10.0 cm. The centers of the two spheres are 50.0 cm apart. The spheres are initially neutral, but a charge Q is transferred from one sphere to the other, creating a potential difference between the spheres of 100 V. A proton is released from rest at the surface of the positively charged sphere and travels to the negatively charged sphere. (*a*) What is the proton′s kinetic energy just as it strikes the negatively charged sphere? (*b*) At what speed does it strike the sphere?

Picture the Problem The proton′s kinetic energy just as it strikes the negatively charged sphere is the product of its charge and the potential difference through which it has been accelerated. We can find the speed of the proton as it strikes the negatively charged sphere from its kinetic energy and, in turn, its kinetic energy from the potential difference through which it is accelerated.

(*a*) Apply the work-kinetic energy theorem to the proton to obtain:

$$W_{\text{net}} = \Delta K = K_{\text{f}} - K_{\text{i}}$$

or, because $K_{\text{i}} = 0$,

$$W_{\text{net}} = K_{\text{f}} = K_{\text{p}}$$

The net work done on the proton is given by:

$$W_{\text{net}} = q_{\text{p}}V$$

Equating W_{net} and K_{p} yields:

$$K_{\text{p}} = q_{\text{p}}V = e(100\text{ V}) = \boxed{100\text{ eV}}$$

(*b*) Use the definition of kinetic energy to express the speed of the proton when it strikes the negatively charged sphere:

$$K_p = \tfrac{1}{2}m_p v^2 \Rightarrow v = \sqrt{\frac{2K_p}{m_p}} = \sqrt{\frac{2\Delta V}{m_p}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{2\left(1.602\times10^{-19}\ \text{C}\right)\left(100\ \text{V}\right)}{1.673\times10^{-27}\ \text{kg}}} = \boxed{1.38\times10^{5}\ \text{m/s}}$$

82 •• (*a*) Using a **spreadsheet** program, graph $V(z)$ versus z for a uniformly charged ring in the $z = 0$ plane and centered at the origin. The potential on the z axis is given by $V(z) = kQ\big/\sqrt{a^2+z^2}$ (Equation 23-19). (*b*) Use your graph to estimate the points on the z axis where the electric field strength is greatest.

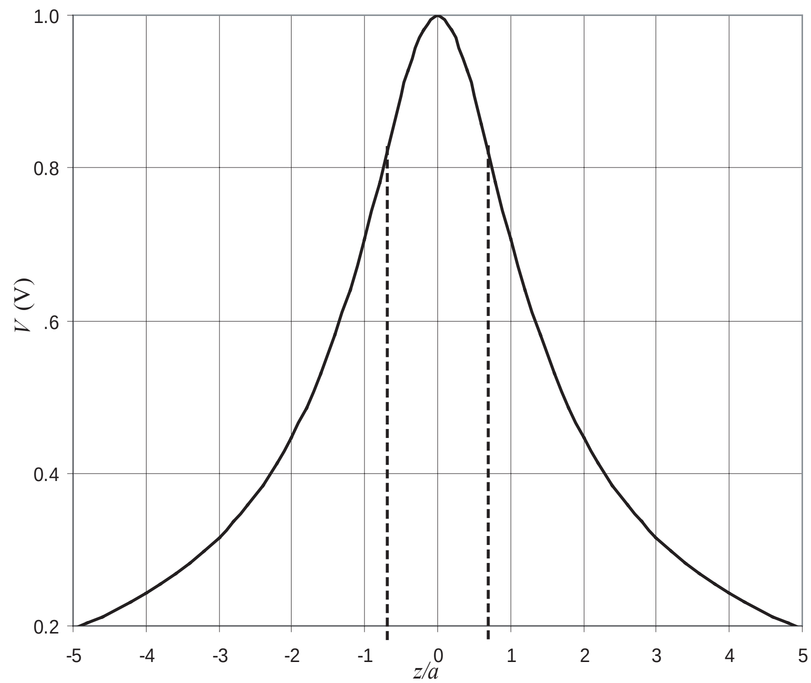
Picture the Problem (*b*) The electric field strength is greatest where the magnitude of the slope of the graph of electric potential is greatest.

(*a*) A spreadsheet solution is shown below for $kQ = a = 1$. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A4	A3 + 0.1	$z + \Delta z$
B3	1/(1+A3^2)^(1/2)	$\dfrac{kQ}{\sqrt{a^2+z^2}}$

	A	B
1		
2	z/a	$V(z/a)$
3	−5.0	0.196
4	−4.8	0.204
5	−4.6	0.212
6	−4.4	0.222
7	−4.2	0.232
8	−4.0	0.243
9	−3.8	0.254
49	4.2	0.232
50	4.4	0.222
51	4.6	0.212
52	4.8	0.204
53	5.0	0.196

The following graph, plotted using a spreadsheet program, shows V as a function of z/a:



Examining the graph we see that the magnitude of the slope is maximum at $z/a \approx \boxed{0.7}$ and at $z/a \approx \boxed{-0.7}$.

83 •• A spherical conductor of radius R_1 is charged to 20 kV. When it is connected by a long very-thin conducting wire to a second conducting sphere far away, its potential drops to 12 kV. What is the radius of the second sphere?

Picture the Problem Let R_2 be the radius of the second sphere and Q_1 and Q_2 the charges on the spheres when they have been connected by the wire. When the spheres are connected, the charge initially on the sphere of radius R_1 will redistribute until the spheres are at the same potential.

Express the common potential of the spheres when they are connected:

$$12\,\text{kV} = \frac{kQ_1}{R_1} \qquad (1)$$

and

$$12\,\text{kV} = \frac{kQ_2}{R_2} \qquad (2)$$

Express the potential of the first sphere before it is connected to the second sphere:

$$20\,\text{kV} = \frac{k(Q_1 + Q_2)}{R_1} \quad (3)$$

Solve equation (1) for Q_1:

$$Q_1 = \frac{(12\,\text{kV})R_1}{k}$$

Solve equation (2) for Q_2:

$$Q_2 = \frac{(12\,\text{kV})R_2}{k}$$

Substitute for Q_1 and Q_2 in equation (3) and simplify to obtain:

$$20\,\text{kV} = \frac{k\left(\frac{(12\,\text{kV})R_1}{k} + \frac{(12\,\text{kV})R_2}{k}\right)}{R_1} = 12\,\text{kV} + 12\,\text{kV}\left(\frac{R_2}{R_1}\right)$$

or

$$8 = 12\left(\frac{R_2}{R_1}\right) \Rightarrow R_2 = \boxed{\frac{2}{3}R_1}$$

84 •• A metal sphere centered at the origin has a surface charge density that has a magnitude of 24.6 nC/m^2 and a radius less than 2.00 m. A distance of 2.00 m from the origin, the electric potential is 500 V and the electric field strength is 250 V/m. (Assume the potential is zero very far from the sphere.) (*a*) What is the radius of the metal sphere? (*b*) What is the sign of the charge on the sphere? Explain your answer.

Picture the Problem We can use the definition of surface charge density to relate the radius R of the sphere to its charge Q and the potential function $V(r) = kQ/r$ to relate Q to the potential at r = 2.00 m.

(*a*) Use its definition, relate the surface charge density σ to the charge Q on the sphere and the radius R of the sphere:

$$\sigma = \frac{Q}{4\pi R^2} \Rightarrow R = \sqrt{\frac{Q}{4\pi\sigma}}$$

Relate the potential to the charge on the sphere:

$$V(r) = \frac{kQ}{r} \Rightarrow Q = \frac{rV(r)}{k}$$

Substitute for Q in the expression for R and simplify to obtain:

$$R=\sqrt{\frac{rV(r)}{4\pi k\sigma}}=\sqrt{\frac{4\pi\in_0 rV(r)}{4\pi\sigma}}=\sqrt{\frac{\in_0 rV(r)}{\sigma}}$$

Substitute numerical values and evaluate R:

$$R=\sqrt{\frac{(8.854\times10^{-12}\ \mathrm{C^2/N\cdot m^2})(2.00\ \mathrm{m})(500\ \mathrm{V})}{24.6\ \mathrm{nC/m^2}}}=\boxed{60.0\ \mathrm{cm}}$$

(b) The charge on the sphere is positive. The formula for the electric potential outside a uniformly charged spherical shell is $V=kQ/r$. If V is positive, then so is Q.

85 •• Along the central axis of a uniformly charged disk, at a point 0.60 m from the center of the disk, the potential is 80 V and the magnitude of the electric field is 80 V/m. At a distance of 1.5 m, the potential is 40 V and the magnitude of the electric field is 23.5 V/m. (Assume the potential is zero very far from the sphere.) Find the total charge on the disk.

Picture the Problem We can use the definition of surface charge density to relate the radius R of the disk to its charge Q and the potential function $V(r)=kQ/r$ to relate Q to the potential at r = 1.5 m.

Use its definition, relate the surface charge density σ to the charge Q on the disk and the radius R of the disk:

$$\sigma=\frac{Q}{\pi R^2}\Rightarrow Q=\pi\sigma R^2 \qquad (1)$$

Relate the potential at r to the charge on the disk:

$$V(r)=2\pi k\sigma\left(\sqrt{x^2+R^2}-x\right)$$

Substitute V(0.60 m) = 80 V:

$$80\ \mathrm{V}=2\pi k\sigma\left(\sqrt{(0.60\ \mathrm{m})^2+R^2}-0.60\ \mathrm{m}\right)$$

Substitute V(1.5 m) = 40 V:

$$40\ \mathrm{V}=2\pi k\sigma\left(\sqrt{(1.5\ \mathrm{m})^2+R^2}-1.5\ \mathrm{m}\right)$$

Divide the first of these equations by the second to obtain:

$$2=\frac{\sqrt{(0.60\ \mathrm{m})^2+R^2}-0.60\ \mathrm{m}}{\sqrt{(1.5\ \mathrm{m})^2+R^2}-1.5\ \mathrm{m}}$$

Solving for R yields:

$$R=0.80\ \mathrm{m}$$

Express the electric field on the axis of a disk charge:

$$E_x = 2\pi k\sigma\left(1-\frac{x}{\sqrt{x^2+R^2}}\right)$$

Solving for σ yields:

$$\sigma = \frac{E_x}{2\pi k\left(1-\frac{x}{\sqrt{x^2+R^2}}\right)} = \frac{2\in_0 E_x}{1-\frac{x}{\sqrt{x^2+R^2}}}$$

Substitute for σ in equation (1) to obtain:

$$Q = \frac{2\pi\in_0 R^2 E_x}{1-\frac{x}{\sqrt{x^2+R^2}}}$$

Substitute numerical values and evaluate Q:

$$Q = \frac{2\pi\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)(0.80\,\text{m})^2(23.5\,\text{V/m})}{1-\frac{1.5\,\text{m}}{\sqrt{(1.5\,\text{m})^2+(0.80\,\text{m})^2}}} = \boxed{7.1\,\text{nC}}$$

86 •• A radioactive ^{210}Po nucleus emits an α-particle that has a charge $+2e$. When the α-particle is a large distance from the nucleus it has a kinetic energy of 5.30 MeV. Assume that the α-particle had negligible kinetic energy as it left at the surface of the nucleus. The "daughter" (or residual) nucleus ^{206}Pb has a charge $+82e$. Determine the radius of the ^{206}Pb nucleus. (Neglect the radius of the α particle and assume the ^{206}Pb nucleus remains at rest.)

Picture the Problem We can use $U = kq_1q_2/r$ to relate the electrostatic potential energy of the particles to their separation.

Express the electrostatic potential energy of the two particles in terms of their charge and separation:

$$U = \frac{kq_1q_2}{r} \Rightarrow r = \frac{kq_1q_2}{U}$$

Substitute numerical values and evaluate r:

$$r = \frac{\left(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2\right)(2)(82)\left(1.602\times10^{-19}\,\text{C}\right)^2}{5.30\,\text{MeV}\times\frac{1.602\times10^{-19}\,\text{C}}{\text{eV}}} = \boxed{44.6\,\text{fm}}$$

87 ••• [SSM] Configuration *A* consists of two point particles; one particle has a charge of $+q$ and is on the x axis at $x = +d$ and the other particle has a charge of $-q$ and is at $x = -d$ (Figure 23-36*a*). (*a*) Assuming the potential is zero at large distances from these charged particles, show that the potential is also zero everywhere on the $x = 0$ plane. (*b*) Configuration *B* consists of a flat metal plate of infinite extent and a point particle located a distance *d* from the plate (Figure 23-36*b*) The point particle has a charge equal to $+q$ and the plate is grounded. (Grounding the plate forces its potential to equal zero.) Choose the line perpendicular to the plate and through the point charge as the x axis, and choose the origin at the surface of the plate nearest the particle. (These choices put the particle on the x axis at $x = +d$.) For configuration *B*, the electric potential is zero both at all points in the half-space $x \geq 0$ that are very far from the particle and at all points on the $x = 0$ plane—just as was the case for configuration *A*. (*c*) A theorem, called the *uniqueness theorem*, implies that throughout the half-space $x \geq 0$ the potential function *V*—and thus the electric field $\vec{E}$—for the two configurations are identical. Using this result, obtain the electric field $\vec{E}$ at every point in the $x = 0$ plane in the configuration *B*. (The uniqueness theorem tells us that in configuration *B* the electric field at each point in the $x = 0$ plane is the same as it is in configuration *A*.) Use this result to find the surface charge density σ at each point in the conducting plane (in configuration *B*).

Picture the Problem We can use the relationship between the potential and the electric field to show that this arrangement is equivalent to replacing the plane by a point charge of magnitude $-q$ located a distance *d* beneath the plane. In (*b*) we can first find the field at the plane surface and then use $\sigma = \epsilon_0 E$ to find the surface charge density. In (*c*) the work needed to move the charge to a point 2*d* away from the plane is the product of the potential difference between the points at distances 2*d* and 3*d* from $-q$ multiplied by the separation Δx of these points.

(*a*) The potential anywhere on the plane is 0 and the electric field is perpendicular to the plane in both configurations, so they must give the same potential everywhere in the *xy* plane. Also, because the net charge is zero, the potential at infinity is zero.

(*b*) The surface charge density is given by:

$$\sigma = \epsilon_0 E \qquad (1)$$

At any point on the plane, the electric field points in the negative x direction and has magnitude:

$$E=\frac{kq}{d^2+r^2}\cos\theta$$

where θ is the angle between the horizontal and a vector pointing from the positive charge to the point of interest on the xz plane and r is the distance along the plane from the origin (that is, directly to the left of the charge).

Because $\cos\theta=\dfrac{d}{\sqrt{d^2+r^2}}$:

$$E=\frac{kq}{d^2+r^2}\frac{d}{\sqrt{d^2+r^2}}=\frac{kqd}{\left(d^2+r^2\right)^{3/2}}$$
$$=\frac{qd}{4\pi\in_0\left(d^2+r^2\right)^{3/2}}$$

Substitute for E in equation (1) and simplify to obtain:

$$\sigma=\boxed{\frac{qd}{4\pi\left(d^2+r^2\right)^{3/2}}}$$

88 ••• A particle that has a mass m and a positive charge q is constrained to move along the x-axis. At $x = –L$ and $x = L$ are two ring charges of radius L (Figure 23-38). Each ring is centered on the x-axis and lies in a plane perpendicular to it. Each ring has a total positive charge Q uniformly distributed on it. (*a*) Obtain an expression for the potential $V(x)$ on the x axis due to the charge on the rings. (*b*) Show that $V(x)$ has a minimum at $x = 0$. (*c*) Show that for $|x|<<L$, the potential approaches the form $V(x) = V(0) + \alpha x^2$. (*d*) Use the result of Part (*c*) to derive an expression for the angular frequency of oscillation of the mass m if it is displaced slightly from the origin and released. (Assume the potential equals zero at points far from the rings.)

Picture the Problem We can express the potential due to the ring charges as the sum of the potentials due to each of the ring charges. To show that $V(x)$ is a minimum at $x = 0$, we must show that the first derivative of $V(x) = 0$ at $x = 0$ and that the second derivative is positive. In Part (*c*) we can use a Taylor expansion to show that, for $|x|<<L$, the potential approaches the form $V(x) = V(0) + \alpha x^2$. In Part (*d*) we can obtain the potential energy function from the potential function and, noting that it is quadratic in x, find the "spring" constant and the angular frequency of oscillation of the particle provided its displacement from its equilibrium position is small.

(a) Express the potential due to the ring charges as the sum of the potentials due to each of their charges:

$$V(x) = V_{\substack{\text{ring to}\\ \text{the left}}} + V_{\substack{\text{ring to}\\ \text{the right}}}$$

The potential for a ring of charge is:

$$V(x) = \frac{kQ}{\sqrt{x^2 + a^2}}$$

where a is the radius of the ring and Q is its charge.

For the ring to the left we have:

$$V_{\substack{\text{ring to}\\ \text{the left}}} = \frac{kQ}{\sqrt{(x+L)^2 + L^2}}$$

For the ring to the right we have:

$$V_{\substack{\text{ring to}\\ \text{the right}}} = \frac{kQ}{\sqrt{(x-L)^2 + L^2}}$$

Substitute for $V_{\substack{\text{ring to}\\ \text{the left}}}$ and $V_{\substack{\text{ring to}\\ \text{the right}}}$ to obtain:

$$V(x) = \boxed{\frac{kQ}{\sqrt{(x+L)^2 + L^2}} + \frac{kQ}{\sqrt{(x-L)^2 + L^2}}}$$

(b) Evaluate dV/dx to obtain:

$$\frac{dV}{dx} = kQ\left\{\frac{L-x}{\left[(L-x)^2 + L^2\right]^{3/2}} - \frac{L+x}{\left[(L+x)^2 + L^2\right]^{3/2}}\right\} = 0 \text{ for extrema}$$

Solving for x yields:

$$x = 0$$

Evaluate d^2V/dx^2 to obtain:

$$\frac{d^2V}{dx^2} = kQ\left\{\frac{3(L-x)^2}{\left[(L-x)^2 + L^2\right]^{5/2}} - \frac{1}{\left[(L-x)^2 + L^2\right]^{3/2}} + \frac{3(L+x)^2}{\left[(L+x)^2 + L^2\right]^{5/2}} - \frac{1}{\left[(L-x)^2 + L^2\right]^{3/2}}\right\}$$

Evaluating this expression for $x = 0$ yields:

$$\frac{d^2V(0)}{dx^2} = \frac{kQ}{2\sqrt{2}L^3} > 0$$

$$\Rightarrow \boxed{V(x) \text{ is a maximum at } x = 0.}$$

(*c*) The Taylor expansion of $V(x)$ is:

$$V(x) = V(0) + V'(0)x + \tfrac{1}{2}V''(0)x^2 + \text{higher order terms}$$

For $x << L$:

$$V(x) \approx V(0) + V'(0)x + \tfrac{1}{2}V''(0)x^2$$

Substitute our results from Parts (*a*) and (*b*) to obtain:

$$V(x) = \frac{\sqrt{2}kQ}{L} + (0)x + \tfrac{1}{2}\left(\frac{kQ}{2\sqrt{2}L^3}\right)x^2 = \frac{\sqrt{2}kQ}{L} + \frac{kQ}{4\sqrt{2}L^3}x^2$$

or

$$V(x) = \boxed{V(0) + \alpha x^2}$$

where

$$V(0) = \boxed{\frac{\sqrt{2}kQ}{L}} \text{ and } \alpha = \boxed{\frac{kQ}{4\sqrt{2}L^3}}$$

(*d*) Express the angular frequency of oscillation of a simple harmonic oscillator:

$$\omega = \sqrt{\frac{k'}{m}}$$

where k' is the restoring constant.

From our result for Part (*c*) and the definition of electric potential:

$$U(x) = qV(0) + \frac{1}{2}\left(\frac{kqQ}{2\sqrt{2}L^3}\right)x^2 = qV(0) + \tfrac{1}{2}k'x^2$$

where $k' = \dfrac{kqQ}{2\sqrt{2}L^3}$

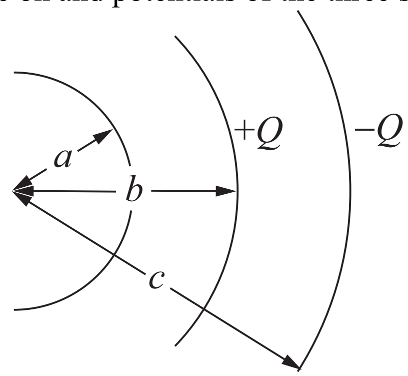
Substituting for k' in the expression for ω yields:

$$\omega = \boxed{\sqrt{\frac{kqQ}{2m\sqrt{2}L^3}}}$$

89 ••• Three concentric conducting thin spherical shells have radii a, b, and c so that $a < b < c$. Initially, the inner shell is uncharged, the middle shell has a positive charge $+Q$, and the outer shell has a charge $-Q$. (Assume the potential equals zero at points far from the shells.) (*a*) Find the electric potential of each of the three shells. (*b*) If the inner and outer shells are now connected by a conducting wire that is insulated as it passes through a small hole in the middle

shell, what is the electric potential of each of the three shells, and what is the final charge on each shell?

Picture the Problem The diagram shows part of the shells in a cross-sectional view under the conditions of Part (*a*) of the problem. We can use Gauss's law to find the electric field in the regions defined by the three surfaces and then find the electric potentials from the electric fields. In Part (*b*) we can use the redistributed charges to find the charge on and potentials of the three surfaces.



(*a*) Apply Gauss's law to a spherical Gaussian surface of radius $r \geq c$ to obtain:

$$E_r\left(4\pi r^2\right)=\frac{Q_{\text{enclosed}}}{\epsilon_0}=0$$

and $E_r = 0$ because the net charge enclosed by the Gaussian surface is zero.

Because $E_r(c) = 0$:

$$V(c)=\boxed{0}$$

Apply Gauss's law to a spherical Gaussian surface of radius $b < r < c$ to obtain:

$$E_r\left(4\pi r^2\right)=\frac{Q}{\epsilon_0}$$

and

$$E_r(b<r<c)=\frac{kQ}{r^2}$$

Use $E_r(b<r<c)$ to find the potential difference between c and b:

$$V(b)-V(c)=-kQ\int_c^b\frac{dr}{r^2}$$

$$=kQ\left(\frac{1}{b}-\frac{1}{c}\right)$$

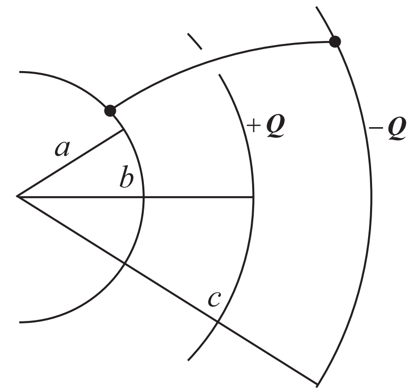
Because $V(c) = 0$:

$$V(b)=\boxed{kQ\left(\frac{1}{b}-\frac{1}{c}\right)}$$

The inner shell carries no charge, so the field between $r = a$ and $r = b$ is zero and:

$$V(a) = V(b) = \boxed{kQ\left(\frac{1}{b} - \frac{1}{c}\right)}$$

(b) When the inner and outer shells are connected their potentials become equal as a consequence of the redistribution of charge.



The charges on surfaces a and c are related according to:

$$Q_a + Q_c = -Q \tag{1}$$

Q_b does not change with the connection of the inner and outer shells:

$$Q_b = \boxed{Q}$$

Express the potentials of shells a and c:

$$V(a) = V(c) = \boxed{0}$$

In the region between the $r = a$ and $r = b$, the field is kQ_a/r^2 and the potential at $r = b$ is then:

$$V(b) = kQ_a\left(\frac{1}{b} - \frac{1}{a}\right) \tag{2}$$

The enclosed charge for $b < r < c$ is $Q_a + Q$, and by Gauss's law the field in this region is:

$$E_{b<r<c} = \frac{k(Q_a + Q)}{r^2}$$

Express the potential difference between b and c:

$$V(c) - V(b) = k(Q_a + Q)\left(\frac{1}{c} - \frac{1}{b}\right)$$
$$= -V(b)$$

because $V(c) = 0$.

Solve for $V(b)$ to obtain:

$$V(b) = k(Q_a + Q)\left(\frac{1}{b} - \frac{1}{c}\right) \tag{3}$$

Equate equations (2) and (3) and solve for Q_a to obtain:

$$Q_a = \boxed{-Q\frac{a(c-b)}{b(c-a)}} \qquad (4)$$

Substitute equation (4) in equation (1) and solve for Q_c to obtain:

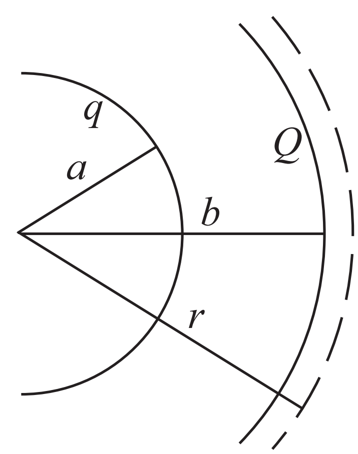
$$Q_c = \boxed{-Q\frac{c(b-a)}{b(c-a)}} \qquad (5)$$

Substitute equations (4) and (5) in equation (3) to obtain:

$$V(b) = \boxed{kQ\frac{(c-b)(b-a)}{b^2(c-a)}}$$

90 ••• Consider two concentric spherical thin metal shells of radii a and b, where $b > a$. The outer shell has a charge Q, but the inner shell is grounded. This means that the potential on the inner shell is the same as the potential at points far from the shells. Find the charge on the inner shell.

Picture the Problem The diagram shows a cross-sectional view of a portion of the concentric spherical shells. Let the charge on the inner shell be q. The dashed line represents a spherical Gaussian surface over which we can integrate $\vec{E}\cdot\hat{n}dA$ in order to find E_r for $r \geq b$. We can find $V(b)$ from the integral of E_r between $r = \infty$ and $r = b$. We can obtain a second expression for $V(b)$ by considering the potential difference between a and b and solving the two equations simultaneously for the charge q on the inner shell.



Apply Gauss's law to a spherical surface of radius $r \geq b$:

$$E_r\left(4\pi r^2\right) = \frac{Q+q}{\epsilon_0} \Rightarrow E_r = \frac{k(Q+q)}{r^2}$$

Use E_r to find $V(b)$:

$$V(b) = -k(Q+q)\int_{\infty}^{b}\frac{dr}{r^2} = \frac{k(Q+q)}{b}$$

We can also determine $V(b)$ by considering the potential difference between a, i.e., 0 and b:

$$V(b) = kq\left(\frac{1}{b} - \frac{1}{a}\right)$$

Equate these expressions for $V(b)$ to obtain:

$$\frac{k(Q+q)}{b} = ka\left(\frac{1}{b}-\frac{1}{a}\right) \Rightarrow q = \boxed{-\frac{a}{b}Q}$$

91 ••• [SSM] Show that the total work needed to assemble a uniformly charged sphere that has a total charge of Q and radius R is given by $3Q^2/(20\pi \in_0 R)$. Energy conservation tells us that this result is the same as the resulting electrostatic potential energy of the sphere. *Hint: Let ρ be the charge density of the sphere that has charge Q and radius R. Calculate the work dW to bring in charge dq from infinity to the surface of a uniformly charged sphere that has radius r (r < R) and charge density ρ. (No additional work is required to smear dq throughout a spherical shell of radius r, thickness dr, and charge density ρ. Why?)*

Picture the Problem We can use the hint to derive an expression for the electrostatic potential energy dU required to bring in a layer of charge of thickness dr and then integrate this expression from $r = 0$ to R to obtain an expression for the required work.

If we build up the sphere in layers, then at a given radius r the net charge on the sphere will be given by:

$$Q(r) = Q\left(\frac{r}{R}\right)^3$$

When the radius of the sphere is r, the potential relative to infinity is:

$$V(r) = \frac{Q(r)}{4\pi \in_0 r} = \frac{Q}{4\pi \in_0} \frac{r^2}{R^3}$$

Express the work dW required to bring in charge dQ from infinity to the surface of a uniformly charged sphere of radius r:

$$\begin{aligned} dW = dU &= V(r)dQ \\ &= \frac{Q}{4\pi \in_0}\frac{r^2}{R^3}\left(4\pi r^2 \frac{3Q}{4\pi R^3}dr\right) \\ &= \frac{3Q^2}{4\pi \in_0 R^6} r^4 dr \end{aligned}$$

Integrate dW from 0 to R to obtain:

$$\begin{aligned} W = U &= \frac{3Q^2}{4\pi \in_0 R^6}\int_0^R r^4 dr \\ &= \frac{3Q^2}{4\pi \in_0 R^6}\left[\frac{r^5}{5}\right]_0^R = \frac{3Q^2}{20\pi \in_0 R} \\ &= \boxed{\frac{3Q^2}{20\pi \in_0 R}} \end{aligned}$$

92 ••• (*a*) Use the result of Problem 91 to calculate the *classical electron radius*, the radius of a uniform sphere that has a charge $-e$ has and an electrostatic potential energy equal to the rest energy of the electron (5.11×10^5 eV). Comment

on the shortcomings of this model for the electron. (*b*) Repeat the calculation in Part (*a*) for a proton using its rest energy of 938 MeV. Experiments indicate the proton has an approximate radius of about 1.2×10^{-15} m. Is your result close to this value?

Picture the Problem We can equate the rest energy of an electron and the result of Problem 91 in order to obtain an expression that we can solve for the classical electron radius.

(*a*) From Problem 91 we have:

$$U = \frac{3e^2}{20\pi \in_0 R}$$

The rest energy of the electron is given by:

$$E_0 = m_0 c^2$$

Equate these energies to obtain:

$$\frac{3e^2}{20\pi \in_0 R} = m_0 c^2$$

Solving for R yields:

$$R = \frac{3e^2}{20\pi \in_0 m_0 c^2} \qquad (1)$$

Substitute numerical values and evaluate R:

$$R = \frac{3\left(1.602\times10^{-19}\ \text{C}\right)^2}{20\pi\left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(5.11\times10^5\ \text{eV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)} = \boxed{1.69\times10^{-15}\ \text{m}}$$

This model does not explain how the electron holds together against its own mutual repulsion.

(*b*) For a proton, equation (1) yields:

$$R = \frac{3\left(1.602\times10^{-19}\ \text{C}\right)^2}{20\pi\left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(938\ \text{MeV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)} = \boxed{9.21\times10^{-19}\ \text{m}}$$

This result is way too small to agree with the experimental value of 1.2×10^{-15} m.

93 ••• **[SSM]** (*a*) Consider a uniformly charged sphere that has radius R and charge Q and is composed of an incompressible fluid, such as water. If the sphere fissions (splits) into two halves of equal volume and equal charge, and if these halves stabilize into uniformly charged spheres, what is the radius R' of each? (*b*) Using the expression for potential energy shown in Problem 90,

calculate the change in the total electrostatic potential energy of the charged fluid. Assume that the spheres are separated by a large distance.

Picture the Problem Because the post-fission volumes of the fission products are equal, we can express the post-fission radii in terms of the radius of the pre-fission sphere.

(*a*) Relate the initial volume V of the uniformly charged sphere to the volumes V' of the fission products:

$$V = 2V'$$

Substitute for V and V':

$$\tfrac{4}{3}\pi R^3 = 2\left(\tfrac{4}{3}\pi R'^3\right)$$

Solving for R' yields:

$$R' = \frac{1}{\sqrt[3]{2}}R = \boxed{0.794R}$$

(*b*) Express the difference ΔE in the total electrostatic energy as a result of fissioning:

$$\Delta E = E' - E$$

From Problem 91 we have:

$$E = \frac{3Q^2}{20\pi \in_0 R}$$

After fissioning:

$$E' = 2\left(\frac{3Q'^2}{20\pi \in_0 R'}\right) = 2\left[\frac{3\left(\frac{1}{2}Q\right)^2}{20\pi \in_0 \frac{1}{\sqrt[3]{2}}R}\right]$$

$$= \frac{\sqrt[3]{2}}{2}\left(\frac{3Q^2}{20\pi \in_0 R}\right) = 0.630E$$

Substitute for E and E' to obtain:

$$\Delta E = 0.630E - E = \boxed{-0.370E}$$

94 ••• Problem 93 can be modified to be used as a very simple model for nuclear fission. When a ^{235}U nucleus absorbs a neutron, it can fission into the fragments ^{140}Xe, ^{94}Sr, and 2 neutrons. The ^{235}U has 92 protons, while ^{140}Xe has 54 protons and ^{94}Sr has 38 protons. Estimate the energy released during this fission process (in MeV), assuming that the mass density of the nucleus is constant and has a value of 4×10^{17} kg/m^3.

Picture the Problem We can use the definition of density to express the radius R of a nucleus as a function of its atomic mass N. We can then use the result derived in Problem 93 to express the electrostatic energies of the ^{235}U nucleus and the nuclei of the fission fragments ^{140}Xe and ^{94}Sr.

The energy released by this fission process is:

$$\Delta E = U_{^{235}\text{U}} - \left(U_{^{140}\text{Xe}} + U_{^{94}\text{Sr}}\right) \quad (1)$$

Express the mass of a nucleus in terms of its density and volume:

$$Nm = \tfrac{4}{3}\rho\pi R^3 \Rightarrow R = \sqrt[3]{\frac{3Nm}{4\pi\rho}}$$

where N is the nuclear number.

Substitute numerical values and evaluate R as a function of N:

$$R = \sqrt[3]{\frac{3\left(1.660\times10^{-27}\ \text{kg}\right)}{4\pi\left(4\times10^{17}\ \text{kg/m}^3\right)}}N^{1/3} = \left(9.97\times10^{-16}\ \text{m}\right)N^{1/3}$$

The 'radius' of the ^{235}U nucleus is therefore:

$$R_U = \left(9.97\times10^{-16}\ \text{m}\right)(235)^{1/3} = 6.15\times10^{-15}\ \text{m}$$

From Problem 91 we have:

$$U = \frac{3Q^2}{20\pi \in_0 R}$$

Substitute numerical values and evaluate the electrostatic energy of the ^{235}U nucleus:

$$U_{^{235}\text{U}} = \frac{3\left(92\times1.602\times10^{-19}\ \text{C}\right)^2}{20\pi\left(8.854\times10^{-12}\ \dfrac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(6.15\times10^{-15}\ \text{m}\right)}$$
$$= 1.90\times10^{-10}\ \text{J}\times\frac{1\text{eV}}{1.602\times10^{-19}\ \text{J/eV}} = 1189\,\text{MeV}$$

The radii of ^{140}Xe and ^{94}Sr are:

$$R_{^{149}\text{Xe}} = \left(9.97\times10^{-16}\ \text{m}\right)(140)^{1/3} = 5.177\times10^{-15}\ \text{m}$$

and

$$R_{^{94}\text{Sr}} = \left(9.97\times10^{-16}\ \text{m}\right)(94)^{1/3} = 4.533\times10^{-15}\ \text{m}$$

Proceed as above to find the electrostatic energy of the fission fragments ${}^{140}\text{Xe}$ and ${}^{94}\text{Sr}$:

$$U_{{}^{140}\text{Xe}} = \frac{3\left(54\times1.602\times10^{-19}\text{ C}\right)^2}{20\pi\left(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2\right)\left(5.18\times10^{-15}\text{ m}\right)}$$

$$= 7.791\times10^{-11}\text{ J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\text{ J/eV}} = 486\,\text{MeV}$$

and

$$U_{{}^{94}\text{Sr}} = \frac{3\left(38\times1.602\times10^{-19}\text{ C}\right)^2}{20\pi\left(8.854\times10^{-12}\text{ C}^2/\text{N}\cdot\text{m}^2\right)\left(4.53\times10^{-15}\text{ m}\right)}$$

$$= 4.412\times10^{-11}\text{ J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\text{ J/eV}} = 275\,\text{MeV}$$

Substitute for $U_{{}^{235}\text{U}}$, $U_{{}^{140}\text{Xe}}$, and $U_{{}^{94}\text{Sr}}$ in equation (1) and evaluate ΔE:

$$\Delta E = 1189\,\text{MeV} - \left(486\,\text{MeV} + 275\,\text{MeV}\right) \approx \boxed{428\,\text{MeV}}$$

Chapter 24
Capacitance

Conceptual Problems

1 • If the voltage across a parallel-plate capacitor is doubled, its capacitance (*a*) doubles (*b*) drops by half (*c*) remains the same.

Determine the Concept The capacitance of a parallel-plate capacitor is a function of the surface area of its plates, the separation of these plates, and the electrical properties of the matter between them. The capacitance is, therefore, independent of the voltage across the capacitor. $\boxed{(c)}$ is correct.

2 • If the charge on an isolated spherical conductor is doubled, its self-capacitance (*a*) doubles (*b*) drops by half (*c*) remains the same.

Determine the Concept The capacitance of an isolated spherical capacitor is given by $C = 4\pi \in_0 R$, where R is its radius. The capacitance is, therefore, independent of the charge of the capacitor. $\boxed{(c)}$ is correct.

3 • True or false: The electrostatic energy density is uniformly distributed in the region between the conductors of a cylindrical capacitor.

Determine the Concept False. The electrostatic energy density is not uniformly distributed the electric field strength is not uniformly distributed,

4 • If the distance between the plates of a charged and isolated parallel-plate capacitor is doubled, what is the ratio of the final stored energy to the initial stored energy?

Determine the Concept The energy stored in the electric field of a parallel-plate capacitor is related to the capacitance of the capacitor and the potential difference across the capacitor by $U = \frac{1}{2}QV$. Because the capacitor is isolated, Q is constant and U is directly proportional to V. Because, for a parallel-plate capacitor, $V = Ed$ and E is constant, U is directly proportional to d. Hence doubling the distance between the plates doubles the stored energy and the ratio of the initial stored energy to the final stored energy is $\boxed{2}$.

5 • **[SSM]** A parallel-plate capacitor is connected to a battery. The space between the two plates is empty. If the separation between the capacitor plates is tripled while the capacitor remains connected to the battery, what is the ratio of the final stored energy to the initial stored energy?

Determine the Concept The energy stored in a capacitor is given by $U = \frac{1}{2}QV$ and the capacitance of a parallel-plate capacitor by $C = \epsilon_0 A/d$. We can combine these relationships, using the definition of capacitance and the condition that the potential difference across the capacitor is constant, to express *U* as a function of *d*.

Express the energy stored in the capacitor:

$$U = \tfrac{1}{2}QV \qquad (1)$$

Use the definition of capacitance to express the charge of the capacitor:

$$Q = CV$$

Express the capacitance of a parallel-plate capacitor in terms of the separation *d* of its plates:

$$C = \frac{\epsilon_0 A}{d}$$

where *A* is the area of one plate.

Substituting for *Q* and *C* in equation (1) yields:

$$U = \frac{\epsilon_0 AV^2}{2d}$$

Because $U \propto \dfrac{1}{d}$, tripling the separation of the plates will reduce the energy stored in the capacitor to one-third its previous value. Hence the ratio of the final stored energy to the initial stored energy is $\boxed{1/3}$.

6 • If the capacitor of Problem 5 is disconnected from the battery before the separation between the plates is tripled, what is the ratio of the final stored energy to the initial stored energy?

Picture the Problem Let *V* represent the initial potential difference between the plates, *U* the energy stored in the capacitor initially, *d* the initial separation of the plates, and *V* ′, *U* ′, and *d* ′ these physical quantities when the plate separation has been tripled. We can use $U = \frac{1}{2}QV$ to relate the energy stored in the capacitor to the potential difference across it and $V = Ed$ to relate the potential difference to the separation of the plates.

Express the energy stored in the capacitor before the tripling of the separation of the plates:

$$U = \tfrac{1}{2}QV$$

Express the energy stored in the capacitor after the tripling of the separation of the plates:

$U' = \frac{1}{2}QV'$
because the charge on the plates does not change.

Express the ratio of U' to U and simplify to obtain:

$$\frac{U'}{U} = \frac{\frac{1}{2}QV'}{\frac{1}{2}QV} = \frac{V'}{V}$$

The potential differences across the capacitor plates before and after the plate separation, in terms of the electric field E between the plates, are given by:

$V = Ed$
and
$V' = Ed'$
because E depends solely on the charge on the plates and, as observed above, the charge does not change during the separation process.

Substituting for V and V' to obtain:

$$\frac{U'}{U} = \frac{Ed'}{Ed} = \frac{d'}{d}$$

For $d' = 3d$:

$\frac{U'}{U} = \frac{3d}{d} = 3 \Rightarrow$ The ratio of the final stored energy to the initial stored energy is $\boxed{3}$.

7 • True or false:

(*a*) The equivalent capacitance of two capacitors in parallel is always greater than the larger of the two capacitance values.
(*b*) The equivalent capacitance of two capacitors in series is always less than the least of the two capacitance values if the charges on the two plates that are connected by an otherwise isolated conductor sum to zero.

(*a*) True. The equivalent capacitance of two capacitors in parallel is the sum of the individual capacitances.

(*b*) True. The equivalent capacitance of two capacitors in series is the reciprocal of the sum of the reciprocals of the individual capacitances.

8 • Two uncharged capacitors have capacitances C_0 and $2C_0$, respectively, and are connected in series. This series combination is then connected across the terminals a battery. Which of the following is true?

(a) The capacitor $2C_0$ has twice the charge of the other capacitor.
(b) The voltage across each capacitor is the same.
(c) The energy stored by each capacitor is the same.
(d) The equivalent capacitance is $3C_0$.
(e) The equivalent capacitance is $2C_0/3$.

(a) False. Capacitors connected in series carry the same charge Q.

(b) False. The voltage V across a capacitor whose capacitance is C_0 is Q/C_0 and the voltage across the second capacitor is $Q/(2C_0)$.

(c) False. The energy stored in a capacitor is given by $\frac{1}{2}QV$.

(d) False. This would be the equivalent capacitance if they were connected in parallel.

(e) True. Taking the reciprocal of the sum of the reciprocals of C_0 and $2C_0$ yields $C_{eq} = 2C_0/3$.

9 • [SSM] A dielectric is inserted between the plates of a parallel-plate capacitor, completely filling the region between the plates. Air initially filled the region between the two plates. The capacitor was connected to a battery during the entire process. True or false:

(a) The capacitance value of the capacitor increases as the dielectric is inserted between the plates.
(b) The charge on the capacitor plates decreases as the dielectric is inserted between the plates.
(c) The electric field between the plates does not change as the dielectric is inserted between the plates.
(d) The energy storage of the capacitor decreases as the dielectric is inserted between the plates.

Determine the Concept The capacitance of the capacitor is given by $C = \dfrac{\kappa \in_0 A}{d}$, the charge on the capacitor is given by $Q = CV$, and the energy stored in the capacitor is given by $U = \frac{1}{2}CV^2$.

(a) True. As the dielectric material is inserted, κ increases from 1 (air) to its value for the given dielectric material.

(b) False. Q does not change. C increases and V decreases, but their product ($Q = CV$) is constant.

(c) False. Because $E = V/d$ and V decreases, E must decrease.

(d) False. The energy stored in the capacitor is given by $U = \frac{1}{2}CV^2$. Because V is constant and C increases, U increases.

10 •• Capacitors A and B (Figure 24-33) have identical plate areas and gap separations. The space between the plates of each capacitor is half-filled with a dielectric as shown. Which has the larger capacitance, capacitor A or capacitor B? Explain your answer.

Picture the Problem We can treat configuration A as two capacitors in parallel and configuration B as two capacitors in series. Finding the equivalent capacitance of each configuration and examining their ratio will allow us to decide whether A or B has the greater capacitance. In both cases, we'll let C_1 be the capacitance of the dielectric-filled capacitor and C_2 be the capacitance of the air capacitor.

In configuration A we have:

$$C_\mathrm{A} = C_1 + C_2$$

Express C_1 and C_2:

$$C_1 = \frac{\kappa \in_0 A_1}{d_1} = \frac{\kappa \in_0 \frac{1}{2} A}{d} = \frac{\kappa \in_0 A}{2d}$$

and

$$C_2 = \frac{\in_0 A_2}{d_2} = \frac{\in_0 \frac{1}{2} A}{d} = \frac{\in_0 A}{2d}$$

Substitute for C_1 and C_2 and simplify to obtain:

$$C_\mathrm{A} = \frac{\kappa \in_0 A}{2d} + \frac{\in_0 A}{2d} = \frac{\in_0 A}{2d}(\kappa + 1)$$

In configuration B we have:

$$\frac{1}{C_\mathrm{B}} = \frac{1}{C_1} + \frac{1}{C_2} \Rightarrow C_b = \frac{C_1 C_2}{C_1 + C_2}$$

Express C_1 and C_2:

$$C_1 = \frac{\in_0 A_1}{d_1} = \frac{\in_0 A}{\frac{1}{2} d} = \frac{2 \in_0 A}{d}$$

and

$$C_2 = \frac{\kappa \in_0 A_2}{d_2} = \frac{\kappa \in_0 A}{\frac{1}{2} d} = \frac{2\kappa \in_0 A}{d}$$

Substitute for C_1 and C_2 and simplify to obtain:

$$C_B = \frac{\left(\frac{2\in_0 A}{d}\right)\left(\frac{2\kappa\in_0 A}{d}\right)}{\frac{2\in_0 A}{d}+\frac{2\kappa\in_0 A}{d}} = \frac{\left(\frac{2\in_0 A}{d}\right)\left(\frac{2\kappa\in_0 A}{d}\right)}{\frac{2\in_0 A}{d}(\kappa+1)} = \frac{2\in_0 A}{d}\left(\frac{\kappa}{\kappa+1}\right)$$

Divide $\boldsymbol{C}_B$ by $\boldsymbol{C}_A$

$$\frac{C_B}{C_A} = \frac{\frac{2\in_0 A}{d}\left(\frac{\kappa}{\kappa+1}\right)}{\frac{\in_0 A}{2d}(\kappa+1)} = \frac{4\kappa}{(\kappa+1)^2}$$

Because $\frac{4\kappa}{(\kappa+1)^2} < 1$ for $\kappa > 1$:

$$\boxed{C_A > C_B}$$

11 •• [SSM] (*a*) Two identical capacitors are connected in parallel. This combination is then connected across the terminals of a battery. How does the total energy stored in the parallel combination of the two capacitors compare to the total energy stored if just one of the capacitors were connected across the terminals of the same battery? (*b*) Two identical capacitors that have been discharged are connected in series. This combination is then connected across the terminals of a battery. How does the total energy stored in the series combination of the two capacitors compare to the total energy stored if just one of the capacitors were connected across the terminals of the same battery?

Picture the Problem The energy stored in a capacitor whose capacitance is C and across which there is a potential difference V is given by $U = \frac{1}{2}CV^2$. Let C_0 represent the capacitance of the each of the two identical capacitors.

(*a*) The energy stored in the parallel system is given by:

$$U_{\text{parallel}} = \tfrac{1}{2}C_{\text{eq}}V^2$$

When the capacitors are connected in parallel, their equivalent capacitance is:

$$C_{\text{parallel}} = C_0 + C_0 = 2C_0$$

Substituting for C_{eq} and simplifying yields:

$$U_{\text{parallel}} = \tfrac{1}{2}(2C_0)V^2 = C_0V^2 \qquad (1)$$

If just one capacitor is connected to the same battery the stored energy is:

$$U_{1\,\text{capacitor}} = \tfrac{1}{2}C_0V^2 \qquad (2)$$

Dividing equation (1) by equation (2) and simplifying yields:

$$\frac{U_{\text{parallel}}}{U_{1\,\text{capacitor}}} = \frac{C_0V^2}{\tfrac{1}{2}C_0V^2} = 2$$

or

$$U_{\text{parallel}} = \boxed{2U_{1\,\text{capacitor}}}$$

(*b*) The energy stored in the series system is given by:

$$U_{\text{series}} = \tfrac{1}{2}C_{eq}V^2$$

When the capacitors are connected in series, their equivalent capacitance is:

$$C_{\text{series}} = \tfrac{1}{2}C_0$$

Substituting for C_{eq} and simplifying yields:

$$U_{\text{series}} = \tfrac{1}{2}\left(\tfrac{1}{2}C_0\right)V^2 = \tfrac{1}{4}C_0V^2 \quad (3)$$

Dividing equation (3) by equation (2) and simplifying yields:

$$\frac{U_{\text{series}}}{U_{1\,\text{capacitor}}} = \frac{\tfrac{1}{4}C_0V^2}{\tfrac{1}{2}C_0V^2} = \tfrac{1}{2}$$

or

$$U_{\text{series}} = \boxed{\tfrac{1}{2}U_{1\,\text{capacitor}}}$$

12 •• Two identical capacitors that have been discharged are connected in series across the terminals of a 100-V battery. When only one of the capacitors is connected across the terminals of this battery, the energy stored is U_0. What is the total energy stored in the two capacitors when the series combination is connected to the battery? (*a*) $4U_0$, (*b*) $2U_0$, (*c*) U_0, (*d*) $U_0/2$, (*e*) $U_0/4$

Picture the Problem We can use the expression $U = \tfrac{1}{2}CV^2$ to express the ratio of the energy stored in the single capacitor and in the identical-capacitors-in-series combination.

Express the energy stored in the capacitors when they are connected to the 100-V battery:

$$U = \tfrac{1}{2}C_{eq}V^2$$

Express the equivalent capacitance of the two identical capacitors connected in series:

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C} + \frac{1}{C} \Rightarrow C_{\text{eq}} = \tfrac{1}{2}C$$

Substitute for C_{eq} to obtain:

$$U = \tfrac{1}{2}\left(\tfrac{1}{2}C\right)V^2 = \tfrac{1}{4}CV^2$$

Express the energy stored in one capacitor when it is connected to the 100-V battery:

$$U_0 = \tfrac{1}{2}CV^2$$

Express the ratio of U to U_0:

$$\frac{U}{U_0} = \frac{\tfrac{1}{4}CV^2}{\tfrac{1}{2}CV^2} = \frac{1}{2} \Rightarrow U = \tfrac{1}{2}U_0$$

$\boxed{(d)}$ is correct.

Estimation and Approximation

13 •• [SSM] Disconnect the coaxial cable from a television or other device and estimate the diameter of the inner conductor and the diameter of the shield. Assume a plausible value (see Table 24–1) for the dielectric constant of the dielectric separating the two conductors and estimate the capacitance per unit length of the cable.

Picture the Problem The outer diameter of a "typical" coaxial cable is about 5 mm, while the inner diameter is about 1 mm. From Table 24-1 we see that a reasonable range of values for κ is 3-5. We can use the expression for the capacitance of a cylindrical capacitor to estimate the capacitance per unit length of a coaxial cable.

The capacitance of a cylindrical dielectric-filled capacitor is given by:

$$C = \frac{2\pi\kappa \in_0 L}{\ln\left(\frac{R_2}{R_1}\right)}$$

where L is the length of the capacitor, R_1 is the radius of the inner conductor, and R_2 is the radius of the second (outer) conductor.

Divide both sides by L to obtain an expression for the capacitance per unit length of the cable:

$$\frac{C}{L} = \frac{2\pi\kappa \in_0}{\ln\left(\frac{R_2}{R_1}\right)} = \frac{\kappa}{2k\ln\left(\frac{R_2}{R_1}\right)}$$

If $\kappa = 3$:

$$\frac{C}{L} = \frac{3}{2\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\ln\left(\dfrac{2.5\,\text{mm}}{0.5\,\text{mm}}\right)} \approx 0.1\,\text{nF/m}$$

If $\kappa = 5$:

$$\frac{C}{L} = \frac{5}{2\left(8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2\right)\ln\left(\dfrac{2.5\,\text{mm}}{0.5\,\text{mm}}\right)} \approx 0.2\,\text{nF/m}$$

A reasonable range of values for C/L, corresponding to $3 \le \kappa \le 5$, is:

$$\boxed{0.1\,\text{nF/m} \le \frac{C}{L} \le 0.2\,\text{nF/m}}$$

14 •• You are part of an engineering research team that is designing a pulsed nitrogen laser. To create the high-energy densities needed to operate such a laser, the electrical discharge from a high-voltage capacitor is used. Typically, the energy requirement per pulse (i.e., per discharge) is 100 J. Estimate the capacitance required if the discharge is to creates a spark across a gap of about 1.0 cm. Assume that the dielectric breakdown of nitrogen is the same as the value for normal air.

Picture the Problem The energy stored in a capacitor is given by $U = \frac{1}{2}CV^2$.

Relate the energy stored in a capacitor to its capacitance and the potential difference across it:

$$U = \tfrac{1}{2}CV^2 \Rightarrow C = \frac{2U}{V^2}$$

The potential difference across the spark gap is related to the width of the gap d and the electric field E in the gap:

$$V = Ed$$

Substitute for V in the expression for C to obtain:

$$C = \frac{2U}{E^2d^2}$$

Substitute numerical values and evaluate C:

$$C = \frac{2(100\,\text{J})}{\left(3\times10^{6}\ \text{V/m}\right)^2(1.0\,\text{cm})^2} = \boxed{22\,\mu\text{F}}$$

15 •• [SSM] Estimate the capacitance of the Leyden jar shown in the Figure 24-34. The figure of a man is one-tenth the height of an average man.

Picture the Problem Modeling the Leyden jar as a parallel-plate capacitor, we can use the equation for the capacitance of a dielectric-filled parallel-plate capacitor that relates its capacitance to the area A of its plates and their separation (the thickness of the glass) d to estimate the capacitance of the jar. See Table 24-1 for the dielectric constants of various materials.

The capacitance of a dielectric-filled parallel-plate capacitor is given by:

$$C = \frac{\kappa \in_0 A}{d}$$

where κ is the dielectric constant.

Let the plate area be the sum of the area of the lateral surface of the jar and its base:

$$A = A_{\substack{\text{lateral}\\\text{area}}} + A_{\text{base}} = 2\pi Rh + \pi R^2$$

where h is the height of the jar and R is its inside radius.

Substitute for A and simplify to obtain:

$$C = \frac{\kappa \in_0 \left(2\pi Rh + \pi R^2\right)}{d} = \frac{\pi\kappa \in_0 R(2h + R)}{d}$$

If the glass of the Leyden jar is Bakelite of thickness 2.0 mm and the radius and height of the jar are 4.0 cm and 40 cm, respectively, then:

$$C = \frac{\pi(4.9)(4.0\text{ cm})\left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left[2(40\text{ cm}) + 4.0\text{ cm}\right]}{2.0\text{ mm}} = \boxed{2.3\text{ nF}}$$

Capacitance

16 • An isolated conducting sphere that has a 10.0 cm radius has an electric potential of 2.00 kV (the potential far from the sphere is zero). (*a*) How much charge is on the sphere? (*b*) What is the self-capacitance of the sphere? (*c*) By how much does the self-capacitance change if the sphere's electric potential is increased to 6.00 kV?

Picture the Problem The charge on the spherical conductor is related to its radius and potential according to $V = kQ/r$ and we can use the definition of capacitance to find the self-capacitance of the sphere.

(*a*) Relate the potential *V* of the spherical conductor to the charge on it and to its radius:

$$V = \frac{kQ}{r} \Rightarrow Q = \frac{rV}{k}$$

Substitute numerical values and evaluate *Q*:

$$Q = \frac{(10.0\,\text{cm})(2.00\,\text{kV})}{8.988\times 10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}} = 22.252\text{ nC}$$

$$= \boxed{22.3\,\text{nC}}$$

(*b*) Use the definition of capacitance to relate the self-capacitance of the sphere to its charge and potential:

$$C = \frac{Q}{V} = \frac{22.252\,\text{nC}}{2.00\,\text{kV}} = \boxed{11.1\,\text{pF}}$$

(*c*) It doesn't. The self-capacitance of a sphere is a function of its radius.

17 • The charge on one plate of a capacitor is +30.0 μC and the charge on the other plate is –30.0 μC. The potential difference between the plates is 400 V. What is the capacitance of the capacitor?

Picture the Problem We can use its definition to find the capacitance of this capacitor.

Use the definition of capacitance to obtain:

$$C = \frac{Q}{V} = \frac{30.0\,\mu\text{C}}{400\,\text{V}} = \boxed{75.0\,\text{nF}}$$

18 •• Two isolated conducting spheres of equal radius *R* have charges +*Q* and –*Q*, respectively. Their centers are separated by a distance *d* that is large compared to their radius. Estimate the capacitance of this unusual capacitor.

Picture the Problem Let the separation of the spheres be *d* and their radii be *R*. Outside the two spheres the electric field is approximately the field due to point charges of +*Q* and −*Q*, each located at the centers of spheres, separated by distance *d*. We can derive an expression for the potential at the surface of each sphere and then use the potential difference between the spheres and the definition of capacitance and to estimate the capacitance of the two-sphere system.

The capacitance of the two-sphere system is given by:

$$C = \frac{Q}{\Delta V}$$

where ΔV is the potential difference between the spheres.

The potential at any point outside the two spheres is:

$$V=\frac{k(+Q)}{r_1}+\frac{k(-Q)}{r_2}$$

where r_1 and r_2 are the distances from the given point to the centers of the spheres.

For a point on the surface of the sphere with charge $+Q$:

$r_1=R$ and $r_2=d+\delta$
where $|\delta|<R$

Substitute to obtain:

$$V_{+Q}=\frac{k(+Q)}{R}+\frac{k(-Q)}{d+\delta}$$

For $\delta \ll d$:

$$V_{+Q}=\frac{kQ}{R}-\frac{kQ}{d}$$

and

$$V_{-Q}=-\frac{kQ}{R}+\frac{kQ}{d}$$

The potential difference between the spheres is:

$$\begin{aligned}\Delta V&=V_Q-V_{-Q}\\&=\frac{kQ}{R}-\frac{kQ}{d}-\left(\frac{-kQ}{R}+\frac{kQ}{d}\right)\\&=2kQ\left(\frac{1}{R}-\frac{1}{d}\right)\end{aligned}$$

Substitute for ΔV in the expression for C to obtain:

$$\begin{aligned}C&=\frac{Q}{2kQ\left(\frac{1}{R}-\frac{1}{d}\right)}=\frac{2\pi\in_0}{\left(\frac{1}{R}-\frac{1}{d}\right)}\\&=\frac{2\pi\in_0 R}{1-\frac{R}{d}}\end{aligned}$$

For $d \gg R$:

$$C=\boxed{2\pi\in_0 R}$$

The Storage of Electrical Energy

19 • **[SSM]** (*a*) The potential difference between the plates of a 3.00-μF capacitor is 100 V. How much energy is stored in the capacitor? (*b*) How much additional energy is required to increase the potential difference between the plates from 100 V to 200 V?

Picture the Problem Of the three equivalent expressions for the energy stored in a charged capacitor, the one that relates U to C and V is $U = \frac{1}{2}CV^2$.

(*a*) Express the energy stored in the capacitor as a function of C and V:

$$U = \tfrac{1}{2}CV^2$$

Substitute numerical values and evaluate U:

$$U = \tfrac{1}{2}(3.00\,\mu\text{F})(100\,\text{V})^2 = \boxed{15.0\,\text{mJ}}$$

(*b*) Express the additional energy required as the difference between the energy stored in the capacitor at 200 V and the energy stored at 100 V:

$$\begin{aligned}\Delta U &= U(200\,\text{V}) - U(100\,\text{V})\\ &= \tfrac{1}{2}(3.00\,\mu\text{F})(200\,\text{V})^2 - 15.0\,\text{mJ}\\ &= \boxed{45.0\,\text{mJ}}\end{aligned}$$

20 • The charges on the plates of a 10-μF capacitor are ±4.0 μC. (*a*) How much energy is stored in the capacitor? (*b*) If charge is transferred until the charges on the plates are equal to ±2.0 μC, how much stored energy remains?

Picture the Problem Of the three equivalent expressions for the energy stored in a charged capacitor, the one that relates U to Q and C is $U = \frac{1}{2}\frac{Q^2}{C}$.

(*a*) Express the energy stored in the capacitor as a function of C and Q:

$$U = \frac{1}{2}\frac{Q^2}{C}$$

Substitute numerical values and evaluate U:

$$U = \frac{1}{2}\frac{(4.0\,\mu\text{C})^2}{10\,\mu\text{F}} = \boxed{0.80\,\mu\text{J}}$$

(*b*) Express the energy remaining when half the charge is removed:

$$U\left(\tfrac{1}{2}Q\right) = \frac{1}{2}\frac{(2.0\,\mu\text{C})^2}{10\,\mu\text{F}} = \boxed{0.20\,\mu\text{J}}$$

21 • (*a*) Find the energy stored in a 20.0-nF capacitor when to the charges on the plates are ±5.00 μC. (*b*) How much additional energy is stored if charges are increased from ±5.00 μC to ±10.0 μC?

Picture the Problem Of the three equivalent expressions for the energy stored in a charged capacitor, the one that relates U to Q and C is $U = \frac{1}{2}\frac{Q^2}{C}$.

(*a*) Express the energy stored in the capacitor as a function of *C* and *Q*:

$$U = \frac{1}{2}\frac{Q^2}{C}$$

Substitute numerical values and evaluate *U*:

$$U(5.00\,\mu\text{C}) = \frac{1}{2}\frac{(5.00\,\mu\text{C})^2}{20.0\,\text{nF}} = \boxed{0.625\,\text{mJ}}$$

(*b*) Express the additional energy required as the difference between the energy stored in the capacitor when its charge is 5 μC and when its charge is 10 μC:

$$\begin{aligned}\Delta U &= U(10.0\,\mu\text{C}) - U(5.00\,\mu\text{C})\\ &= \frac{1}{2}\frac{(10.0\,\mu\text{C})^2}{20.0\,\text{nF}} - 0.625\,\text{mJ}\\ &= 2.50\,\text{mJ} - 0.625\,\text{mJ} = \boxed{1.88\,\text{mJ}}\end{aligned}$$

22 • What is the maximum electric energy density in a region containing dry air at standard conditions?

Picture the Problem The energy per unit volume in an electric field varies with the square of the electric field according to $u = \frac{1}{2}\epsilon_0 E^2$. Under standard conditions, dielectric breakdown occurs at approximately E = 3.0 MV/m.

Express the energy per unit volume in an electric field:

$$u = \tfrac{1}{2}\epsilon_0 E^2$$

Substitute numerical values and evaluate *u*:

$$\begin{aligned}u &= \tfrac{1}{2}\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(3.0\,\frac{\text{MV}}{\text{m}}\right)^2\\ &\approx \boxed{40\,\text{J/m}^3}\end{aligned}$$

23 •• **[SSM]** An air-gap parallel-plate capacitor that has a plate area of 2.00 m^2 and a separation of 1.00 mm is charged to 100 V. (*a*) What is the electric field between the plates? (*b*) What is the electric energy density between the plates? (*c*) Find the total energy by multiplying your answer from Part (*b*) by the volume between the plates. (*d*) Determine the capacitance of this arrangement. (*e*) Calculate the total energy from $U = \frac{1}{2}CV^2$, and compare your answer with your result from Part (*c*).

Picture the Problem Knowing the potential difference between the plates, we can use $E = V/d$ to find the electric field between them. The energy per unit volume is given by $u = \frac{1}{2}\epsilon_0 E^2$ and we can find the capacitance of the parallel-plate capacitor using $C = \epsilon_0 A/d$.

(*a*) Express the electric field between the plates in terms of their separation and the potential difference between them:

$$E=\frac{V}{d}=\frac{100\,\text{V}}{1.00\,\text{mm}}=\boxed{100\,\text{kV/m}}$$

(*b*) Express the energy per unit volume in an electric field:

$$u=\tfrac{1}{2}\in_0 E^2$$

Substitute numerical values and evaluate *u*:

$$u=\tfrac{1}{2}\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)(100\,\text{kV/m})^2$$
$$=44.27\ \text{mJ/m}^3=\boxed{44.3\,\text{mJ/m}^3}$$

(*c*) The total energy is given by:

$$U=uV=uAd$$
$$=\left(44.27\,\text{mJ/m}^3\right)\left(2.00\,\text{m}^2\right)(1.00\,\text{mm})$$
$$=\boxed{88.5\,\mu J}$$

(*d*) The capacitance of a parallel-plate capacitor is given by:

$$C=\frac{\in_0 A}{d}$$

Substitute numerical values and evaluate *C*:

$$C=\frac{\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(2.00\,\text{m}^2\right)}{1.00\,\text{mm}}$$
$$=17.71\,\text{nF}=\boxed{17.7\,\text{nF}}$$

(*e*) The total energy is given by:

$$U=\tfrac{1}{2}CV^2$$

Substitute numerical values and evaluate *U*:

$$U=\tfrac{1}{2}(17.71\text{nF})(100\,\text{V})^2$$
$$=\boxed{88.5\,\mu\text{J, in agreement with }(c).}$$

24 •• A solid metal sphere has radius of 10.0 cm and a concentric metal spherical shell has an inside radius of 10.5 cm. The solid sphere has a charge 5.00 nC. (*a*) Estimate the energy stored in the electric field in the region between the spheres. *Hint: You can treat the spheres essentially as parallel flat slabs separated by 0.5 cm*. (*b*) Estimate the capacitance of this two-sphere system. (*c*) Estimate the total energy stored in the electric field from $\tfrac{1}{2}Q^2/C$ and compare it to your answer in Part (*a*).

Picture the Problem The total energy stored in the electric field is the product of the energy density in the space between the spheres and the volume of this space.

(*a*) The total energy U stored in the electric field is given by:

$U = uV$
where u is the energy density and V is the volume between the spheres.

The energy density of the field is:

$u = \frac{1}{2} \in_0 E^2$
where E is the field between the spheres.

The volume between the spheres is approximately:

$V \approx 4\pi r_1^2 (r_2 - r_1)$

Substitute for u and V to obtain:

$$U = 2\pi \in_0 E^2 r_1^2 (r_2 - r_1) \qquad (1)$$

The magnitude of the electric field between the concentric spheres is the sum of the electric fields due to each charge distribution:

$E = E_Q + E_{-Q}$

Because the two surfaces are so close together, the electric field between them is approximately the sum of the fields due to two plane charge distributions:

$$E = \frac{\sigma_Q}{2 \in_0} + \frac{\sigma_{-Q}}{2 \in_0} = \frac{\sigma_Q}{\in_0}$$

Substitute for σ_Q to obtain:

$$E \approx \frac{Q}{4\pi r_1^2 \in_0}$$

Substitute for E in equation (1) and simplify:

$$U = 2\pi \in_0 \left(\frac{Q}{4\pi r_1^2 \in_0}\right)^2 r_1^2 (r_2 - r_1) = \frac{Q^2}{8\pi \in_0} \frac{r_2 - r_1}{r_1^2}$$

Substitute numerical values and evaluate U:

$$U = \frac{(5.00\,\text{nC})^2 (10.5\,\text{cm} - 10.0\,\text{cm})}{8\pi \left(8.854 \times 10^{-12} \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)(10.0\,\text{cm})^2} = 56.2 \times 10^{-9}\ \text{J} = \boxed{0.06\,\mu\text{J}}$$

(*b*) The capacitance of the two-sphere system is given by:

$$C = \frac{Q}{\Delta V}$$

where ΔV is the potential difference between the two spheres.

The electric potentials at the surfaces of the spheres are:

$$V_1 = \frac{Q}{4\pi \in_0 r_1} \text{ and } V_2 = \frac{Q}{4\pi \in_0 r_2}$$

Substitute for ΔV and simplify to obtain:

$$C = \frac{Q}{\frac{Q}{4\pi \in_0 r_1} - \frac{Q}{4\pi \in_0 r_2}} = 4\pi \in_0 \frac{r_1 r_2}{r_2 - r_1}$$

Substitute numerical values and evaluate C:

$$C = 4\pi\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\frac{(10.0\,\text{cm})(10.5\,\text{cm})}{10.5\,\text{cm}-10.0\,\text{cm}} = 0.2337\text{ nF} = \boxed{0.2\,\text{nF}}$$

(*c*) Use $\frac{1}{2}Q^2/C$ to find the total energy stored in the electric field between the spheres:

$$U = \frac{1}{2}\left[\frac{(5.00\,\text{nC})^2}{0.2337\,\text{nF}}\right] = \boxed{0.05\,\mu\text{J}}$$

a result that agrees to within 5% with the exact result obtained in (*a*).

25 •• A parallel-plate capacitor has plates of area 500 cm^2 and is connected across the terminals of a battery. After some time has passed, the capacitor is disconnected from the battery. When the plates are then moved 0.40 cm farther apart, the charge on each plate remains constant but the potential difference between the plates increases by 100 V. (*a*) What is the magnitude of the charge on each plate? (*b*) Do you expect the energy stored in the capacitor to increase, decrease, or remain constant as the plates are moved this way? Explain your answer. (*c*) Support your answer to Part (*b*), by determining the change in stored energy in the capacitor due to the movement of the plates.

Picture the Problem (*a*) We can relate the charge Q on the positive plate of the capacitor to the charge density of the plate σ using its definition. The charge density, in turn, is related to the electric field between the plates according to $\sigma = \in_0 E$ and the electric field can be found from $E = \Delta V/\Delta d$. We can use $\Delta U = \frac{1}{2}Q\Delta V$ in Part (*c*) to find the increase in the energy stored due to the movement of the plates.

(*a*) Express the charge Q on the positive plate of the capacitor in terms of the plate's charge density σ and surface area A:

$$Q = \sigma A$$

Relate σ to the electric field E between the plates of the capacitor:

$$\sigma = \epsilon_0 E$$

Express E in terms of the change in V as the plates are separated a distance Δd:

$$E = \frac{\Delta V}{\Delta d}$$

Substitute for σ and E to obtain:

$$Q = \epsilon_0 EA = \epsilon_0 A\frac{\Delta V}{\Delta d}$$

Substitute numerical values and evaluate Q:

$$Q = \left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)\left(500\,\text{cm}^2\right)\frac{100\,\text{V}}{0.40\,\text{cm}} = 11.1\,\text{nC} = \boxed{11\,\text{nC}}$$

(*b*) Because work has to be done to pull the plates farther apart, you would expect the energy stored in the capacitor to increase.

(*c*) Express the change in the electrostatic energy in terms of the change in the potential difference:

$$\Delta U = \tfrac{1}{2}Q\Delta V$$

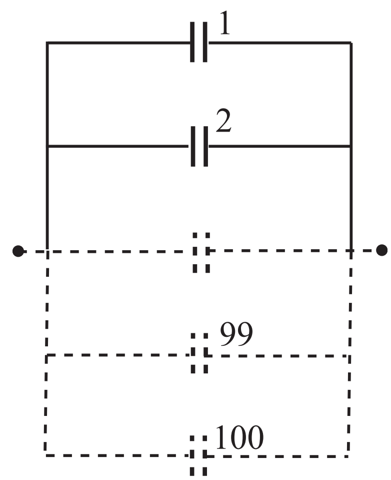
Substitute numerical values and evaluate ΔU:

$$\Delta U = \tfrac{1}{2}(11.1\,\text{nC})(100\,\text{V}) = \boxed{0.55\,\mu\text{J}}$$

Combinations of Capacitors

26 • (*a*) How many 1.00-μF capacitors connected in parallel would it take to store a total charge of 1.00 mC if the potential difference of across each capacitor is 10.0 V? Diagram the parallel combination. (*b*) What would be the potential difference across this parallel combination? (*c*) If the capacitors in Part (*a*) are discharged, connected in series, and then energized until the potential difference across each is equal to 10.0 V, find the charge on each capacitor and the potential difference across the connection.

Picture the Problem We can apply the properties of capacitors connected in parallel to determine the number of 1.00-μF capacitors connected in parallel it would take to store a total charge of 1.00 mC with a potential difference of 10.0 V across each capacitor. Knowing that the capacitors are connected in parallel (Parts (*a*) and (*b*)) we determine the potential difference across the combination. In Part (*c*) we can use our knowledge of how potential differences add in a series circuit to find the potential difference across the combination and the definition of capacitance to find the charge on each capacitor.



(*a*) Express the number of capacitors n in terms of the charge q on each and the total charge Q:

$$n = \frac{Q}{q}$$

Relate the charge q on one capacitor to its capacitance C and the potential difference across it:

$$q = CV$$

Substitute for q to obtain:

$$n = \frac{Q}{CV}$$

Substitute numerical values and evaluate n:

$$n = \frac{1.00\,\text{mC}}{(1.00\,\mu\text{F})(10.0\,\text{V})} = \boxed{100}$$

(*b*) Because the capacitors are connected in parallel the potential difference across the combination is the same as the potential difference across each of them:

$$V_{\substack{\text{parallel}\\ \text{combination}}} = V = \boxed{10.0\,\text{V}}$$

(*c*) With the capacitors connected in series, the potential difference across the combination will be the sum of the potential differences across the 100 capacitors:

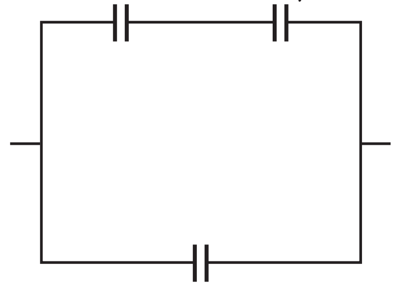
$$V_{\substack{\text{series}\\\text{combination}}} = 100(10.0\,\text{V})$$
$$= \boxed{1.00\,\text{kV}}$$

Use the definition of capacitance to find the charge on each capacitor:

$$q = CV = (1\,\mu\text{F})(10\,\text{V}) = \boxed{10.0\,\mu\text{C}}$$

27 • A 3.00-μF capacitor and a 6.00-μF capacitor are discharged and then connected in series, and the series combination is then connected in parallel with an 8.00-μF capacitor. Diagram this combination. What is the equivalent capacitance of this combination?

Picture the Problem The capacitor array is shown in the diagram. We can find the equivalent capacitance of this combination by first finding the equivalent capacitance of the 3.00-μF and 6.00-μF capacitors in series and then the equivalent capacitance of this capacitor with the 8.00-μF capacitor in parallel.



Express the equivalent capacitance for the 3.00-μF and 6.00-μF capacitors in series:

$$\frac{1}{C_{3+6}} = \frac{1}{3.00\,\mu\text{F}} + \frac{1}{6.00\,\mu\text{F}}$$

Solve for C_{3+6}:

$$C_{3+6} = 2.00\,\mu\text{F}$$

Find the equivalent capacitance of a 2.00-μF capacitor in parallel with an 8.00-μF capacitor:

$$C_{2+8} = 2.00\,\mu\text{F} + 8.00\,\mu\text{F} = \boxed{10.00\,\mu\text{F}}$$

28 • Three capacitors are connected in a triangle as shown in Figure 24-35. Find an expression for the equivalent capacitance between points *a* and *c* in terms of the three capacitance values.

Picture the Problem Because we're interested in the equivalent capacitance across terminals *a* and *c*, we need to recognize that capacitors C_1 and C_3 are in series with each other and in parallel with capacitor C_2.

Find the equivalent capacitance of C_1 and C_3 in series:

$$\frac{1}{C_{1+3}} = \frac{1}{C_1} + \frac{1}{C_3} \Rightarrow C_{1+3} = \frac{C_1C_3}{C_1 + C_3}$$

Find the equivalent capacitance of C_{1+3} and C_2 in parallel:

$$C_{\text{eq}} = C_2 + C_{1+3} = \boxed{C_2 + \frac{C_1C_3}{C_1 + C_3}}$$

29 •• A 10.0-μF capacitor and a 20.0-μF capacitor are connected in parallel across the terminals of a 6.00-V battery. (*a*) What is the equivalent capacitance of this combination? (*b*) What is the potential difference across each capacitor? (*c*) Find the charge on each capacitor. (*d*) Find the energy stored in each capacitor.

Picture the Problem Because the capacitors are connected in parallel we can add their capacitances to find the equivalent capacitance of the combination. Also, because they are in parallel, they have a common potential difference across them. We can use the definition of capacitance to find the charge on each capacitor.

(*a*) Find the equivalent capacitance of the two capacitors in parallel:

$$C_{\text{eq}} = 10.0\,\mu\text{F} + 20.0\,\mu\text{F} = \boxed{30.0\,\mu\text{F}}$$

(*b*) Because capacitors in parallel have a common potential difference across them:

$$V = V_{10} = V_{20} = \boxed{6.00\,\text{V}}$$

(*c*) Use the definition of capacitance to find the charge on each capacitor:

$$Q_{10} = C_{10}V = (10.0\,\mu\text{F})(6.00\,\text{V}) = \boxed{60.0\,\mu\text{C}}$$

and

$$Q_{20} = C_{20}V = (20.0\,\mu\text{F})(6.00\,\text{V}) = \boxed{120\,\mu\text{C}}$$

(*d*) Use $\boldsymbol{U} = \frac{1}{2}\boldsymbol{QV}$ to find the energy stored in each capacitor:

$$U_{10} = \tfrac{1}{2}Q_{10}V_{10} = \tfrac{1}{2}(60.0\,\mu\text{C})(6.00\text{ V}) = \boxed{180\,\mu\text{J}}$$

and

$$U_{20} = \tfrac{1}{2}Q_{20}V_{20} = \tfrac{1}{2}(120.0\,\mu\text{C})(6.00\text{ V}) = \boxed{360\,\mu\text{J}}$$

30 •• A 10.0-μF capacitor and a 20.0-μF capacitor are connected in parallel across the terminals of a 6.00-V battery. (*a*) What is the equivalent capacitance of this combination? (*b*) What is the potential difference across each capacitor?

(*c*) Find the charge on each capacitor. (*d*) Find the energy stored in each capacitor.

Picture the Problem We can use the properties of capacitors in series to find the equivalent capacitance and the charge on each capacitor. We can then apply the definition of capacitance to find the potential difference across each capacitor.

(*a*) Because the capacitors are connected in series they have equal charges:

$$Q_{10} = Q_{20} = C_{eq}V$$

Express the equivalent capacitance of the two capacitors in series:

$$\frac{1}{C_{eq}} = \frac{1}{10.0\,\mu\text{F}} + \frac{1}{20.0\,\mu\text{F}}$$

Solve for C_{eq} to obtain:

$$C_{eq} = \frac{(10.0\,\mu\text{F})(20.0\,\mu\text{F})}{10.0\,\mu\text{F} + 20.0\,\mu\text{F}} = \boxed{6.67\,\mu\text{F}}$$

(*b*) Because the capacitors are in series, they have the same charge. Substitute numerical values to obtain:

$$Q_{10} = Q_{20} = (6.67\,\mu\text{F})(6.00\,\text{V}) = \boxed{40.0\,\mu\text{C}}$$

(*c*) Apply the definition of capacitance to find the potential difference across each capacitor:

$$V_{10} = \frac{Q_{10}}{C_{10}} = \frac{40.0\,\mu\text{C}}{10.0\,\mu\text{F}} = \boxed{4.00\,\text{V}}$$

and

$$V_{20} = \frac{Q_{20}}{C_{20}} = \frac{40.0\,\mu\text{C}}{20.0\,\mu\text{F}} = \boxed{2.00\,\text{V}}$$

(*d*) Use $U = \frac{1}{2}QV$ to find the energy stored in each capacitor:

$$U_{10} = \tfrac{1}{2}Q_{10}V_{10} = \tfrac{1}{2}(40.0\,\mu\text{C})(4.00\,\text{V}) = \boxed{80.0\,\mu\text{J}}$$

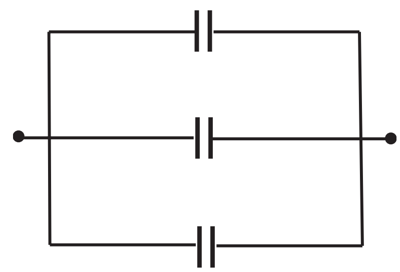
and

$$U_{20} = \tfrac{1}{2}Q_{20}V_{20} = \tfrac{1}{2}(40.0\,\mu\text{C})(2.00\,\text{V}) = \boxed{40.0\,\mu\text{J}}$$

31 •• Three identical capacitors are connected so that their maximum equivalent capacitance, which is 15.0 μF, is obtained. (*a*) Determine how the capacitors are connected and diagram the combination. (*b*) There are three additional ways to connect all three capacitors. Diagram these three ways and determine the equivalent capacitances for each arrangement.

Picture the Problem We can use the properties of capacitors connected in series and in parallel to find the equivalent capacitances for various connection combinations.

(*a*) If their capacitance is to be a maximum, the capacitors must be connected in parallel:



Find the capacitance of each capacitor:

$$C_{eq} = 3C = 15.0\,\mu\text{F} \Rightarrow C = 5.00\,\mu\text{F}$$

(*b*) (1) Connect the three capacitors in series:

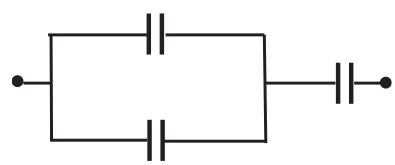
Because the capacitors are in series, their equivalent capacitance is the reciprocal of the sum of their reciprocals:

$$\frac{1}{C_{eq}} = \frac{1}{5.00\,\mu\text{F}} + \frac{1}{5.00\,\mu\text{F}} + \frac{1}{5.00\,\mu\text{F}}$$

and

$$C_{eq} = \boxed{1.67\,\mu\text{F}}$$

(2) Connect two in parallel, with the third in series with that combination:



Find the equivalent capacitance of the two capacitors that are in parallel and then the equivalent capacitance of the network of three capacitors:

$$C_{\substack{\text{eq, two}\\ \text{in parallel}}} = 2(5.00\,\mu\text{F}) = 10.0\,\mu\text{F}$$

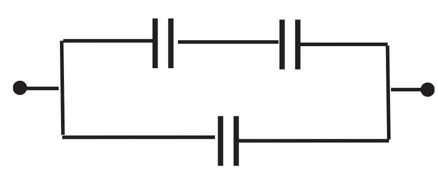
and

$$\frac{1}{C_{eq}} = \frac{1}{10.0\,\mu\text{F}} + \frac{1}{5.00\,\mu\text{F}}$$

Solving for C_{eq} yields:

$$C_{eq} = \boxed{3.33\,\mu\text{F}}$$

(3) Connect two in series, with the third in parallel with that combination:



Find the equivalent capacitance of the two capacitors connected in series:

$$\frac{1}{C_{\text{eq, two in series}}}=\frac{1}{5.00\,\mu\text{F}}+\frac{1}{5.00\,\mu\text{F}}$$

or

$$C_{\text{eq, two in series}}=2.50\,\mu\text{F}$$

Find the capacitance equivalent to 2.50 μF and 5.00 μF in parallel:

$$C_{\text{eq}}=2.50\,\mu\text{F}+5.00\,\mu\text{F}=\boxed{7.50\,\mu\text{F}}$$

32 •• For the circuit shown in Figure 24-36, the capacitors were each discharged before being connected to the voltage source. Find (*a*) the equivalent capacitance of the combination, (*b*) the charge stored on the positively charge plate of each capacitor, (*c*) the voltage across each capacitor, and (*d*) the energy stored in each capacitor.

Picture the Problem We can use the properties of capacitors connected in series and in parallel to find the equivalent capacitance between the terminals and these properties and the definition of capacitance to find the charge on each capacitor.

(*a*) Relate the equivalent capacitance of the two capacitors in series to their individual capacitances:

$$\frac{1}{C_{4+15}}=\frac{1}{4.00\,\mu\text{F}}+\frac{1}{15.0\,\mu\text{F}}$$

Solving for C_{4+15} yields:

$$C_{4+15}=3.158\,\mu\text{F}$$

Find the equivalent capacitance of C_{4+15} in parallel with the 12.0-μF capacitor:

$$C_{\text{eq}}=3.158\,\mu\text{F}+12.0\,\mu\text{F}$$
$$=15.16\,\mu\text{F}=\boxed{15.2\,\mu\text{F}}$$

(*b*) Use the definition of capacitance to find the charge stored on the 12-μF capacitor:

$$Q_{12}=C_{12}V_{12}=C_{12}V=(12.0\,\mu\text{F})(200\,\text{V})$$
$$=\boxed{2.40\,\text{mC}}$$

Because the capacitors in series have the same charge:

$$Q_4=Q_{15}=C_{4+15}V=(3.158\,\mu\text{F})(200\,\text{V})$$
$$=0.6316\,\text{mC}=\boxed{0.632\,\text{mC}}$$

(*c*) Because the 12.0-μF capacitor is connected directly across the source, the voltage across it is:

$$V_{12}=\boxed{200\,\text{V}}$$

Use the definition of capacitance to find V_4 and V_{15}:

$$V_4 = \frac{Q_4}{C_4} = \frac{0.6316\text{ mC}}{4.00\ \mu\text{F}} = \boxed{158\text{ V}}$$

and

$$V_{15} = \frac{Q_{15}}{C_{15}} = \frac{0.6316\text{ mC}}{15.0\ \mu\text{F}} = \boxed{42\text{ V}}$$

(*d*) Use $U = \frac{1}{2}QV$ to find the energy stored in each capacitor:

$$U_4 = \tfrac{1}{2}Q_4V_4 = \tfrac{1}{2}(0.6316\text{ mC})(158\text{ V}) = \boxed{49.9\text{ mJ}}$$

$$U_{15} = \tfrac{1}{2}Q_{15}V_{15} = \tfrac{1}{2}(0.6316\text{ mC})(42\text{ V}) = \boxed{13.3\text{ mJ}}$$

and

$$U_{12} = \tfrac{1}{2}Q_{12}V_{12} = \tfrac{1}{2}(2.40\text{ mC})(200\text{ V}) = \boxed{240\text{ mJ}}$$

33 •• (*a*) Show that the equivalent capacitance of two capacitors in series can be written

$$C_{\text{eq}} = \frac{C_1C_2}{C_1 + C_2}$$

(*b*) Using only this formula and some algebra, show that C_{eq} must always be less than C_1 and C_2, and hence must be less than the smaller of the two values.
(*c*) Show that the equivalent capacitance of three capacitors in series is can be written

$$C_{\text{eq}} = \frac{C_1C_2C_3}{C_1C_2 + C_2C_3 + C_1C_3}$$

(*d*) Using only this formula and some algebra, show that C_{eq} must always be less than each of C_1, C_2 and C_3, and hence must be less than the least of the three values.

Picture the Problem We can use the properties of capacitors in series to establish the results called for in this problem.

(*a*) Express the equivalent capacitance of two capacitors in series:

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{C_2 + C_1}{C_1C_2}$$

Solve for C_{eq} by taking the reciprocal of both sides of the equation to obtain:

$$C_{\text{eq}} = \boxed{\frac{C_1C_2}{C_1 + C_2}}$$

(*b*) Divide numerator and denominator of this expression by C_1 to obtain:

$$C_{eq} = \frac{C_2}{1+\frac{C_2}{C_1}}$$

Because $1+\frac{C_2}{C_1} > 1$:

$$C_{eq} < C_2$$

Divide numerator and denominator of this expression by C_2 to obtain:

$$C_{eq} = \frac{C_1}{1+\frac{C_1}{C_2}}$$

Because $1+\frac{C_1}{C_2} > 1$:

$C_{eq} < C_1$, showing that C_{eq} must always be less than both C_1 and C_2, and hence must be less than the smaller of the two values.

(*c*) Using our result from part (*a*) for two of the capacitors, add a third capacitor C_3 in series to obtain:

$$\frac{1}{C_{eq}} = \frac{C_1+C_2}{C_1C_2} + \frac{1}{C_3} = \frac{C_1C_3 + C_2C_3 + C_1C_2}{C_1C_2C_3}$$

Take the reciprocal of both sides of the equation to obtain:

$$C_{eq} = \boxed{\frac{C_1C_2C_3}{C_1C_2 + C_2C_3 + C_1C_3}}$$

(*d*) Rewrite the result of Part (*c*) as follows:

$$C_{eq} = \left(\frac{C_1C_2}{C_1C_2 + C_2C_3 + C_1C_3}\right)C_3$$

Divide numerator and denominator of this expression by C_1C_2 to obtain:

$$C_{eq} = \left(\frac{1}{\frac{C_1C_2}{C_1C_2} + \frac{C_2C_3}{C_1C_2} + \frac{C_1C_3}{C_1C_2}}\right)C_3 = \left(\frac{1}{1+\frac{C_3}{C_1}+\frac{C_3}{C_2}}\right)C_3$$

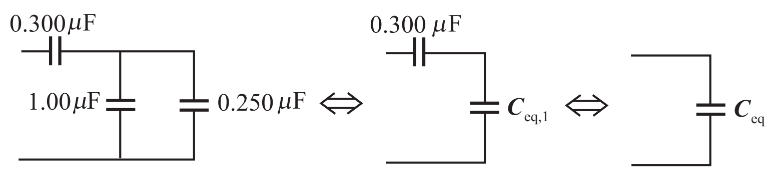
Because $1+\frac{C_3}{C_1}+\frac{C_3}{C_2} > 1$:

$$C_{eq} < C_3$$

Proceed similarly to show that $C_{eq} < C_1$ and $C_{eq} < C_2$. This shows that C_{eq} must always be less than C_1, C_2 and C_3, and hence must be less than the smaller of the three values.

34 •• For the circuit shown in Figure 24-37 find (*a*) the equivalent capacitance between the terminals, (*b*) the charge stored on the positively charge plate of each capacitor, (c) the voltage across each capacitor, and (*d*) the total stored energy.

Picture the Problem Let C_{eq1} represent the equivalent capacitance of the parallel combination and C_{eq} the total equivalent capacitance between the terminals. We can use the equations for capacitors in parallel and then in series to find C_{eq}. Because the charge on C_{eq} is the same as on the 0.300-μF capacitor and C_{eq1}, we'll know the charge on the 0.300-μF capacitor when we have found the total charge Q_{eq} stored by the circuit. We can find the charges on the 1.00-μF and 0.250-μF capacitors by first finding the potential difference across them and then using the definition of capacitance.



(*a*) Find the equivalent capacitance for the parallel combination:

$$C_{eq1} = 1.00\ \mu\text{F} + 0.250\ \mu\text{F} = 1.25\ \mu\text{F}$$

The 0.300-μF capacitor is in series with C_{eq1}. Their equivalent capacitance C_{eq} is given by:

$$\frac{1}{C_{eq}} = \frac{1}{0.300\ \mu\text{F}} + \frac{1}{1.25\ \mu\text{F}}$$

and

$$C_{eq} = 0.24194\ \mu\text{F} = \boxed{0.242\ \mu\text{F}}$$

(*b*) Express the total charge stored by the circuit Q_{eq}:

$$\begin{aligned} Q_{eq} &= Q_{0.300} = Q_{1.25} = C_{eq}V \\ &= (0.24194\ \mu\text{F})(10.0\ \text{V}) \\ &= 2.4194\ \mu\text{C} \end{aligned}$$

The 1.00-μF and 0.250-μF capacitors, being in parallel, have a common potential difference. Express this potential difference in terms of the 10.0 V across the system and the potential difference across the 0.300-μF capacitor:

$$V_{1.25} = 10.0\,\text{V} - V_{0.3} = 10.0\,\text{V} - \frac{Q_{0.3}}{C_{0.3}} = 10.0\,\text{V} - \frac{2.4194\,\mu\text{C}}{0.300\,\mu\text{F}} = 1.935\,\text{V}$$

Using the definition of capacitance, find the charge on the 1.00-μF and 0.250-μF capacitors:

$$Q_{1.00} = C_{1.00}V_{1.00} = (1.00\,\mu\text{F})(1.935\,\text{V}) = \boxed{1.9\,\mu\text{C}}$$

and

$$Q_{0.250} = C_{0.250}V_{0.250} = (0.250\,\mu\text{F})(1.935\,\text{V}) = \boxed{0.48\,\mu\text{C}}$$

Because the voltage across the parallel combination of the 1.00-μF and 0.250-μF capacitors is 1.935 V, the voltage across the 0.300-μF capacitor is 8.065 V and:

$$Q_{0.300} = C_{0.300}V_{0.300} = (0.300\,\mu\text{F})(8.065\,\text{V}) = \boxed{2.42\,\mu\text{C}}$$

(*c*) From (*b*), the voltages across the 0.300-μF capacitor and the parallel combination of the 1.00-μF and 0.250-μF capacitors is:

$$V_{0.300} = \boxed{8.06\,\text{V}}$$

and

$$V_{1.00} = V_{0.250} = 10.0\,\text{V} - 8.06\,\text{V} = \boxed{1.9\,\text{V}}$$

(*d*) The total stored energy is given by:

$$U = \tfrac{1}{2}C_{\text{eq}}V^2$$

Substitute numerical values and evaluate *U*:

$$U = \tfrac{1}{2}(0.2419\,\mu\text{F})(10.0\,\text{V})^2 = \boxed{12.1\,\mu\text{J}}$$

35 •• Five identical capacitors of capacitance C_0 are connected in a so-called "bridge" network, as shown in Figure 24-38. (*a*) What is the equivalent capacitance between points *a* and *b*? (*b*) Find the equivalent capacitance between points *a* and *b* if the capacitor at the center is replaced by a capacitor that has a capacitance of 10 C_0.

Picture the Problem Note that there are three parallel paths between *a* and *b*. We can find the equivalent capacitance of the capacitors connected in series in the upper and lower branches and then find the equivalent capacitance of three capacitors in parallel.

(*a*) Find the equivalent capacitance of the series combination of capacitors in the upper and lower branch:

$$\frac{1}{C_{eq}}=\frac{1}{C_0}+\frac{1}{C_0}\Rightarrow \mathrm{C}_{eq}=\tfrac{1}{2}C_0$$

Now we have two capacitors with capacitance $\frac{1}{2}\boldsymbol{C}_0$ in parallel with a capacitor whose capacitance is C_0. Find their equivalent capacitance:

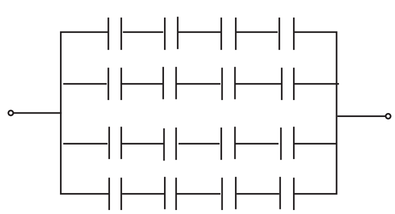
$$C'_{eq}=\tfrac{1}{2}C_0+C_0+\tfrac{1}{2}C_0=\boxed{2C_0}$$

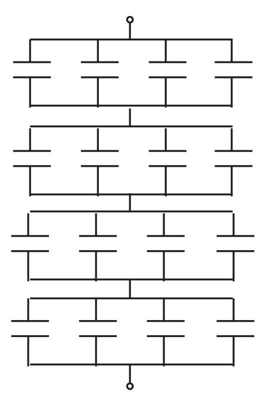
(*b*) If the central capacitance is $10C_0$, then:

$$C'_{eq}=\tfrac{1}{2}C_0+10C_0+\tfrac{1}{2}C_0=\boxed{11C_0}$$

36 •• You and your laboratory team have been given a project by your electrical engineering professor. Your team must design a network of capacitors that has a equivalent capacitance of 2.00 μF and breakdown voltage of 400 V. The restriction is that your team must use only 2.00-μF capacitors that have individual breakdown voltages of 100 V. Diagram the combination.

Picture the Problem Place four of the capacitors in series. Then the potential across each is 100 V when the potential across the combination is 400 V. The equivalent capacitance of the series combination is 0.500 μF. If we place four such series combinations in parallel, as shown in the diagram to the left, the total capacitance between the terminals is 2.00 μF. An alternative arrangement of the capacitors is shown in the diagram to the right. Placing four of the 2.00-μF capacitors in parallel results in an equivalent capacitance of 8.00 μF. Four such combinations connected in series yields a total capacitance of 2.00 μF.





37 •• Find the different equivalent capacitances that can be obtained by using two or three of the following capacitors: a 1.00-μF capacitor, a 2.00-μF capacitor, and a 4.00-μF capacitor.

Picture the Problem We can connect two capacitors in parallel, all three in parallel, two in series, three in series, two in parallel in series with the third, and two in series in parallel with the third.

Connect 2 in parallel to obtain:

$$C_{eq} = 1.00\,\mu\text{F} + 2.00\,\mu\text{F} = \boxed{3.00\,\mu\text{F}}$$

or

$$C_{eq} = 1.00\,\mu\text{F} + 4.00\,\mu\text{F} = \boxed{5.00\,\mu\text{F}}$$

or

$$C_{eq} = 2.00\,\mu\text{F} + 4.00\,\mu\text{F} = \boxed{6.00\,\mu\text{F}}$$

Connect all three in parallel to obtain:

$$C_{eq} = 1.00\,\mu\text{F} + 2.00\,\mu\text{F} + 4.00\,\mu\text{F}$$
$$= \boxed{7.00\,\mu\text{F}}$$

Connect two in series:

$$C_{eq} = \frac{(1.00\,\mu\text{F})(2.00\,\mu\text{F})}{1.00\,\mu\text{F} + 2.00\,\mu\text{F}} = \boxed{0.667\,\mu\text{F}}$$

or

$$C_{eq} = \frac{(1.00\,\mu\text{F})(4.00\,\mu\text{F})}{1.00\,\mu\text{F} + 4.00\,\mu\text{F}} = \boxed{0.800\,\mu\text{F}}$$

or

$$C_{eq} = \frac{(2.00\,\mu\text{F})(4.00\,\mu\text{F})}{2.00\,\mu\text{F} + 4.00\,\mu\text{F}} = \boxed{1.33\,\mu\text{F}}$$

Connecting all three in series yields:

$$C_{eq} = \frac{(1.00\,\mu\text{F})(2.00\,\mu\text{F})(4.00\,\mu\text{F})}{(1.00\,\mu\text{F})(2.00\,\mu\text{F}) + (2.00\,\mu\text{F})(4.00\,\mu\text{F}) + (1.00\,\mu\text{F})(4.00\,\mu\text{F})} = \boxed{0.571\,\mu\text{F}}$$

Connect two in parallel, and the parallel combination in series with the third:

$$C_{eq} = \frac{(4.00\,\mu\text{F})(1.00\,\mu\text{F} + 2.00\,\mu\text{F})}{1.00\,\mu\text{F} + 2.00\,\mu\text{F} + 4.00\,\mu\text{F}}$$
$$= \boxed{1.71\,\mu\text{F}}$$

or

$$C_{eq} = \frac{(1.00\,\mu\text{F})(4.00\,\mu\text{F} + 2.00\,\mu\text{F})}{1.00\,\mu\text{F} + 2.00\,\mu\text{F} + 4.00\,\mu\text{F}}$$
$$= \boxed{0.857\,\mu\text{F}}$$

or

$$C_{eq} = \frac{(2.00\,\mu F)(4.00\,\mu F + 1.00\,\mu F)}{1.00\,\mu F + 2.00\,\mu F + 4.00\,\mu F} = \boxed{1.43\,\mu F}$$

Connect two in series, and the series combination in parallel with the third:

$$C_{eq} = \frac{(1.00\,\mu F)(2.00\,\mu F)}{1.00\,\mu F + 2.00\,\mu F} + 4.00\,\mu F = \boxed{4.67\,\mu F}$$

or

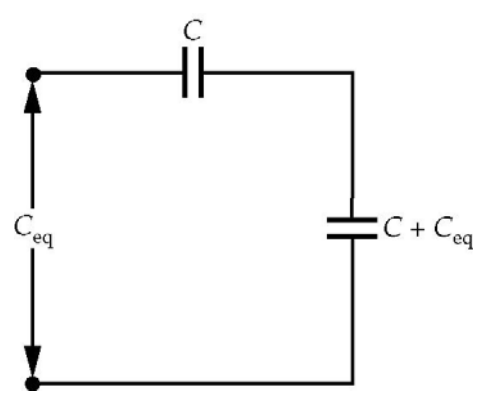
$$C_{eq} = \frac{(4.00\,\mu F)(2.00\,\mu F)}{4.00\,\mu F + 2.00\,\mu F} + 1.00\,\mu F = \boxed{2.33\,\mu F}$$

or

$$C_{eq} = \frac{(1.00\,\mu F)(4.00\,\mu F)}{1.00\,\mu F + 4.00\,\mu F} + 2.00\,\mu F = \boxed{2.80\,\mu F}$$

38 ••• What is the equivalent capacitance (in terms of C which is the capacitance of one of the capacitors) of the infinite ladder of capacitors shown in Figure 24-39?

Picture the Problem Let C be the capacitance of each capacitor in the ladder and let C_{eq} be the equivalent capacitance of the infinite ladder less the series capacitor in the first rung. Because the capacitance is finite and non-zero, adding one more stage to the ladder will not change the capacitance of the network. The capacitance of the two capacitor combination shown to the right is the equivalent of the infinite ladder, so it has capacitance C_{eq} also.



The equivalent capacitance of the parallel combination of C and C_{eq} is: $C + C_{eq}$

The equivalent capacitance of the series combination of C and $(C + C_{eq})$ is C_{eq}, so:

$$\frac{1}{C_{eq}} = \frac{1}{C} + \frac{1}{C + C_{eq}}$$

Simply this expression to obtain a quadratic equation in C_{eq}:

$$C_{eq}^2 + CC_{eq} - C^2 = 0$$

Solving for the positive value of C_{eq} yields:

$$C_{eq} = \left(\frac{\sqrt{5} - 1}{2}\right)C = \boxed{0.618C}$$

Parallel-Plate Capacitors

39 • A parallel-plate capacitor has a capacitance of 2.00 μF and a plate separation of 1.60 mm. (*a*) What is the maximum potential difference between the plates, so that dielectric breakdown of the air between the plates does not occur? (*b*) How much charge is stored at this potential difference?

Picture the Problem The potential difference *V* across a parallel-plate capacitor, the electric field *E* between its plates, and the separation *d* of the plates are related according to $V = Ed$. We can use this relationship to find V_{max} corresponding to dielectric breakdown and the definition of capacitance to find the maximum charge on the capacitor.

(*a*) Express the potential difference *V* across the plates of the capacitor in terms of the electric field between the plates *E* and their separation *d*:

$$V = Ed$$

V_{max} corresponds to E_{max}:

$$V_{max} = (3.00\,\text{MV/m})(1.60\,\text{mm}) = \boxed{4.80\,\text{kV}}$$

(*b*) Using the definition of capacitance, find the charge *Q* stored at this maximum potential difference:

$$Q = CV_{max} = (2.00\,\mu\text{F})(4.80\,\text{kV}) = \boxed{9.60\,\text{mC}}$$

40 • An electric field of 2.00×10^4 V/m exists between the circular plates of a parallel-plate capacitor that has a plate separation of 2.00 mm. (*a*) What is the potential difference across the capacitor plates? (*b*) What plate radius is required if the positively charged plate is to have a charge of 10.0 μC?

Picture the Problem The potential difference V across a parallel-plate capacitor, the electric field E between its plates, and the separation d of the plates are related according to $V = Ed$. In Part (*b*) we can use the definition of capacitance and the expression for the capacitance of a parallel-plate capacitor to find the required plate radius.

(*a*) Express the potential difference V across the plates of the capacitor in terms of the electric field between the plates E and their separation d:

$$V = Ed$$

Substitute numerical values and evaluate V:

$$V = \left(2.00\times10^{4}\ \text{V/m}\right)\left(2.00\,\text{mm}\right) = \boxed{40.0\,\text{V}}$$

(*b*) Use the definition of capacitance to relate the capacitance of the capacitor to its charge and the potential difference across it:

$$C = \frac{Q}{V}$$

The capacitance of a parallel-plate capacitor is given by:

$$C = \frac{\epsilon_0 A}{d} = \frac{\epsilon_0 \pi R^2}{d}$$

where R is the radius of the circular plates.

Equate these two expressions for C:

$$\frac{\epsilon_0 \pi R^2}{d} = \frac{Q}{V} \Rightarrow R = \sqrt{\frac{Qd}{\epsilon_0 \pi V}}$$

Substitute numerical values and evaluate R:

$$R = \sqrt{\frac{\left(10.0\,\mu\text{C}\right)\left(2.00\,\text{mm}\right)}{\pi\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(40.0\,\text{V}\right)}} = \boxed{4.24\,\text{m}}$$

41 •• A parallel-plate, air-gap capacitor has a capacitance of 0.14 μF. The plates are 0.50 mm apart. (*a*) What is the area of each plate? (*b*) What is the potential difference between the plates if the positively charged plate has a charge of 3.2 μC? (*c*) What is the stored energy? (*d*) What is the maximum energy this capacitor can store before dielectric breakdown of the air between the plates occurs?

Picture the Problem We can use the expression for the capacitance of a parallel-plate capacitor to find the area of each plate and the definition of capacitance to find the potential difference when the capacitor is charged to 3.2 μC. We can find the stored energy using $U = \frac{1}{2}CV^2$ and the definition of capacitance and the relationship between the potential difference across a parallel-plate capacitor and the electric field between its plates to find the charge at which dielectric breakdown occurs. Recall that $E_{\text{max, air}} = 3.00$ MV/m.

(*a*) The capacitance of a parallel-plate capacitor is given by:

$$C = \frac{\epsilon_0 A}{d} \Rightarrow A = \frac{Cd}{\epsilon_0}$$

Substitute numerical values and evaluate *A*:

$$A = \frac{(0.14\,\mu\text{F})(0.50\,\text{mm})}{8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}} = 7.906\,\text{m}^2$$

$$= \boxed{7.9\,\text{m}^2}$$

(*b*) Using the definition of capacitance, find the potential difference across the capacitor when it is charged to 3.2 μC:

$$V = \frac{Q}{C} = \frac{3.2\,\mu\text{C}}{0.14\,\mu\text{F}} = 22.9\,\text{V} = \boxed{23\,\text{V}}$$

(*c*) Express the stored energy as a function of the capacitor's capacitance and the potential difference across it:

$$U = \tfrac{1}{2}CV^2$$

Substitute numerical values and evaluate *U*:

$$U = \tfrac{1}{2}(0.14\,\mu\text{F})(22.9\,\text{V})^2 = 36.7\,\mu\text{J}$$

$$= \boxed{37\,\mu\text{J}}$$

(*d*) The maximum energy this capacitor can store before dielectric breakdown of the air between the plates occurs is given by:

$$U_{\text{max}} = \tfrac{1}{2}CV_{\text{max}}^2$$

Relate the maximum potential difference to the maximum electric field between the plates:

$$V_{\text{max}} = E_{\text{max}}d$$

Substituting for V_{max} yields:

$$U_{\text{max}} = \tfrac{1}{2}Cd^2E_{\text{max}}^2$$

Substitute numerical values and evaluate $U_{\max}$:

$$U_{\max} = \tfrac{1}{2}(0.14\,\mu\text{F})(0.50\,\text{mm})^2(3.00\,\text{MV/m})^2 = \boxed{0.16\,\text{J}}$$

42 •• Design a 0.100-μF parallel-plate capacitor that has air between its plates and that can be charged to a maximum potential difference of 1000 V before dielectric breakdown occurs. (*a*) What is the minimum possible separation between the plates? (*b*) What minimum area must each plate of the capacitor have?

Picture the Problem The potential difference across the capacitor plates V is related to their separation d and the electric field between them according to $V = Ed$. We can use this equation with $E_{\max}$ = 3.00 MV/m to find $d_{\min}$. In Part (*b*) we can use the expression for the capacitance of a parallel-plate capacitor to find the required area of the plates.

(*a*) Use the relationship between the potential difference across the plates and the electric field between them to find the minimum separation of the plates:

$$d_{\min} = \frac{V}{E_{\max}} = \frac{1000\,\text{V}}{3.00\,\text{MV/m}} = \boxed{0.333\,\text{mm}}$$

(*b*) The capacitance of a parallel-plate capacitor is given by:

$$C = \frac{\epsilon_0 A}{d} \Rightarrow A = \frac{Cd}{\epsilon_0}$$

Substitute numerical values and evaluate A:

$$A = \frac{(0.100\,\mu\text{F})(0.333\,\text{mm})}{8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2} = \boxed{3.76\,\text{m}^2}$$

Cylindrical Capacitors

43 • In preparation for an experiment that you will do in your introductory nuclear physics lab, you are shown the inside of a Geiger tube. You measure the radius and the length of the central wire of the Geiger tube to be 0.200 mm and 12.0 cm, respectively. The outer surface of the tube is a conducing cylindrical shell that has an inner radius of 1.50 cm. The shell is coaxial with the wire and has the same length (12.0 cm). Calculate (*a*) the capacitance of your tube, assuming that the gas in the tube has a dielectric constant of 1.00, and (*b*) the value of the linear charge density on the wire when the potential difference between the wire and shell is 1.20 kV?

Picture the Problem The capacitance of a cylindrical capacitor is given by $C = 2\pi\kappa \in_0 L/\ln(R_2/R_1)$ where L is its length and R_1 and R_2 the radii of the inner and outer conductors.

(*a*) The capacitance of the coaxial cylindrical shell is given by:

$$C = \frac{2\pi\kappa \in_0 L}{\ln\left(\frac{R_2}{R_1}\right)}$$

Substitute numerical values and evaluate C:

$$C = \frac{2\pi(1.00)(8.854\times10^{-12}\ \mathrm{C^2/N\cdot m^2})(0.120\ \mathrm{m})}{\ln\left(\frac{1.50\ \mathrm{cm}}{0.200\ \mathrm{mm}}\right)} = 1.546\ \mathrm{pF} = \boxed{1.55\ \mathrm{pF}}$$

(*b*) Use the definition of capacitance to express the charge per unit length:

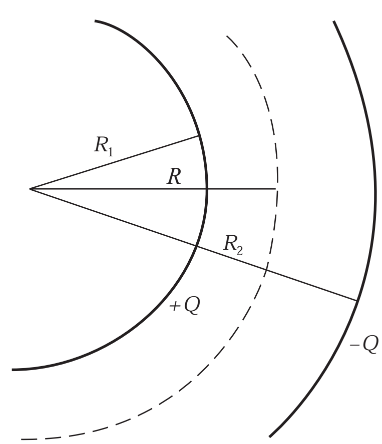
$$\lambda = \frac{Q}{L} = \frac{CV}{L}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{(1.546\ \mathrm{pF})(1.20\ \mathrm{kV})}{0.120\ \mathrm{m}} = \boxed{15.5\ \mathrm{nC/m}}$$

44 •• A cylindrical capacitor consists of a long wire that has a radius R_1, a length L and a charge $+Q$. The wire is enclosed by a coaxial outer cylindrical shell that has a inner radius R_2, length L, and charge $-Q$. (*a*) Find expressions for the electric field and energy density as a function of the distance R from the axis. (*b*) How much energy resides in a region between the conductors that has a radius R, a thickness dR, and a volume $2\pi rL\ dR$? (*c*) Integrate your expression from Part (*b*) to find the total energy stored in the capacitor. Compare your result with that obtained by using the formula $U = Q^2/(2C)$ in conjunction with the known expression for the capacitance of a cylindrical capacitor.

Picture the Problem The diagram shows a partial cross-sectional view of the inner wire and the outer cylindrical shell. By symmetry, the electric field is radial in the space between the wire and the concentric cylindrical shell. We can apply Gauss's law to cylindrical surfaces of radii $R < R_1$, $R_1 < R < R_2$, and $R > R_2$ to find the electric field and, hence, the energy density in these regions.



(*a*) Apply Gauss's law to a cylindrical surface of radius $R < R_1$ and length L to obtain:

$$E_{R<R_1}(2\pi RL) = \frac{Q_{\text{inside}}}{\epsilon_0} = 0$$

and

$$E_{R<R_1} = \boxed{0}$$

Because $E = 0$ for $R < R_1$:

$$u_{R<R_1} = \boxed{0}$$

Apply Gauss's law to a cylindrical surface of radius $R_1 < R < R_2$ and length L to obtain:

$$E_{R_1<R<R_2}(2\pi RL) = \frac{Q_{\text{inside}}}{\epsilon_0} = \frac{\lambda L}{\epsilon_0}$$

where λ is the linear charge density.

Solve for $E_{R_1<R<R_2}$ to obtain:

$$E_{R_1<R<R_2} = \frac{\lambda}{2\pi \epsilon_0 R} = \boxed{\frac{2kQ}{RL}}$$

The energy density in the region $R_1 < R < R_2$ is given by:

$$u_{R_1<R<R_2} = \tfrac{1}{2}\epsilon_0 E^2_{R_1<R<R_2}$$

Substituting for $E_{R_1<R<R_2}$ and simplifying yields:

$$u_{R_1<R<R_2} = \tfrac{1}{2}\epsilon_0\left(\frac{2k\lambda}{R}\right)^2 = \tfrac{1}{2}\epsilon_0\left(\frac{2kQ}{RL}\right)^2$$
$$= \boxed{\frac{2k^2\epsilon_0 Q^2}{R^2L^2}}$$

Apply Gauss's law to a cylindrical surface of radius $R > R_2$ and length L to obtain:

$$E_{R>R_2}(2\pi RL) = \frac{Q_{\text{inside}}}{\epsilon_0} = 0$$

and

$$E_{R>R_2} = \boxed{0}$$

Because $E = 0$ for $R > R_2$:

$$u_{R>R_2} = \boxed{0}$$

(*b*) Express the energy residing in a cylindrical shell between the conductors of radius R, thickness dR, and volume $2\pi RL\,dR$:

$$dU = 2\pi RLu(R)dR$$
$$= 2\pi RL\left(\frac{2k^2\epsilon_0 Q^2}{R^2L^2}\right)dr$$
$$= \boxed{\frac{kQ^2}{RL}dR}$$

(c) Integrate dU from $R = R_1$ to $R = R_2$ to obtain:

$$U = \frac{kQ^2}{L}\int_{R_1}^{R_2}\frac{dR}{R} = \boxed{\frac{kQ^2}{L}\ln\left(\frac{R_2}{R_1}\right)}$$

Use $U = \frac{1}{2}CV^2$ and the expression for the capacitance of a cylindrical capacitor to obtain:

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\frac{Q^2}{C} = \frac{Q^2}{2\left(\dfrac{2\pi \in_0 L}{\ln\left(\dfrac{R_2}{R_1}\right)}\right)} = \boxed{\frac{kQ^2}{L}\ln\left(\frac{R_2}{R_1}\right)}$$

in agreement with the result from Part (b).

45 ••• Three concentric, thin long conducting cylindrical shells have radii of 2.00 mm, 5.00 mm, and 8.00 mm. The space between the shells is filled with air. The innermost and outermost shells are connected at one end by a conducting wire. Find the capacitance per unit length of this configuration.

Picture the Problem Note that with the innermost and outermost cylinders connected together the system corresponds to two cylindrical capacitors connected in parallel. We can use $C = \dfrac{2\pi \in_0 \kappa L}{\ln(R_2/R_1)}$ to express the capacitance per unit length and then calculate and add the capacitances per unit length of each of the cylindrical shell capacitors.

Relate the capacitance of a cylindrical capacitor to its length L and inner and outer radii R_1 and R_2:

$$C = \frac{2\pi \in_0 \kappa L}{\ln(R_2/R_1)}$$

Divide both sides of the equation by L to express the capacitance per unit length:

$$\frac{C}{L} = \frac{2\pi \in_0 \kappa}{\ln(R_2/R_1)}$$

Express the capacitance per unit length of the cylindrical system:

$$\frac{C}{L} = \left(\frac{C}{L}\right)_{\text{outer}} + \left(\frac{C}{L}\right)_{\text{inner}} \qquad (1)$$

Substitute numerical values and evaluate the capacitance per unit length of the outer cylindrical shell combination:

$$\left(\frac{C}{L}\right)_{\text{outer}} = \frac{2\pi\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)(1.00)}{\ln(0.800\,\text{cm}/0.500\,\text{cm})} = 118.4\,\text{pF/m}$$

Substitute numerical values and evaluate capacitance per unit length of the inner cylindrical shell combination:

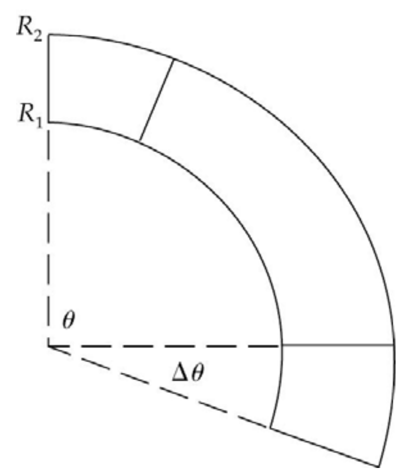
$$\left(\frac{C}{L}\right)_{\text{inner}} = \frac{2\pi\left(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2\right)(1.00)}{\ln(0.500\,\text{cm}/0.200\,\text{cm})} = 60.7\,\text{pF/m}$$

Substituting numerical results in equation (1) yields:

$$\frac{C}{L} = 118.4\,\text{pF/m} + 60.7\,\text{pF/m} = \boxed{179\,\text{pF/m}}$$

46 ••• A *goniometer* is a precise instrument for measuring angles. A *capacitive goniometer* is shown in Figure 24-40*a*. Each plate of the variable capacitor (Figure 24-40*b*) consists of a flat metal semicircle that has an inner radius R_1 and an outer radius R_2. The plates share a common rotation axis, and the width of the air gap separating the plates is d. Calculate the capacitance as a function of the angle θ and the parameters given.

Picture the Problem We can use the expression for the capacitance of a parallel-plate capacitor of variable area and the geometry of the figure to express the capacitance of the goniometer.



The capacitance of the parallel-plate capacitor is given by:

$$C = \frac{\in_0 (A - \Delta A)}{d}$$

The area of the plates is:

$$A = \pi\left(R_2^2 - R_1^2\right)\frac{\theta}{2\pi} = \left(R_2^2 - R_1^2\right)\frac{\theta}{2}$$

If the top plate rotates through an angle $\Delta\theta$, then the area is reduced by:

$$\Delta A = \pi\left(R_2^2 - R_1^2\right)\frac{\Delta\theta}{2\pi} = \left(R_2^2 - R_1^2\right)\frac{\Delta\theta}{2}$$

Substitute for A and ΔA in the expression for C and simplify to obtain:

$$C = \frac{\epsilon_0}{d}\left[\left(R_2^2 - R_1^2\right)\frac{\theta}{2} - \left(R_2^2 - R_1^2\right)\frac{\Delta\theta}{2}\right]$$

$$= \boxed{\frac{\epsilon_0\left(R_2^2 - R_1^2\right)}{2d}(\theta - \Delta\theta)}$$

47 ••• A *capacitive pressure gauge* is shown in Figure 24-41. Each plate has an area A. The plates are separated by a material that has a dielectric constant κ, a thickness d, and a Young's modulus Y. If a pressure increase of ΔP is applied to the plates, derive an expression for the change in capacitance.

Picture the Problem Because A is constant, we can differentiate the expression for the capacitance of a dielectric-filled parallel-plate capacitor with respect to the plate separation d and use a differential approximation to find the change in its capacitance ΔC resulting from a pressure increase ΔP. We can then use the definition of Young's modulus to eliminate the plate separation (thickness of the dielectric material) from this expression.

The capacitance of a dielectric-filled parallel-plate capacitor is given by:

$$C = \frac{\kappa \epsilon_0 A}{d}$$

Differentiating this expression with respect to d gives:

$$\frac{dC}{dd} = -\frac{\kappa \epsilon_0 A}{d^2}$$

or, using a differential approximation,

$$\frac{\Delta C}{\Delta d} \approx -\frac{\kappa \epsilon_0 A}{d^2}$$

Solving for ΔC and simplifying yields:

$$\Delta C \approx -\frac{\kappa \epsilon_0 A}{d^2}\Delta d = -\frac{\kappa \epsilon_0 A}{d}\left(\frac{\Delta d}{d}\right)$$

$$= -C\left(\frac{\Delta d}{d}\right)$$

From the definition of Young's modulus we have:

$$Y = \frac{P}{\Delta d/d} \Rightarrow \frac{\Delta d}{d} = -\frac{P}{Y}$$

Substituting for $\Delta d/d$ yields:

$$\Delta C = \boxed{-C\left(\frac{P}{Y}\right)}$$

Spherical Capacitors

48 •• Model Earth as a conducting sphere. (*a*) What is its self-capacitance? (*b*) Assume the magnitude of the electric field at Earth's surface is 150 V/m. What charge density does this correspond to? Express this value in fundamental charge units *e* per square centimeter

Picture the Problem (*a*) We can use the definition of capacitance and the expression for the electric potential at the surface of Earth to find Earth's self-capacitance. In Part (*b*) we can use $E = \sigma/\epsilon_0$ to find Earth's surface charge density.

(*a*) The self-capacitance of Earth is given by:

$C = \dfrac{Q}{V}$ where Q is the charge on Earth and V is the potential at its surface.

Because $V = \dfrac{kQ}{R}$ where R is the radius of Earth:

$$C = \frac{Q}{\frac{kQ}{R}} = \frac{R}{k}$$

Substitute numerical values and evaluate C:

$$C = \frac{6370\text{ km}}{8.988\times10^{9}\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}} = 0.7087\text{ mF}$$

$$= \boxed{0.709\text{ mF}}$$

(*b*) The electric field at the surface of Earth is related to Earth's charge density:

$$E = \frac{\sigma}{\epsilon_0} \Rightarrow \sigma = \epsilon_0 E$$

Substitute numerical values and evaluate σ:

$$\sigma = \left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(150\ \frac{\text{V}}{\text{m}}\right) = 1.328\frac{\text{nC}}{\text{m}^2}\times\left(\frac{1\text{ m}}{10^2\text{ cm}}\right)^2\times\frac{1e}{1.602\times10^{-19}\text{ C}}$$

$$= \boxed{829\times10^{3}\ \frac{e}{\text{cm}^2}}$$

49 •• **[SSM]** A spherical capacitor consists of a thin spherical shell that has a radius R_1 and a thin, concentric spherical shell that has a radius R_2, where $R_2 > R_1$. (*a*) Show that the capacitance is given by $C = 4\pi\epsilon_0 R_1R_2/(R_2 - R_1)$.

(*b*) Show that when the radii of the shells are nearly equal, the capacitance approximately is given by the expression for the capacitance of a parallel-plate capacitor, $C = \epsilon_0 A/d$, where A is the area of the sphere and $d = R_2 - R_1$.

Picture the Problem We can use the definition of capacitance and the expression for the potential difference between charged concentric spherical shells to show that $C = 4\pi\epsilon_0 R_1R_2/(R_2 - R_1)$.

(*a*) Using its definition, relate the capacitance of the concentric spherical shells to their charge Q and the potential difference V between their surfaces:

$$C = \frac{Q}{V}$$

Express the potential difference between the conductors:

$$V = kQ\left(\frac{1}{R_1} - \frac{1}{R_2}\right) = kQ\frac{R_2 - R_1}{R_1R_2}$$

Substitute for V and simplify to obtain:

$$C = \frac{Q}{kQ\dfrac{R_2 - R_1}{R_1R_2}} = \frac{R_1R_2}{k(R_2 - R_1)} = \boxed{\frac{4\pi\epsilon_0 R_1R_2}{R_2 - R_1}}$$

(*b*) Because $R_2 = R_1 + d$:

$$\begin{aligned} R_1R_2 &= R_1(R_1 + d) \\ &= R_1^2 + R_1d \\ &\approx R_1^2 = R^2 \end{aligned}$$

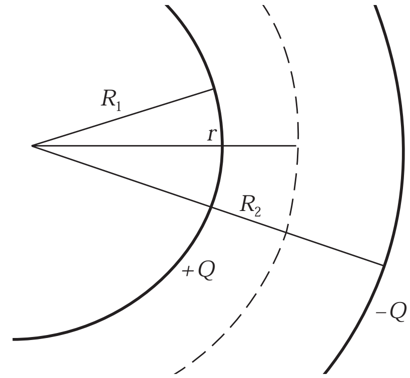
because d is small.

Substitute to obtain:

$$C \approx \frac{4\pi\epsilon_0 R^2}{d} = \boxed{\frac{\epsilon_0 A}{d}}$$

50 •• A spherical capacitor is composed of an inner sphere which has a radius R_1 and a charge $+Q$ and an outer concentric spherical thin shell which has a radius R_2 and a charge $-Q$. (*a*) Find the electric field and the energy density as a function of r, where r is the distance from the center of the sphere, for $0 \le r < \infty$. (*b*) Calculate the energy associated with the electrostatic field in a spherical shell between the conductors that has a radius r, a thickness dr, and a volume $4\pi r^2\,dr$? (*c*) Integrate your expression from Part (*b*) to find the total energy and compare your result with the result obtained using $U = \frac{1}{2}QV$.

Picture the Problem The diagram shows a partial cross-sectional view of the inner and outer spherical shells. By symmetry, the electric field is radial. We can apply Gauss's law to spherical surfaces of radii $r < R_1$, $R_1 < r < R_2$, and $r > R_2$ to find the electric field and, hence, the energy density in these regions.



(*a*) Apply Gauss's law to a spherical surface of radius $r < R_1$ to obtain:

$$E_r\left(4\pi r^2\right) = \frac{Q_{\text{inside}}}{\epsilon_0} = 0$$

and, because $Q_{\text{inside}} = 0$,

$$E_r = \boxed{0}$$

Because $E = 0$ for $r < R_1$:

$$u = \boxed{0}$$

Apply Gauss's law to a spherical surface of radius $R_1 < r < R_2$ to obtain:

$$E_r\left(4\pi r^2\right) = \frac{Q_{\text{inside}}}{\epsilon_0} = \frac{Q}{\epsilon_0}$$

Solve for E_r to obtain:

$$E_{r_2} = \frac{Q}{4\pi \epsilon_0 r^2} = \boxed{\frac{kQ}{r^2}} \quad R_1 \le r \le R_2$$

Express the energy density in the region $R_1 < r < R_2$:

$$u = \tfrac{1}{2}\epsilon_0 E^2_{R_1<r<R_2} = \tfrac{1}{2}\epsilon_0\left(\frac{kQ}{r^2}\right)^2$$

$$= \boxed{\frac{k^2 \epsilon_0 Q^2}{2r^4}} \quad R_1 \le r \le R_2$$

Apply Gauss's law to a cylindrical surface of radius $r > R_2$ to obtain:

$$E_r\left(4\pi r^2\right) = \frac{Q_{\text{inside}}}{\epsilon_0} = 0$$

and, because $Q_{\text{inside}} = 0$,

$$E_r = \boxed{0}$$

Because $E = 0$ for $r > R_2$:

$$u_r = \boxed{0}$$

(*b*) Express the energy in the electrostatic field in a spherical shell of radius *r*, thickness *dr*, and volume $4\pi r^2 dr$ between the conductors:

$$dU = 4\pi r^2 u(r)dr = 4\pi r^2\left(\frac{k^2 \in_0 Q^2}{2r^4}\right)dr$$

$$= \boxed{\frac{kQ^2}{2r^2}dr}$$

(*c*) Integrate *dU* from $r = R_1$ to R_2 to obtain:

$$U = \frac{kQ^2}{2}\int_{R_1}^{R_2}\frac{dr}{r^2} = \frac{kQ^2(R_2 - R_1)}{2R_1R_2}$$

$$= \boxed{\frac{1}{2}Q^2\left(\frac{R_2 - R_1}{4\pi \in_0 R_1R_2}\right)}$$

Note that the quantity in parentheses is $1/C$, so we have $U = \frac{1}{2}Q^2/C$.

51 ••• An isolated conducting sphere of radius *R* has a charge *Q* distributed uniformly over its surface. Find the distance *R*′ from the center of the sphere such that half the total electrostatic energy of the system is associated with the electric field beyond that distance.

Picture the Problem We know, from Gauss's law, that the field inside the shell is zero. We can then express the energy in the electrostatic field in a spherical shell of radius *r*, thickness *dr*, and volume $4\pi r^2 dr$ outside the given spherical shell and find the total energy in the electric field by integrating from *R* to ∞. If we then integrate the same expression from *R* to *R*′ we can find the distance *R*′ from the center of the sphere such that half the total electrostatic field energy of the system is within that distance.

Apply Gauss's law to a spherical shell of radius $r > R$ to obtain:

$$E_{r>R}\left(4\pi r^2\right) = \frac{Q_{\text{inside}}}{\in_0} = \frac{Q}{\in_0}$$

Solve for $E_{r>R}$ outside the spherical shell:

$$E_{r>R} = \frac{kQ}{r^2}$$

Express the energy density in the region $r > R$:

$$u = \tfrac{1}{2}\in_0 E_{r>R}^2 = \tfrac{1}{2}\in_0\left(\frac{kQ}{r^2}\right)^2 = \frac{k^2 \in_0 Q^2}{2r^4}$$

Express the energy in the electrostatic field in a spherical shell of radius *r*, thickness *dr*, and volume $4\pi r^2 dr$ outside the spherical shell:

$$dU = 4\pi r^2 u(r)dr$$

$$= 4\pi r^2\left(\frac{k^2 \in_0 Q^2}{2r^4}\right)dr$$

$$= \frac{kQ^2}{2r^2}dr$$

Integrate dU from R to ∞ to obtain:

$$U_{\text{tot}} = \frac{kQ^2}{2}\int_R^\infty \frac{dr}{r^2} = \frac{kQ^2}{2R}$$

Integrate dU from R to R' to obtain:

$$U = \frac{kQ^2}{2}\int_R^{R'} \frac{dr}{r^2} = \frac{kQ^2}{2}\left(\frac{1}{R} - \frac{1}{R'}\right)$$

Set $U = \frac{1}{2}U_{\text{tot}}$ to obtain:

$$\frac{kQ^2}{2}\left(\frac{1}{R} - \frac{1}{R'}\right) = \frac{kQ^2}{4R} \Rightarrow R' = \boxed{2R}$$

Disconnected and Reconnected Capacitors

52 •• A 2.00-μF capacitor is energized to a potential difference of 12.0 V. The wires connecting the capacitor to the battery are then disconnected from the battery and connected across a second, initially uncharged, capacitor. The potential difference across the 2.00-μF capacitor then drops to 4.00 V. What is the capacitance of the second capacitor?

Picture the Problem Let C_1 represent the capacitance of the 2.00-μF capacitor and C_2 the capacitance of the 2nd capacitor. Note that when they are connected as described in the problem statement they are in parallel and, hence, share a common potential difference V'. We can use the equation for the equivalent capacitance of two capacitors in parallel and the definition of capacitance to relate C_2 to C_1 and to the charge stored in and the potential difference across the equivalent capacitor.

Using the definition of capacitance, find the charge on capacitor C_1:

$$Q_1 = C_1V = (2.00\,\mu\text{F})(12.0\,\text{V}) = 24.0\,\mu\text{C}$$

Express the equivalent capacitance of the two-capacitor system and solve for C_2:

$$C_{\text{eq}} = C_1 + C_2 \Rightarrow C_2 = C_{\text{eq}} - C_1$$

Using the definition of capacitance, express C_{eq} in terms of the total charge Q' of the two-capacitor system and the common potential difference V' across the capacitors:

$$C_{\text{eq}} = \frac{Q'}{V'}$$

Substitute for C_{eq} to obtain:

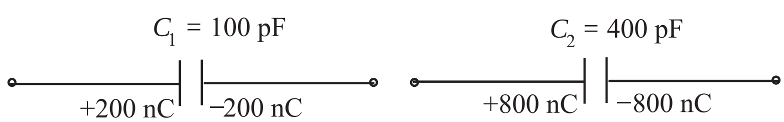
$$C_2 = \frac{Q'}{V'} - C_1$$

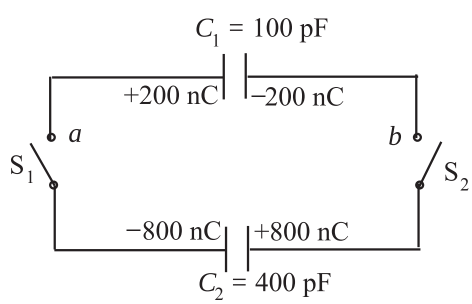
Substitute numerical values and evaluate C_2:

$$C_2 = \frac{24.0\,\mu\text{C}}{4.00\,\text{V}} - 2.00\,\mu\text{F} = \boxed{4.00\,\mu\text{F}}$$

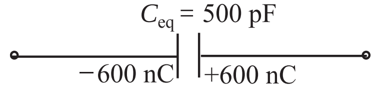
53 •• [SSM] A 100-pF capacitor and a 400-pF capacitor are both charged to 2.00 kV. They are then disconnected from the voltage source and are connected together, positive plate to negative plate and negative plate to positive plate. (*a*) Find the resulting potential difference across each capacitor. (*b*) Find the energy dissipated when the connections are made.

Picture the Problem (*a*) Just after the two capacitors are disconnected from the voltage source, the 100-pF capacitor carries a charge of 200 nC and the 400-pF capacitor carries a charge of 800 nC. After switches S_1 and S_2 in the circuit are closed, the capacitors are in parallel between points *a* and *b*, and the equivalent capacitance of the system is $C_{eq} = C_{100} + C_{400}$. The plates to the right in the diagram below form a single conductor with a charge of 600 nC, and the plates to the left form a conductor with charge $-Q = -600$ nC. The potential difference across each capacitor is $V = Q/C_{eq}$. In Part (*b*) we can find the energy dissipated when the connections are made by subtracting the energy stored in the system after they are connected from the energy stored in the system before they are connected.





(*a*) When the switches are closed and the capacitors are connected together, their initial charges redistribute and the final charge on the two-capacitor system is 600 nC and the equivalent capacitance is 500 pF:



The potential difference across each capacitor is the potential difference across the equivalent capacitor:

$$V = \frac{Q}{C_{eq}} = \frac{600\text{ nC}}{500\text{ pF}} = \boxed{1.20\text{ kV}}$$

(*b*) The energy dissipated when the capacitors are connected is the difference between the energy stored after they are connected and the energy stored before they were connected:

$$U_{dissipated} = U_{before} - U_{after} \quad (1)$$

U_{before} is given by:

$$U_{before} = U_1 + U_2 = \tfrac{1}{2}Q_1V_1 + \tfrac{1}{2}Q_2V_2 = \tfrac{1}{2}(Q_1 + Q_2)V_i$$

where V_i is the charging voltage.

U_{after} is given by:

$$U_{after} = \tfrac{1}{2}QV$$

where Q is the total charge stored after the capacitors have been connected and V is the voltage found in Part (*a*).

Substitute for U_{before} and U_{after} in equation (1) and simplify to obtain:

$$U_{dissipated} = \tfrac{1}{2}(Q_1 + Q_2)V_i - \tfrac{1}{2}QV$$

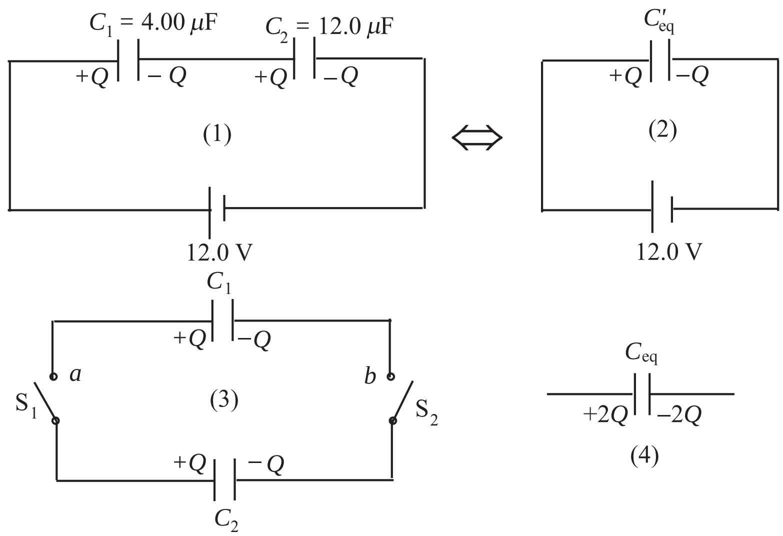
Substitute numerical values and evaluate $U_{dissipated}$:

$$U_{dissipated} = \tfrac{1}{2}(200\text{ nC} + 800\text{ nC})(2.00\text{ kV}) - \tfrac{1}{2}(600\text{ nC})(1.20\text{ kV}) = \boxed{640\ \mu\text{J}}$$

54 •• Two capacitors, one that has a capacitance of 4.00 μF and one that has a capacitance of 12.0 μF, are first discharged and then are connected in series. The series combination is then connected across the terminals of a 12.0-V battery. Next they are carefully disconnected so that they are not discharged and they are then reconnected to each other—positive plate to positive plate and negative plate to negative plate. (*a*) Find the potential difference across each capacitor after they are reconnected. (*b*) Find the energy stored in the capacitors before they are disconnected from the battery, and find the energy stored after they are reconnected.

Picture the Problem Let C_1 represent the capacitance of the 4.00-μF capacitor and C_2 the capacitance of the 12.0-μF capacitor. (*a*) Just after the two capacitors are disconnected from the battery, they both carry charge Q. After switches S_1

and S_2 in the circuit are closed, the capacitors are in parallel between points *a* and *b,* and each will have the charge it acquired while they were connected in series across the battery. We can use the definition of capacitance and the equivalent capacitance of the two capacitors to find the common potential difference across them. In Part (*b*) we can use $U = \frac{1}{2}CV^2$ to find the initial and final energy stored in the capacitors.



(*a*) From diagram (4):

$$V_{4.00} = V_{12.0} = \frac{2Q}{C_{eq}} \quad (1)$$

where Q is the charge on each capacitor *before* they are disconnected.

Find the equivalent capacitance of the two capacitors when they are connected in parallel:

$$C_{eq} = C_1 + C_2 = 4.00\,\mu\text{F} + 12.0\,\mu\text{F} = 16.0\,\mu\text{F}$$

Express the charge Q on each capacitor before they are disconnected:

$$Q = C'_{eq}V$$

Express the equivalent capacitance of the two capacitors connected in series:

$$C'_{eq} = \frac{C_1C_2}{C_1 + C_2} = \frac{(4.00\,\mu\text{F})(12.0\,\mu\text{F})}{4.00\,\mu\text{F} + 12.0\,\mu\text{F}} = 3.00\,\mu\text{F}$$

Substitute to find Q:

$$Q = (3.00\,\mu\text{F})(12.0\,\text{V}) = 36.0\,\mu\text{C}$$

Substitute numerical values for Q and C_{eq} in equation (1) and evaluate $V_{4.00} = V_{12.0}$:

$$V_{4.00} = V_{12.0} = \frac{2(36.0\,\mu\text{C})}{16.0\,\mu\text{F}} = \boxed{4.50\,\text{V}}$$

(*b*) The energy stored in the capacitors initially is:

$$U_i = \tfrac{1}{2}C'_{eq}V_i^2 = \tfrac{1}{2}(3.00\,\mu\text{F})(12.0\,\text{V})^2 = \boxed{216\,\mu\text{J}}$$

The energy stored in the capacitors when they have been reconnected is:

$$U_f = \tfrac{1}{2}C_{eq}V_f^2 = \tfrac{1}{2}(16.0\,\mu\text{F})(4.50\,\text{V})^2 = \boxed{162\,\mu\text{J}}$$

55 •• A 1.2-μF capacitor is charged to 30 V. After charging, the capacitor is disconnected from the voltage source and is connected across the terminals of a second capacitor that had previously been discharged. The final voltage across the 1.2-μF capacitor is 10 V. (*a*) What is the capacitance of the second capacitor? (*b*) How much energy was dissipated when the connection was made?

Picture the Problem Let C_1 represent the capacitance of the 1.2-μF capacitor and C_2 the capacitance of the 2nd capacitor. Note that when they are connected as described in the problem statement they are in parallel and, hence, share a common potential difference. We can use the equation for the equivalent capacitance of two capacitors in parallel and the definition of capacitance to relate C_2 to C_1 and to the charge stored in and the potential difference across the equivalent capacitor. In Part (*b*) we can use $U = \tfrac{1}{2}CV^2$ to find the energy before and after the connection was made and, hence, the energy dissipated when the connection was made.

(*a*) Using the definition of capacitance, find the charge on capacitor C_1:

$$Q_1 = C_1V = (1.2\,\mu\text{F})(30\,\text{V}) = 36\,\mu\text{C}$$

Because the capacitors are in parallel:

$$C_{eq} = C_1 + C_2 \Rightarrow C_2 = C_{eq} - C_1 \quad (1)$$

Using the definition of capacitance, express C_{eq} in terms of the charge Q_2 on the second capacitor and the common potential difference V_2 across the two capacitors:

$$C_{eq} = \frac{Q_2}{V_2} = \frac{Q_1}{V_2}$$

Substituting for C_{eq} in equation (1) yields:

$$C_2 = \frac{Q_1}{V_2} - C_1$$

Substitute numerical values and evaluate C_2:

$$C_2 = \frac{36\,\mu\text{C}}{10\,\text{V}} - 1.2\,\mu\text{F} = \boxed{2.4\,\mu\text{F}}$$

(*b*) The energy dissipated when the connections are made in terms of the energy stored in the capacitors before and after their connection is given by:

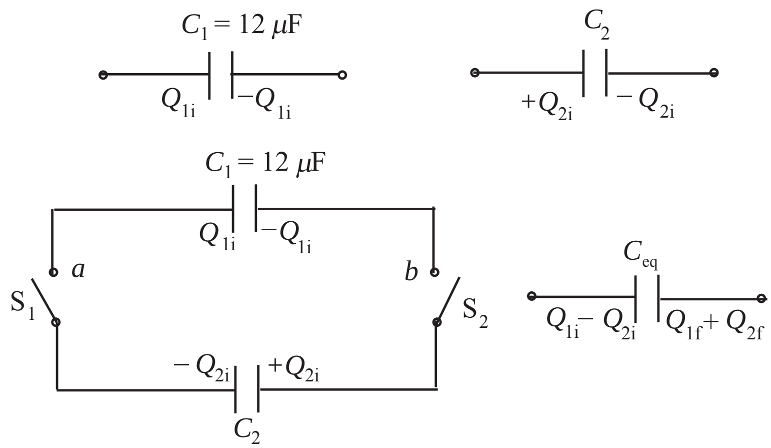
$$\begin{aligned} U_{\text{dissipated}} &= U_{\text{before}} - U_{\text{after}} \\ &= \tfrac{1}{2}C_1V_1^2 - \tfrac{1}{2}C_{\text{eq}}V_{\text{f}}^2 \\ &= \tfrac{1}{2}\left(C_1V_1^2 - C_{\text{eq}}V_{\text{f}}^2\right) \end{aligned}$$

Substitute numerical values and evaluate $U_{\text{dissipated}}$:

$$U_{\text{dissipated}} = \tfrac{1}{2}\left[(1.2\,\mu\text{F})(30\,\text{V})^2 - (3.6\,\mu\text{F})(10\,\text{V})^2\right] = \boxed{0.4\,\text{mJ}}$$

56 •• A 12-μF capacitor and a capacitor of unknown capacitance are both charged to 2.00 kV. After charging, the capacitors are disconnected from the voltage source. The capacitors are then connected to each other—positive plate to negative plate and negative plate to positive plate. The final voltage across the 12-μF capacitor is 1.00 kV. (*a*) What is the capacitance of the second capacitor? (*b*) How much energy was dissipated when the connection was made?

Picture the Problem Let C_1 represent the capacitance of the 12-μF capacitor and C_2 the capacitance of the second capacitor. (*a*) Just after the two capacitors are disconnected from the voltage source, the 12-μF capacitor carries a charge of Q_{1i} = 24 mC and the unknown capacitor carries a charge Q_{2i}. After switches S_1 and S_2 in the circuit are closed, the capacitors are in parallel between points *a* and *b,* and the equivalent capacitance of the system is $C_{\text{eq}} = C_1 + C_2$. The plates to the right in the diagram below form a single conductor with a charge of $Q_{1i} - Q_{2i}$, and the plates to the left form a conductor with charge $Q_{1f} + Q_{2f}$, where Q_{1i}, Q_{2i}, Q_{1f} and Q_{2f} are all positive . Because they are in parallel, the potential difference across both C_1 and C_2 when they are connected is 1.00 kV. In Part (*b*) we can find the energy dissipated when the connections are made by subtracting the energy stored in the system after they are connected from the energy stored in the system before they are connected.



(*a*) When the switches are closed and the capacitors are connected together, their initial charges redistribute. Apply conservation of charge to obtain:

$$Q_{1i} - Q_{2i} = Q_{1f} + Q_{2f}$$

or

$$C_1V_i - C_2V_i = C_1V_f + C_2V_f$$

Solving for C_2 yields:

$$C_2 = \frac{V_i - V_f}{V_i + V_f}C_1$$

Substitute numerical values and evaluate C_2:

$$C_2 = \left(\frac{2.00\ \text{kV} - 1.00\ \text{kV}}{2.00\ \text{kV} + 1.00\ \text{kV}}\right)(12\ \mu\text{F}) = \boxed{4.0\ \mu\text{F}}$$

(*b*) The energy dissipated when the connections are made is the difference between the initial and final energies stored by the system:

$$U_{\text{dissipated}} = U_i - U_f \qquad (1)$$

U_i and U_f are given by:

$$U_i = \tfrac{1}{2}C_1V_i^2 + \tfrac{1}{2}C_2V_i^2 = \tfrac{1}{2}(C_1 + C_2)V_i^2$$

and

$$U_f = \tfrac{1}{2}C_{eq}V_f^2$$

Because C_1 and C_2 are in parallel:

$$C_{eq} = C_1 + C_2$$

Substituting for C_{eq} yields:

$$U_f = \tfrac{1}{2}(C_1 + C_2)V_f^2$$

Substitute for U_i and U_f in equation (1) to obtain:

$$U_{\text{dissipated}} = \tfrac{1}{2}(C_1 + C_2)V_i^2 - \tfrac{1}{2}(C_1 + C_2)V_f^2 = \tfrac{1}{2}(C_1 + C_2)(V_i^2 - V_f^2)$$

Substitute numerical values and evaluate $U_{\text{dissipated}}$:

$$U_{\text{dissipated}} = \tfrac{1}{2}(12\,\mu\text{F} + 4.0\,\mu\text{F})\left[(2.00\,\text{kV})^2 - (1.00\,\text{kV})^2\right] = \boxed{24\,\text{J}}$$

57 •• Two capacitors, one that has a capacitance of 4.00 μF and one that has a capacitance of 12.0 μF, are connected in parallel. The parallel combination is then connected across the terminals of a 12.0-V battery. Next they are carefully disconnected so that they are not discharged. They are then reconnected to each other—the positive plate of each capacitor connected to the negative plate of the other. (*a*) Find the potential difference across each capacitor after they are reconnected. (*b*) Find the energy stored in the capacitors before they are disconnected from the battery, and find the energy stored after they are reconnected.

Picture the Problem When the capacitors are reconnected, each will have a charge equal to the difference between the charges they acquired while they were connected in parallel across the 12.0-V battery. We can use the definition of capacitance and their equivalent capacitance to find the common potential difference across them. In Part (*b*) we can use $U = \frac{1}{2}CV^2$ to find the initial and final energy stored in the capacitors.

(*a*) Using the definition of capacitance, express the potential difference across the capacitors when they are reconnected:

$$V_{\text{f}} = V_{4.00} = V_{12.0} = \frac{Q_{\text{f}}}{C_{\text{eq}}} = \frac{Q_{\text{f}}}{C_1 + C_2} \quad (1)$$

where Q_{f} is the common charge on the capacitors *after* they are reconnected.

Express the final charge Q_{f} on each capacitor:

$$Q_{\text{f}} = Q_2 - Q_1$$

Use the definition of capacitance to substitute for Q_2 and Q_1:

$$Q_{\text{f}} = C_2V - C_1V = (C_2 - C_1)V$$

Substitute in equation (1) to obtain:

$$V_{\text{f}} = \frac{C_2 - C_1}{C_1 + C_2}V$$

Substitute numerical values and evaluate V_{f}:

$$V_{\text{f}} = V_{4.00} = V_{12.0} = \frac{12.0\,\mu\text{F} - 4.00\,\mu\text{F}}{12.0\,\mu\text{F} + 4.00\,\mu\text{F}}(12.0\,\text{V}) = \boxed{6.0\,\text{V}}$$

(*b*) The energy stored in the capacitors initially is given by:

$$U_i = \tfrac{1}{2}C_1V^2 + \tfrac{1}{2}C_2V^2 = \tfrac{1}{2}V^2(C_1 + C_2)$$

Substitute numerical values and evaluate U_i:

$$U_i = \tfrac{1}{2}(12.0\,\text{V})^2(12.0\,\mu\text{F} + 4.00\,\mu\text{F}) = \boxed{1.15\,\text{mJ}}$$

The energy stored in the capacitors when they have been reconnected is given by:

$$U_f = \tfrac{1}{2}C_1V_f^2 + \tfrac{1}{2}C_2V_f^2 = \tfrac{1}{2}V_f^2(C_1 + C_2)$$

Substitute numerical values and evaluate U_f:

$$U_f = \tfrac{1}{2}(6.0\,\text{V})^2(12.0\,\mu\text{F} + 4.00\,\mu\text{F}) = \boxed{0.29\,\text{mJ}}$$

58 •• A 20-pF capacitor is charged to 3.0 kV and then removed from the battery and connected to an uncharged 50-pF capacitor. (*a*) What is the new charge on each capacitor? (*b*) Find the energy stored in the 20-pF capacitor before it is disconnected from the battery, and the energy stored in the two capacitors after they are connected to each other. Does the stored energy increase or decrease when the two capacitors are connected to each other?

Picture the Problem Let the numeral 1 refer to the 20-pF capacitor and the numeral 2 to the 50-pF capacitor. We can use conservation of charge and the fact that the connected capacitors will have the same potential difference across them to find the charge on each capacitor. We can decide whether stored energy increases or decreases when the two capacitors are connected by calculating the change in the electrostatic energy during this process.

(*a*) The final charges on the capacitors are given by:

$$Q_{1f} = C_1V_f \qquad (1)$$

and

$$Q_{2f} = C_2V_f \qquad (2)$$

Using the fact that charge is conserved when the capacitors are connected, relate the charge Q_{1i} initially on the 20-pF capacitor to the charges on the two capacitors when they have been connected:

$$Q_{1i} = Q_{1f} + Q_{2f}$$

or

$$C_1V_{1i} = C_1V_f + C_2V_f$$

Solving for V_f yields:

$$V_f = \frac{C_1}{C_1 + C_2}V_{1i}$$

Substitute for V_f in equations (1) and (2) to obtain:

$$Q_{1f} = \frac{C_1^2}{C_1 + C_2} V_{1i}$$

and

$$Q_{2f} = \frac{C_1 C_2}{C_1 + C_2} V_{1i}$$

Substitute numerical values and evaluate Q_{1f}:

$$Q_{1f} = \left(\frac{(20\text{ pF})^2}{20\text{ pF} + 50\text{ pF}}\right)(3.0\text{ kV}) = 17.1\text{ nC} = \boxed{17\text{ nC}}$$

Substitute numerical values and evaluate Q_{2f}:

$$Q_{2f} = \left(\frac{(20\text{ pF})(50\text{ pF})}{20\text{ pF} + 50\text{ pF}}\right)(3.0\text{ kV}) = 42.9\text{ nC} = \boxed{43\text{ nC}}$$

(*b*) The energy stored in the 20-pF capacitor before it is disconnected from the battery is given by:

$$U_i = U_{1i} = \tfrac{1}{2} C_1 V_{1i}^2 = \tfrac{1}{2}(20\text{ pF})(3.0\text{ kV})^2 = \boxed{90\ \mu\text{J}}$$

The energy stored in the two capacitors after they are connected to each other is given by:

$$U_f = U_{1f} + U_{2f} = \frac{Q_{1f}^2}{2C_1} + \frac{Q_{2f}^2}{2C_2}$$

Substitute numerical values and evaluate U_f:

$$U_f = \frac{(17.1\text{ nC})^2}{2(20\text{ pF})} + \frac{(42.9\text{ nC})^2}{2(50\text{ pF})} = \boxed{26\ \mu\text{J}}$$

Because $U_f < U_i$, the stored energy decreases when the two capacitors are connected.

59 •• [SSM] Capacitors 1, 2 and 3, have capacitances equal to 2.00 μF, 4.00 μF, and 6.00 μF, respectively. The capacitors are connected in parallel, and the parallel combination is connected across the terminals of a 200-V source. The capacitors are then disconnected from both the voltage source and each other, and are connected to three switches as shown in Figure 24-42. (*a*) What is the potential difference across each capacitor when switches S_1 and S_2 are closed but switch S_3 remains open? (*b*) After switch S_3 is closed, what is the final charge on the leftmost plate of each capacitor? (*c*) Give the final potential difference across each capacitor after switch S_3 is closed.

Picture the Problem Let lower case *q*s refer to the charges before S_3 is closed and upper case *Q*s refer to the charges after this switch is closed. We can use conservation of charge to relate the charges on the capacitors before S_3 is closed

to their charges when this switch is closed. We also know that the sum of the potential differences around the circuit when S_3 is closed must be zero and can use this to obtain a fourth equation relating the charges on the capacitors after the switch is closed to their capacitances. Solving these equations simultaneously will yield the charges Q_1, Q_2, and Q_3. Knowing these charges, we can use the definition of capacitance to find the potential difference across each of the capacitors.

(*a*) With S_1 and S_2 closed, but S_3 open, the charges on and the potential differences across the capacitors do not change. Hence:

$$V_1 = V_2 = V_3 = \boxed{200\,\text{V}}$$

(*b*) When S_3 is closed, the charges can redistribute; express the conditions on the charges that must be satisfied as a result of this redistribution:

$q_2 - q_1 = Q_2 - Q_1$,
$q_3 - q_2 = Q_3 - Q_2$,
and
$q_1 - q_3 = Q_1 - Q_3$.

Express the condition on the potential differences that must be satisfied when S_3 is closed:

$V_1 + V_2 + V_3 = 0$
where the subscripts refer to the three capacitors.

Use the definition of capacitance to eliminate the potential differences:

$$\frac{Q_1}{C_1} + \frac{Q_2}{C_2} + \frac{Q_3}{C_3} = 0 \qquad (1)$$

Use the definition of capacitance to find the initial charge on each capacitor:

$q_1 = C_1V = (2.00\,\mu\text{F})(200\,\text{V}) = 400\,\mu\text{C}$,
$q_2 = C_2V = (4.00\,\mu\text{F})(200\,\text{V}) = 800\,\mu\text{C}$,
and
$q_3 = C_3V = (6.00\,\mu\text{F})(200\,\text{V}) = 1200\,\mu\text{C}$

Let $q = q_1$. Then:

$q_2 = 2Q$ and $q_3 = 3Q$

Express Q_2 and Q_3 in terms of Q_1 and Q:

$$Q_2 = Q + Q_1 \qquad (2)$$
and
$$Q_3 = Q_1 + 2Q \qquad (3)$$

Substitute in equation (1) to obtain:

$$\frac{Q_1}{C_1}+\frac{Q+Q_1}{C_2}+\frac{Q_1+2Q}{C_3}=0$$

or

$$\frac{Q_1}{2.00\,\mu\text{F}}+\frac{Q+Q_1}{4.00\,\mu\text{F}}+\frac{Q_1+2Q}{6.00\,\mu\text{F}}=0$$

Solve for and evaluate Q_1 to obtain:

$$Q_1=-\tfrac{7}{11}Q=-\tfrac{7}{11}(400\,\mu\text{C})=\boxed{-255\,\mu\text{C}}$$

Substitute in equation (2) to obtain:

$$Q_2=400\,\mu\text{C}-255\,\mu\text{C}=\boxed{145\,\mu\text{C}}$$

Substitute in equation (3) to obtain:

$$Q_3=-255\,\mu\text{C}+2(400\,\mu\text{C})=\boxed{545\,\mu\text{C}}$$

(*c*) Use the definition of capacitance to find the potential difference across each capacitor with S_3 closed:

$$V_1=\frac{Q_1}{C_1}=\frac{-255\,\mu\text{C}}{2.00\,\mu\text{F}}=\boxed{-127\,\text{V}},$$

$$V_2=\frac{Q_2}{C_2}=\frac{145\,\mu\text{C}}{4.00\,\mu\text{F}}=\boxed{36.3\,\text{V}},$$

and

$$V_3=\frac{Q_3}{C_3}=\frac{545\,\mu\text{C}}{6.00\,\mu\text{F}}=\boxed{90.8\,\text{V}}$$

60 •• A capacitor has a capacitance *C* and a charge *Q* on its positively charged plate. A student connects one terminal of the capacitor to a terminal of an identical capacitor whose plates are electrically neutral. When the remaining two terminals are connected, charge flows until electrostatic equilibrium is reestablished and both capacitors have charge *Q*/2 on them. Compare the total energy initially stored in the one capacitor to the total energy stored in the two when electrostatic equilibrium is reestablished. If there is less energy afterward, where do you think the missing energy went? *Hint: Wires that transport charge can heat up, which is called Joule heating and is discussed in detail in Chapter 25.*

Picture the Problem We can use the expression for the energy stored in a capacitor to express the ratio of the energy stored in the system after the discharge of the first capacitor to the energy stored in the system prior to the discharge.

Express the energy *U* initially stored in the capacitor whose capacitance is *C*:

$$U=\frac{Q^2}{2C}$$

The energy U' stored in the two capacitors after the first capacitor has discharged is:

$$U' = \frac{\left(\frac{Q}{2}\right)^2}{2C} + \frac{\left(\frac{Q}{2}\right)^2}{2C} = \frac{Q^2}{4C}$$

Express the ratio of U' to U:

$$\frac{U'}{U} = \frac{\frac{Q^2}{4C}}{\frac{Q^2}{2C}} = \frac{1}{2} \Rightarrow U' = \boxed{\tfrac{1}{2}U}$$

The missing energy was converted into thermal energy by the resistance of the connecting wires.

Dielectrics

61 • You are a laboratory assistant in a physics department that has budget problems. Your supervisor wants to construct cheap parallel-plate capacitors for use in introductory laboratory experiments. The design uses polyethylene, which has a dielectric constant of 2.30, between two sheets of aluminum foil. The area of each sheet of foil is 400 cm^2 and the thickness of the polyethylene is 0.300 mm. Find the capacitance of this arrangement.

Picture the Problem The capacitance of a parallel-plate capacitor filled with a dielectric of constant κ is given by $C = \frac{\kappa \in_0 A}{d}$.

Relate the capacitance of the parallel-plate capacitor to the area of its plates, their separation, and the dielectric constant of the material between the plates:

$$C = \frac{\kappa \in_0 A}{d}$$

Substitute numerical values and evaluate C:

$$C = \frac{(2.30)\left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(400\,\text{cm}^2\right)}{0.300\,\text{mm}} = \boxed{2.72\,\text{nF}}$$

62 •• The radius and the length of the central wire in a Geiger tube are 0.200 mm and 12.0 cm, respectively. The outer surface of the tube is a conducing cylindrical shell that has an inner radius of 1.50 cm. The shell is coaxial with the wire and has the same length (12.0 cm).The tube is filled with a gas that has a dielectric constant of 1.08 and a dielectric strength of 2.00×10^6 V/m. (*a*) What is

the maximum potential difference that can be maintained between the wire and shell? (*b*) What is the maximum charge per unit length on the wire?

Picture the Problem The capacitance of a cylindrical capacitor is given by $C = 2\pi\kappa \in_0 L/\ln(r_2/r_1)$, where L is its length and r_1 and r_2 the radii of the inner and outer conductors. We can use this expression, in conjunction with the definition of capacitance, to express the potential difference between the wire and the cylindrical shell in the Geiger tube. Because the electric field E in the tube is related to the linear charge density λ on the wire according to $E = 2k\lambda/\kappa r$, we can use this expression to find $2k\lambda/\kappa$ for $E = E_{max}$. In Part (*b*) we'll use this relationship to find the charge per unit length λ on the wire.

(*a*) Use the definition of capacitance and the expression for the capacitance of a cylindrical capacitor to express the potential difference between the wire and the cylindrical shell in the tube:

$$\Delta V = \frac{Q}{C} = \frac{Q}{\dfrac{2\pi\kappa \in_0 L}{\ln(R/r)}} = \frac{2\lambda}{4\pi \in_0 \kappa}\ln\left(\frac{R}{r}\right) = \frac{2k\lambda}{\kappa}\ln\left(\frac{R}{r}\right)$$

where λ is the linear charge density, κ is the dielectric constant of the gas in the Geiger tube, r is the radius of the wire, and R the radius of the coaxial cylindrical shell of length L.

Express the electric field at a distance r greater than its radius from the center of the wire:

$$E = \frac{2k\lambda}{\kappa r} \Rightarrow \frac{2k\lambda}{\kappa} = Er \qquad (1)$$

Substituting for $\dfrac{2k\lambda}{\kappa}$ yields:

$$\Delta V = Er\ln\left(\frac{R}{r}\right)$$

Noting that E is a maximum at $r = 0.200$ mm, substitute numerical values and evaluate ΔV_{max}:

$$\Delta V_{max} = (2.00\times10^6\ \text{V/m})(0.200\,\text{mm})\ln\left(\frac{1.50\,\text{cm}}{0.200\,\text{mm}}\right) = \boxed{1.73\,\text{kV}}$$

(*b*) Solve equation (1) for λ:

$$\lambda = \frac{E_{max}\kappa r}{2k}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{(1.08)(2.00\times10^6\ \text{V/m})(0.200\,\text{mm})}{2(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2)} = \boxed{24.0\,\text{nC/m}}$$

63 •• You are a materials science engineer and your group has fabricated a new dielectric, that has an exceptionally large dielectric constant of 24 and a dielectric strength of 4.0×10^7 V/m. Suppose you want to use this material to construct a 0.10-μF parallel plate capacitor that can withstand a potential difference of 2.0 kV. (*a*) What is the minimum plate separation required to do this? (*b*) What is the area of each plate at this separation?

Picture the Problem We can use the relationship between the electric field between the plates of a capacitor, their separation, and the potential difference between them to find the minimum plate separation. We can use the expression for the capacitance of a dielectric-filled parallel-plate capacitor to determine the necessary area of the plates.

(*a*) Relate the electric field of the capacitor to the potential difference across its plates:

$$E = \frac{V}{d} \Rightarrow d = \frac{V}{E}$$

where d is the plate separation.

Noting that d_{min} corresponds to E_{max}, evaluate d_{min}:

$$d_{\text{min}} = \frac{V}{E_{\text{max}}} = \frac{2000\,\text{V}}{4.0\times10^7\ \text{V/m}} = \boxed{50\,\mu\text{m}}$$

(*b*) Relate the capacitance of a parallel-plate capacitor to the area of its plates:

$$C = \frac{\kappa \in_0 A}{d} \Rightarrow A = \frac{Cd}{\kappa \in_0}$$

Substitute numerical values and evaluate A:

$$A = \frac{(0.10\,\mu\text{F})(50\,\mu\text{m})}{24(8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2)} = 2.35\times10^{-2}\ \text{m}^2 = \boxed{240\,\text{cm}^2}$$

64 •• A parallel-plate capacitor has plates separated by a distance d. The capacitance of this capacitor is C_0 when no dielectric is in the space between the plates. However, the space between the plates is completely filled by two different dielectrics. One dielectric has a thickness $\frac{1}{4}d$ and a dielectric constant κ_1, and the other dielectric has a thickness $\frac{3}{4}d$ and a dielectric constant κ_2. Find the capacitance of this capacitor.

Picture the Problem We can model this system as two capacitors in series, one of thickness $\frac{1}{4}d$ and the other of thickness $\frac{3}{4}d$ and use the equation for the equivalent capacitance of two capacitors connected in series. Let the capacitance of the capacitor whose dielectric constant is κ_1 be C_1 and the capacitance of the capacitor whose dielectric constant is κ_2 be C_2.

Express the equivalent capacitance of the two capacitors connected in series:

$$\frac{1}{C_{\text{eq}}}=\frac{1}{C_1}+\frac{1}{C_2}\Rightarrow C_{\text{eq}}=\frac{C_1C_2}{C_1+C_2}$$

Relate the capacitance of C_1 to its dielectric constant and thickness:

$$C_1=\frac{\kappa_1 \epsilon_0 A}{\frac{1}{4}d}=\frac{4\kappa_1 \epsilon_0 A}{d}$$

Relate the capacitance of C_2 to its dielectric constant and thickness:

$$C_2=\frac{\kappa_2 \epsilon_0 A}{\frac{3}{4}d}=\frac{4\kappa_2 \epsilon_0 A}{3d}$$

Substitute for C_1 and C_2 and simplify to obtain:

$$C_{\text{eq}}=\frac{\left(\frac{4\kappa_1 \epsilon_0 A}{d}\right)\left(\frac{4\kappa_2 \epsilon_0 A}{3d}\right)}{\frac{4\kappa_1 \epsilon_0 A}{d}+\frac{4\kappa_2 \epsilon_0 A}{3d}}=\frac{\left(\frac{\kappa_1}{d}\right)\left(\frac{4\kappa_2}{3d}\right)}{\frac{3\kappa_1}{3d}+\frac{\kappa_2}{3d}}\epsilon_0 A=\frac{\frac{4\kappa_1\kappa_2}{d}}{3\kappa_1+\kappa_2}\epsilon_0 A$$

$$=\frac{4\kappa_1\kappa_2}{3\kappa_1+\kappa_2}\left(\frac{\epsilon_0 A}{d}\right)=\boxed{\left(\frac{4\kappa_1\kappa_2}{3\kappa_1+\kappa_2}\right)C_0}$$

65 •• Two capacitors each have two conducting plates of surface area A and an air gap of width d. They are connected in parallel, as shown in Figure 24-43 and each has a charge Q on the positively charged plate. A slab that has a width d, an area A, and a dielectric constant κ is inserted between the plates of *one* of the capacitors. Calculate the new charge Q' on the positively charged plate of that capacitor after electrostatic equilibrium is re-established.

Picture the Problem Let the charge on the capacitor with the air gap be Q_1 and the charge on the capacitor with the dielectric gap be Q_2. If the capacitances of the capacitors were initially C, then the capacitance of the capacitor with the dielectric inserted is $C' = \kappa C$. We can use the conservation of charge and the equivalence of the potential difference across the capacitors to obtain two equations that we can solve simultaneously for Q_1 and Q_2.

Apply conservation of charge during the insertion of the dielectric to obtain:

$$Q_1 + Q_2 = 2Q \qquad (1)$$

Because the capacitors have the same potential difference across them:

$$\frac{Q_1}{C} = \frac{Q_2}{\kappa C} \qquad (2)$$

Solve equations (1) and (2) simultaneously to obtain:

$$Q_1 = \boxed{\frac{2Q}{1+\kappa}} \text{ and } Q_2 = \boxed{\frac{2Q\kappa}{1+\kappa}}$$

66 •• A parallel-plate capacitor has a plate separation d has a capacitance equal to C_0 where there is only empty space in the space between the plates. A slab of thickness t, where $t < d$, that has a dielectric constant κ is placed in the space between the plates completely covering one of the plates. What is the capacitance with the slab inserted?

Picture the Problem We can model this system as two capacitors in series, C_1 of thickness t and C_2 of thickness $d - t$ and use the equation for the equivalent capacitance of two capacitors connected in series.

Express the equivalent capacitance of the two capacitors connected in series:

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} \text{ or } C_{\text{eq}} = \frac{C_1 C_2}{C_1 + C_2}$$

Relate the capacitance of C_1 to its dielectric constant and thickness:

$$C_1 = \frac{\kappa \in_0 A}{t}$$

Relate the capacitance of C_2 to its dielectric constant and thickness:

$$C_2 = \frac{\in_0 A}{d-t}$$

Substitute for C_1 and C_2 and simplify to obtain:

$$C_{\text{eq}} = \frac{\left(\frac{\kappa \in_0 A}{t}\right)\left(\frac{\in_0 A}{d-t}\right)}{\frac{\kappa \in_0 A}{t} + \frac{\in_0 A}{d-t}} = \frac{\left(\frac{\kappa}{t}\right)\left(\frac{1}{d-t}\right)}{\frac{\kappa}{t} + \frac{1}{d-t}} \in_0 A = \frac{\left(\frac{\kappa}{t}\right)\left(\frac{1}{d-t}\right)}{\frac{\kappa}{t} + \frac{1}{d-t}} \in_0 A$$

$$= \frac{\kappa}{\kappa(d-t)+t} \in_0 A = \boxed{\left(\frac{\kappa d}{\kappa(d-t)+t}\right) C_0}$$

67 •• The membrane of the axon of a nerve cell can be modeled as a thin cylindrical shell of radius 1.00×10^{-5} m, having a length of 10.0 cm and a thickness of 10.0 nm. The membrane has a positive charge on one side and a negative charge on the other, and the membrane acts as a parallel-plate capacitor of area $2\pi rL$ and separation d. Assume the membrane is filled with a material whose dielectric constant is 3.00. (*a*) Find the capacitance of the membrane. If the potential difference across the membrane is 70.0 mV, find (*b*) the charge on the positively charged side of the membrane.

Picture the Problem Because $d << r$, we can model the membrane as a parallel-plate capacitor. We can use the definition of capacitance to find the charge on each side of the membrane in Part (*b*).

(*a*) Express the capacitance of a parallel-plate capacitor:

$$C = \frac{\kappa \in_0 A}{d}$$

Substitute for the area of the plates:

$$C = \frac{2\pi\kappa \in_0 rL}{d} = \frac{\kappa rL}{2kd}$$

Substitute numerical values and evaluate C:

$$C = \frac{(3.00)(1.00\times10^{-5}\text{ m})(0.100\text{ m})}{2(8.988\times10^{9}\text{ N}\cdot\text{m}^2/\text{C}^2)(10.0\text{ nm})}$$
$$= 16.69\text{ nF} = \boxed{16.7\text{ nF}}$$

(*b*) Use the definition of capacitance to find the charge on each side of the membrane:

$$Q = CV = (16.69\text{nF})(70.0\text{mV})$$
$$= \boxed{1.17\text{nC}}$$

68 •• The space between the plates of the capacitor that is connected across the terminals of a battery is filled with a dielectric material. Determine the dielectric constant of the material if the induced bound–charge-per-unit-area on it is (*a*) 80 percent of the free–charge-per-unit-area on the plates, (*b*) 20 percent of the free–charge-per-unit-area on the plates, and (*c*) 98 percent of the free–charge-per-unit-area on the plates.

Picture the Problem The bound charge density is related to the dielectric constant and the free charge density by the equation $\sigma_b = \left(1 - \frac{1}{\kappa}\right)\sigma_f$.

Solve the equation relating σ_b, σ_f, and κ for κ to obtain:

$$\kappa = \frac{1}{1 - \sigma_b/\sigma_f}$$

(a) Evaluate this expression for $\sigma_b/\sigma_f = 0.80$:

$$\kappa = \frac{1}{1-0.80} = \boxed{5.0}$$

(b) Evaluate this expression for $\sigma_b/\sigma_f = 0.20$:

$$\kappa = \frac{1}{1-0.20} = \boxed{1.3}$$

(c) Evaluate this expression for $\sigma_b/\sigma_f = 0.98$:

$$\kappa = \frac{1}{1-0.98} = \boxed{50}$$

69 •• The positively charge plate of a parallel-plate capacitor has a charge equal to Q. When the space between the plates is evacuated of air, the electric field strength between the plates is 2.5×10^5 V/m. When the space is filled with a certain dielectric material, the field strength between the plates is reduced to 1.2×10^5 V/m. (a) What is the dielectric constant of the material? (b) If $Q = 10$ nC, what is the area of the plates? (c) What is the total induced bound charge on either face of the dielectric material?

Picture the Problem We can use the definition of the dielectric constant to find its value. In Part (b) we can use the expression for the electric field in the space between the charged capacitor plates to find the area of the plates and in Part (c) we can relate the surface charge densities to the induced charges on the plates.

(a) Using the definition of the dielectric constant, relate the electric field without a dielectric E_0 to the field with a dielectric E:

$$E = \frac{E_0}{\kappa} \Rightarrow \kappa = \frac{E_0}{E}$$

Solve for and evaluate κ:

$$\kappa = \frac{2.5\times10^5\ \text{V/m}}{1.2\times10^5\ \text{V/m}} = 2.08 = \boxed{2.1}$$

(b) Relate the electric field in the region between the plates to the surface charge density of the plates:

$$E_0 = \frac{\sigma}{\epsilon_0} = \frac{Q/A}{\epsilon_0} \Rightarrow A = \frac{Q}{E_0\,\epsilon_0}$$

Substitute numerical values and evaluate A:

$$A = \frac{10\,\text{nC}}{\left(2.5\times10^5\ \text{V/m}\right)\left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)}$$

$$= 4.52\times10^{-3}\ \text{m}^2 = \boxed{45\,\text{cm}^2}$$

(*c*) Relate the surface charge densities to the induced charges on the plates:

$$\sigma_b = \left(1 - \frac{1}{\kappa}\right)\sigma_f$$

or

$$\frac{\sigma_b}{\sigma_f} = \frac{Q_b}{Q_f} = 1 - \frac{1}{\kappa} \Rightarrow Q_b = \left(1 - \frac{1}{\kappa}\right)Q_f$$

Substitute numerical values and evaluate Q_b:

$$Q_b = \left(1 - \frac{1}{2.08}\right)(10\,\text{nC}) = \boxed{5.2\,\text{nC}}$$

70 •• Find the capacitance of the parallel-plate capacitor shown in Figure 24-44.

Picture the Problem We can model this parallel-plate capacitor as a combination of two capacitors C_1 and C_2 in series with capacitor C_3 in parallel.

Express the capacitance of two series-connected capacitors in parallel with a third:

$$C = C_3 + C_s \qquad (1)$$

where

$$C_s = \frac{C_1 C_2}{C_1 + C_2} \qquad (2)$$

Express each of the capacitances C_1, C_2, and C_3 in terms of the dielectric constants, plate areas, and plate separations:

$$C_1 = \frac{\kappa_1 \in_0 \left(\frac{1}{2}A\right)}{\frac{1}{2}d} = \frac{\kappa_1 \in_0 A}{d},$$

$$C_2 = \frac{\kappa_2 \in_0 \left(\frac{1}{2}A\right)}{\frac{1}{2}d} = \frac{\kappa_2 \in_0 A}{d},$$

and

$$C_3 = \frac{\kappa_3 \in_0 \left(\frac{1}{2}A\right)}{d} = \frac{\kappa_3 \in_0 A}{2d}$$

Substitute in equation (2) to obtain:

$$C_s = \frac{\left(\frac{\kappa_1 \in_0 A}{d}\right)\left(\frac{\kappa_2 \in_0 A}{d}\right)}{\frac{\kappa_1 \in_0 A}{d} + \frac{\kappa_2 \in_0 A}{d}} = \frac{\kappa_1 \kappa_2}{\kappa_1 + \kappa_2}\left(\frac{\in_0 A}{d}\right)$$

Substitute in equation (1) to obtain:

$$C = \frac{\kappa_3 \in_0 A}{2d} + \frac{\kappa_1 \kappa_2}{\kappa_1 + \kappa_2}\left(\frac{\in_0 A}{d}\right) = \boxed{\left(\kappa_3 + \frac{2\kappa_1 \kappa_2}{\kappa_1 + \kappa_2}\right)\left(\frac{\in_0 A}{2d}\right)}$$

General Problems

71 • You are given four identical capacitors and a 100-V battery. When only one of the capacitors is connected to this battery the energy stored is U_0. Combine the four capacitors in such a way that the total energy stored in all four capacitors is U_0? Describe the combination and explain your answer.

Picture the Problem We can use the expression $U_0 = \frac{1}{2}C_{eq}V^2$ to express the total energy stored in the combination of four capacitors in terms of their equivalent capacitance C_{eq}.

The energy stored in one capacitor when it is connected to the 100-V battery is:

$$U_0 = \tfrac{1}{2}CV^2$$

When the four capacitors are connected to the battery in some combination, the total energy stored in them is:

$$U = \tfrac{1}{2}C_{eq}V^2$$

Equate U and U_0 and solve for C_{eq}:

$$\tfrac{1}{2}C_{eq}V^2 = \tfrac{1}{2}CV^2 \Rightarrow C_{eq} = C$$

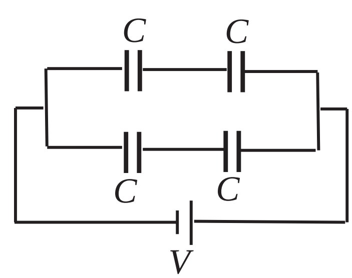
The equivalent capacitance C' of two capacitors of capacitance C connected in series is their product divided by their sum:

$$C' = \frac{C^2}{C+C} = \tfrac{1}{2}C$$

If we connect two of the capacitors in series in parallel with the other two capacitors connected in series, their equivalent capacitance will be:

$$C_{eq} = C' + C' = \tfrac{1}{2}C + \tfrac{1}{2}C = C$$

A series combination of two of the capacitors connected in parallel with a series combination of the other two capacitors will result in total energy U_0 stored in all four capacitors. The circuit diagram is shown to the right.



72 • Three capacitors have capacitances of 2.00 μF, 4.00 μF, and 8.00 μF. Find the equivalent capacitance if (*a*) the capacitors are connected in parallel and (*b*) if the capacitors are connected in series.

Picture the Problem We can use the equations for the equivalent capacitance of three capacitors connected in parallel and in series to find these equivalent capacitances.

(*a*) Express the equivalent capacitance of three capacitors connected in parallel:

$$C_{\text{eq}} = C_1 + C_2 + C_3$$

Substitute numerical values and evaluate C_{eq}:

$$C_{\text{eq}} = 2.00\,\mu\text{F} + 4.00\,\mu\text{F} + 8.00\,\mu\text{F} = \boxed{14.00\,\mu\text{F}}$$

(*b*) The equivalent capacitance of the three capacitors connected in series is given by:

$$C_{\text{eq}} = \frac{C_1C_2C_3}{C_1C_2 + C_2C_3 + C_1C_3}$$

Substitute numerical values and evaluate C_{eq}:

$$C_{\text{eq}} = \frac{(2.00\,\mu\text{F})(4.00\,\mu\text{F})(8.00\,\mu\text{F})}{(2.00\,\mu\text{F})(4.00\,\mu\text{F}) + (4.00\,\mu\text{F})(8.00\,\mu\text{F}) + (2.00\,\mu\text{F})(8.00\,\mu\text{F})} = \boxed{1.14\,\mu\text{F}}$$

73 • A 1.00-μF capacitor is connected in parallel with a 2.00-μF capacitor, and this combination is connected in series with a 6.00-μF capacitor. What is the equivalent capacitance of this combination?

Picture the Problem We can first use the equation for the equivalent capacitance of two capacitors connected in parallel and then the equation for two capacitors connected in series to find the equivalent capacitance.

Find the equivalent capacitance of a 1.00-μF capacitor connected in parallel with a 2.00-μF capacitor:

$$C_{\text{eq},1} = C_1 + C_2 = 1.00\,\mu\text{F} + 2.00\,\mu\text{F} = 3.00\,\mu\text{F}$$

Find the equivalent capacitance of a 3.00-μF capacitor connected in series with a 6.00-μF capacitor:

$$C_{\text{eq},2} = \frac{C_{\text{eq},1}C_6}{C_{\text{eq},1} + C_6} = \frac{(3.00\,\mu\text{F})(6.00\,\mu\text{F})}{3.00\,\mu\text{F} + 6.00\,\mu\text{F}} = \boxed{2.00\,\mu\text{F}}$$

74 • The voltage across a parallel-plate capacitor that has a plate separation equal to 0.500 mm is 1.20 kV. The capacitor is disconnected from the voltage source and the separation between the plates is increased until the energy stored in the capacitor has been doubled. Determine the final separation between the plates.

Picture the Problem The charge Q and the charge density σ are independent of the separation of the plates and do not change during the process described in the problem statement. Because the electric field E depends on σ, it too is constant. We can use $U = \frac{1}{2}CV^2$ and the relationship between V and E, together with the expression for the capacitance of a parallel-plate capacitor, to show that $U \propto d$.

Express the energy stored in the capacitor in terms of its capacitance C and the potential difference across its plates:

$$U = \tfrac{1}{2}CV^2 \qquad (1)$$

Express V in terms of E:

$$V = Ed$$

where d is the separation of the plates.

Express the capacitance of a parallel-plate capacitor:

$$C = \frac{\kappa \in_0 A}{d}$$

Substitute for C and V in equation (1) to obtain:

$$U = \tfrac{1}{2}\frac{\kappa \in_0 A}{d}(Ed)^2 = \left(\tfrac{1}{2}\kappa \in_0 AE^2\right)d$$

Because $U \propto d$, to double U one must double d. Hence:

$$d_{\text{f}} = 2d = 2(0.500\,\text{mm}) = \boxed{1.00\,\text{mm}}$$

75 •• Determine the equivalent capacitance, in terms of C_0, of each of the combinations of capacitors shown in Figure 24-45.

Picture the Problem We can use the equations for the equivalent capacitance of capacitors connected in parallel and in series to find the single capacitor that will store the same amount of charge as each of the networks shown above.

(*a*) Find the capacitance of the two capacitors in parallel:

$$C_{\text{eq,1}} = C_0 + C_0 = 2C_0$$

Find the capacitance equivalent to $2C_0$ in series with C_0:

$$C_{\text{eq,2}} = \frac{C_{\text{eq,1}}C_0}{C_{\text{eq,1}} + C_0} = \frac{(2C_0)C_0}{2C_0 + C_0} = \boxed{\tfrac{2}{3}C_0}$$

(*b*) Find the capacitance of two capacitors of capacitance C_0 in parallel:

$$C_{\text{eq},1} = 2C_0$$

Find the capacitance equivalent to $2C_0$ in series with $2C_0$:

$$C_{\text{eq},2} = \frac{C_{\text{eq},1}C_0}{C_{\text{eq},1} + C_0} = \frac{(2C_0)(2C_0)}{2C_0 + 2C_0} = \boxed{C_0}$$

(*c*) Find the equivalent capacitance of three equal capacitors connected in parallel:

$$C_{\text{eq}} = C_0 + C_0 + C_0 = \boxed{3C_0}$$

76 •• Figure 24-46 shows four capacitors connected in the arrangement known as a capacitance bridge. The capacitors are initially uncharged. What must the relation between the four capacitances be so that the potential difference between points *c* and *d* remains zero when a voltage *V* is applied between points *a* and *b*?

Picture the Problem Note that with *V* applied between *a* and *b*, C_1 and C_3 are in series, and so are C_2 and C_4. Because in a series combination the potential differences across the two capacitors are inversely proportional to the capacitances, we can establish proportions involving the capacitances and potential differences for the left- and right-hand side of the network and then use the condition that $V_c = V_d$ to eliminate the potential differences and establish the relationship between the capacitances.

Letting *Q* represent the charge on capacitors 1 and 2, relate the potential differences across the capacitors to their common charge and capacitances:

$$V_1 = \frac{Q}{C_1} \text{ and } V_3 = \frac{Q}{C_3}$$

Divide the first of these equations by the second to obtain:

$$\frac{V_1}{V_3} = \frac{C_3}{C_1} \quad (1)$$

Proceed similarly to obtain:

$$\frac{V_2}{V_4} = \frac{C_4}{C_2} \quad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{V_1V_4}{V_3V_2} = \frac{C_3C_2}{C_1C_4} \quad (3)$$

If $V_c = V_d$ then we must have: $V_1 = V_2$ and $V_3 = V_4$

Substitute in equation (3) and rearrange to obtain: $\boxed{C_2C_3 = C_1C_4}$

77 •• The plates of a parallel-plate capacitor are separated by distance *d*, and each plate has area *A*. The capacitor is charged to a potential difference *V* and then disconnected from the voltage source. The plates are then pulled apart until the separation is 3*d*. Find (*a*) the new capacitance, (*b*) the new potential difference, and (*c*) the new stored energy. (*d*) How much work was required to change the plate separation from *d* to 3*d*?

Picture the Problem We can use the expression for the capacitance of a parallel-plate capacitor as a function of *A* and *d* to determine the effect on the capacitance of doubling the plate separation. We can use $V = Ed$ to determine the effect on the potential difference across the capacitor of doubling the plate separation. Finally, we can use $U = \frac{1}{2}CV^2$ to determine the effect of doubling the plate separation on the energy stored in the capacitor.

(*a*) The capacitance of a capacitor whose plates are separated by a distance 3*d* is given by:

$$C_{\text{new}} = \boxed{\frac{\epsilon_0 A}{3d}}$$

(*b*) Express the potential difference across a parallel-plate capacitor whose plates are separated by a distance *d*:

$$V = Ed$$

where the electric field *E* depends solely on the charge on the capacitor plates.

Express the new potential difference across the plates resulting from tripling their separation:

$$V_{\text{new}} = E(3d) = 3(Ed) = \boxed{3V}$$

(*c*) Relate the energy stored in a parallel-plate capacitor to the separation of the plates:

$$U = \frac{1}{2}CV^2 = \frac{1}{2}\frac{\epsilon_0 A}{d}V^2$$

When the plate separation is tripled we have:

$$U_{\text{new}} = \frac{1}{2}\frac{\epsilon_0 A}{3d}(3V)^2 = \boxed{\frac{3\epsilon_0 AV^2}{2d}}$$

(*d*) Relate the work required to change the plate separation from *d* to 3*d* to the change in the electrostatic potential energy of the system:

$$W = U_{\text{new}} - U_{\text{i}} = \frac{3 \in_0 AV^2}{2d} - \frac{1}{2}\frac{\in_0 AV^2}{d} = \boxed{\frac{\in_0 AV^2}{d}}$$

78 •• A parallel-plate capacitor has capacitance C_0 when there is no dielectric in the space between the plates. The space between the plates is then filled with a material that has a dielectric constant of κ. When a second capacitor of capacitance C' is connected in series with the first, the capacitance of the series combination is C_0. Find C' in terms of C_0.

Picture the Problem We can use the equation for the equivalent capacitance of two capacitors in series to relate C_0 to C' and the capacitance of the dielectric-filled parallel-plate capacitor and then solve the resulting equation for C'.

Express the equivalent capacitance of the system in terms of C' and C, where C is the dielectric-filled capacitor:

$$C_0 = \frac{C'C}{C'+C} \Rightarrow C' = \frac{C_0 C}{C - C_0}$$

Express the capacitance of the dielectric-filled capacitor:

$$C = \frac{\kappa \in_0 A}{d} = \kappa C_0$$

Substitute for C in the equation for C' and simplify to obtain:

$$C' = \frac{C_0(\kappa C_0)}{\kappa C_0 - C_0} = \boxed{\frac{\kappa}{\kappa - 1}C_0}$$

79 •• **[SSM]** A parallel combination of two identical 2.00-μF parallel-plate capacitors (no dielectric is in the space between the plates) is connected to a 100-V battery. The battery is then removed and the separation between the plates of one of the capacitors is doubled. Find the charge on the positively charged plate of each of the capacitors.

Picture the Problem When the battery is removed, after having initially charged both capacitors, and the separation of one of the capacitors is doubled, the charge is redistributed subject to the condition that the total charge remains constant; that is, $Q = Q_1 + Q_2$ where Q is the initial charge on both capacitors and Q_2 is the charge on the capacitor whose plate separation has been doubled. We can use the conservation of charge during the plate separation process and the fact that, because the capacitors are in parallel, they share a common potential difference.

Find the equivalent capacitance of the two 2.00-μF parallel-plate capacitors connected in parallel:

$$C_{eq} = 2.00\,\mu\text{F} + 2.00\,\mu\text{F} = 4.00\,\mu\text{F}$$

Use the definition of capacitance to find the charge on the equivalent capacitor:

$$Q = C_{eq}V = (4.00\,\mu\text{F})(100\,\text{V}) = 400\,\mu\text{C}$$

Relate this total charge to charges distributed on capacitors 1 and 2 when the battery is removed and the separation of the plates of capacitor 2 is doubled:

$$Q = Q_1 + Q_2 \qquad (1)$$

Because the capacitors are in parallel:

$$V_1 = V_2 \text{ and } \frac{Q_1}{C_1} = \frac{Q_2}{C_2'} = \frac{Q_2}{\frac{1}{2}C_2} = \frac{2Q_2}{C_2}$$

Solve for Q_1 to obtain:

$$Q_1 = 2\left(\frac{C_1}{C_2}\right)Q_2 \qquad (2)$$

Substitute equation (2) in equation (1) and solve for Q_2 to obtain:

$$Q_2 = \frac{Q}{2(C_1/C_2)+1}$$

Substitute numerical values and evaluate Q_2:

$$Q_2 = \frac{400\,\mu\text{C}}{2(2.00\,\mu\text{F}/2.00\,\mu\text{F})+1} = \boxed{133\,\mu\text{C}}$$

Substitute numerical values in equation (1) or equation (2) and evaluate Q_1:

$$Q_1 = \boxed{267\,\mu\text{C}}$$

80 •• An parallel-plate capacitor with no dielectric in the space between the plates has a capacitance C_0 and a plate separation d. Two dielectric slabs that have dielectric constants of κ_1 and κ_2 respectively are then inserted between the plates as shown in Figure 24-47. Each slab is has a thickness $\frac{1}{2}d$ and has area A, the same area as each capacitor plate. When the charge on the positively charged capacitor plate is Q, find (*a*) the electric field in each dielectric, and (*b*) the potential difference between the plates. (*c*) Show that the capacitance of the system after the slabs are inserted is given by $\left[2\kappa_1\kappa_2/(\kappa_1+\kappa_2)\right]C_o$. (*d*) Show that $\left[2\kappa_1\kappa_2/(\kappa_1+\kappa_2)\right]C_o$ is the equivalent capacitance of a series combination of two capacitors, each having plates of area A and a gap width equal to d/2. The space between the plates of one is filled with a material that has a dielectric constant

equal to κ_1 and the space between the plates of the other is filled with a material that has a dielectric constant equal to κ_2.

Picture the Problem We can relate the electric field in the dielectric to the electric field between the capacitor's plates in the absence of a dielectric using $E = E_0/\kappa$. In Part (*b*) we can express the potential difference between the plates as the sum of the potential differences across the dielectrics and then express the potential differences in terms of the electric fields in the dielectrics. In Part (*c*) we can use our result from (*b*) and the definition of capacitance to express the capacitance of the dielectric-filled capacitor. In Part (*d*) we can confirm the result of Part (*c*) by using the addition formula for capacitors in series.

(*a*) Express the electric field E in a dielectric of constant κ in terms of the electric field E_0 in the absence of the dielectric:

$$E = \frac{E_0}{\kappa}$$

Express the electric field E_0 in the absence of the dielectrics:

$$E_0 = \frac{\sigma}{\epsilon_0} = \frac{Q}{\epsilon_0 A}$$

Substitute for E_0 to obtain:

$$E = \frac{Q}{\kappa \epsilon_0 A}$$

Use this relationship to express the electric fields in dielectrics whose constants are κ_1 and κ_2:

$$E_1 = \boxed{\frac{Q}{\kappa_1 \epsilon_0 A}} \text{ and } E_2 = \boxed{\frac{Q}{\kappa_2 \epsilon_0 A}}$$

(*b*) Express the potential difference between the plates as the sum of the potential differences across the dielectrics:

$$V = V_1 + V_2$$

Relate the potential differences to the electric fields and the thicknesses of the dielectrics:

$$V_1 = E_1 \frac{d}{2} = \frac{Qd}{2\kappa_1 \epsilon_0 A}$$

and

$$V_2 = E_2 \frac{d}{2} = \frac{Qd}{2\kappa_2 \epsilon_0 A}$$

Substitute for V_1 and V_2 and simplify to obtain:

$$V = \frac{Qd}{2\kappa_1 \in_0 A} + \frac{Qd}{2\kappa_2 \in_0 A}$$
$$= \boxed{\frac{Qd}{2 \in_0 A}\left(\frac{1}{\kappa_1} + \frac{1}{\kappa_2}\right)}$$

(*c*) Use the definition of capacitance to obtain:

$$C = \frac{Q}{V} = \frac{Q}{\dfrac{Qd}{2 \in_0 A}\left(\dfrac{1}{\kappa_1} + \dfrac{1}{\kappa_2}\right)}$$
$$= \frac{2 \in_0 A}{d\left(\dfrac{\kappa_1 + \kappa_2}{\kappa_1\kappa_2}\right)} = \frac{2 \in_0 A}{d}\left(\frac{\kappa_1\kappa_2}{\kappa_1 + \kappa_2}\right)$$
$$= \boxed{2C_0\left(\frac{\kappa_1\kappa_2}{\kappa_1 + \kappa_2}\right)}$$

where $C_0 = \in_0 A/d$.

(*d*) Express the equivalent capacitance C of capacitors C_1 and C_2 in series:

$$C = \frac{C_1C_2}{C_1 + C_2}$$

Express C_1:

$$C_1 = \frac{\kappa_1 \in_0 A}{d/2} = \frac{2\kappa_1 \in_0 A}{d} = 2\kappa_1C_0$$

Express C_2:

$$C_2 = \frac{\kappa_2 \in_0 A}{d/2} = \frac{2\kappa_2 \in_0 A}{d} = 2\kappa_2C_0$$

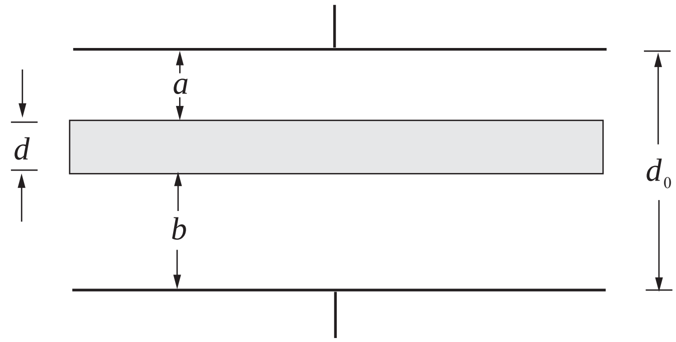
Substitute for C_1 and C_2 and simplify to obtain:

$$C = \frac{(2\kappa_1C_0)(2\kappa_2C_0)}{2\kappa_1C_0 + 2\kappa_2C_0} = \boxed{2C_0\left(\frac{\kappa_1\kappa_2}{\kappa_1 + \kappa_2}\right)},$$

a result in agreement with Part (*c*).

81 •• The plates of a parallel-plate capacitor are separated by distance d_0, and each plate has area *A*. A metal slab of thickness *d* and area *A* is inserted between the plates in such a way that the slab is parallel with the capacitor plates. (*a*) Show that the new capacitance is given by $\in_0 A/(d_0 - d)$, regardless of the distance between the metal slab and the positively charged plate. (*b*) Show that this arrangement can be modeled as a capacitor that has plate separation *a* in series with a capacitor of separation *b*, where $a + b + d = d_0$.

Picture the Problem The following diagram shows the arrangement described in the problem statement.



(*a*) and (*b*) Modeling the arrangement as a capacitor that has plate separation *a* in series with a capacitor of separation *b* gives:

$$\frac{1}{C}=\frac{a}{\epsilon_0 A}+\frac{b}{\epsilon_0 A}=\frac{a+b}{\epsilon_0 A}$$

From the diagram:

$$a+b+d=d_0 \Rightarrow a+b=d_0-d$$

Substituting for $a+b$ yields:

$$\frac{1}{C}=\frac{d_0-d}{\epsilon_0 A}\Rightarrow C=\boxed{\frac{\epsilon_0 A}{d_0-d}}$$

82 •• A parallel-plate capacitor that has plate area *A* is filled with two dielectrics of equal size, as shown in Figure 24-48. (*a*) Show that this system can be modeled as two capacitors that are connected in parallel and each have an area $\frac{1}{2}A$. (*b*) Show that the capacitance is given by $\frac{1}{2}(\kappa_1+\kappa_2)C_0$, where C_0 is the capacitance if there were no dielectric materials in the space between the plates.

Picture the Problem We can express the ratio of C_{eq} to C_0 to show that the capacitance with the dielectrics in place is $(\kappa_1+\kappa_2)/2$ times greater than that of the capacitor in the absence of the dielectrics.

(*a*) Because the capacitor plates are conductors, the potentials are the same across the entire upper and lower plates. Hence, the system is equivalent to two capacitors, each of area $\frac{1}{2}A$, in parallel.

(*b*) Relate the capacitance C_0, in the absence of the dielectrics, to the plate area and separation:

$$C_0=\frac{\epsilon_0 A}{d}$$

Express the equivalent capacitance of capacitors C_1 and C_2, each with plate area $\frac{1}{2}A$, connected in parallel, and simplify to obtain:

$$C_{\text{eq}} = C_1 + C_2$$
$$= \frac{\kappa_1 \epsilon_0 \left(\frac{1}{2}A\right)}{d} + \frac{\kappa_2 \epsilon_0 \left(\frac{1}{2}A\right)}{d}$$
$$= \frac{1}{2}\left(\frac{\epsilon_0 A}{d}\right)(\kappa_1 + \kappa_2)$$
$$= \boxed{\frac{1}{2}(\kappa_1 + \kappa_2)C_0}$$

83 •• A parallel-plate capacitor with no dielectric in the space between the plates has a plate area A and a gap width x. A charge Q is on the positively charged plate. (*a*) Find the stored electrostatic energy as a function of x. (*b*) Find the increase in energy dU due to an increase in plate separation dx from $dU = (dU/dx)\,dx$. (*c*) If F is the force exerted by one plate on the other, the work needed to move one plate a distance dx is $F\,dx = dU$. Show that $F = Q_2/(2\epsilon_0 A)$. (*d*) Show that the force in Part (*c*) equals $\frac{1}{2}EQ$, where Q is the charge on one plate and E is the electric field between the plates. Give a conceptual explanation for the factor $\frac{1}{2}$ in this result.

Picture the Problem We can use $U = Q^2/2C$ and the expression for the capacitance as a function of plate separation to express U as a function of x. Differentiation of this result with respect to x will yield dU. Because the work done in increasing the plate separation a distance dx equals the change in the electrostatic potential energy of the capacitor, we can evaluate F from dU/dx. Finally, we can express F in terms of Q and E by relating E to x using $E = V/x$ and using the definition of capacitance and the expression for the capacitance of a parallel-plate capacitor.

(*a*) Relate the electrostatic energy U stored in the capacitor to its capacitance C:

$$U = \frac{1}{2}\frac{Q^2}{C}$$

Express the capacitance as a function of the plate separation:

$$C = \frac{\epsilon_0 A}{x}$$

Substitute for C to obtain:

$$U = \boxed{\frac{Q^2}{2\epsilon_0 A}x}$$

(*b*) Use the result obtained in (*a*) to evaluate dU:

$$dU = \frac{dU}{dx}dx = \frac{d}{dx}\left[\frac{Q^2}{2\epsilon_0 A}x\right]dx$$
$$= \boxed{\frac{Q^2}{2\epsilon_0 A}dx}$$

(*c*) Relate the work needed to move one plate a distance *dx* to the change in the electrostatic potential energy of the system:

$$W = dU = Fdx$$

Solve for and evaluate *F*:

$$F = \frac{dU}{dx} = \frac{d}{dx}\left[\frac{Q^2}{2\in_0 A}x\right] = \boxed{\frac{Q^2}{2\in_0 A}}$$

(*d*) Express the electric field between the plates in terms of their separation and their potential difference:

$$E = \frac{V}{x}$$

Use the definition of capacitance to eliminate *V*:

$$E = \frac{Q}{Cx}$$

Use the expression for the capacitance of a parallel-plate capacitor to eliminate *C*:

$$E = \frac{Q}{\frac{\in_0 A}{x}x} = \frac{Q}{\in_0 A}$$

Substitute in our result from Part (*c*) to obtain:

$$F = \frac{Q(\in_0 AE)}{2\in_0 A} = \boxed{\tfrac{1}{2}QE}$$

The field *E* is due to the sum of the fields from charges $+Q$ and $-Q$ on the opposite plates of the capacitor. Each plate produces a field $\frac{1}{2}E$. and the force is the product of charge *Q* and the field $\frac{1}{2}E$.

84 •• A rectangular parallel-plate capacitor that has a length *a* and a width *b* has a dielectric that has a width *b* partially inserted a distance *x* between the plates, as shown in Figure 24-49. (*a*) Find the capacitance as a function of *x*. Neglect edge effects. (*b*) Show that your answer gives the expected results for $x = 0$ and $x = a$.

Picture the Problem We can model this capacitor as the equivalent of two capacitors connected in parallel. Let the numeral 1 denote the capacitor with the dielectric material whose constant is κ and the numeral 2 the air-filled capacitor.

(*a*) Express the equivalent capacitance of the two capacitors in parallel:

$$C(x) = C_1 + C_2 \qquad (1)$$

Use the expression for the capacitance of a parallel-plate capacitor to express C_1:

$$C_1 = \frac{\kappa \in_0 A_1}{d} = \frac{\kappa \in_0 bx}{d}$$

Express the capacitance C_0 of the capacitor with the dielectric removed; that is, $x = 0$:

$$C_0 = \frac{\in_0 ab}{d}$$

Divide C_1 by C_0 and simplify to obtain:

$$\frac{C_1}{C_0} = \frac{\frac{\kappa \in_0 bx}{d}}{\frac{\in_0 ab}{d}} = \frac{\kappa x}{a} \Rightarrow C_1 = \frac{\kappa x}{a} C_0$$

Use the expression for the capacitance of a parallel-plate capacitor to express C_2:

$$C_2 = \frac{\in_0 A_2}{d} = \frac{\in_0 b(a-x)}{d}$$

Divide C_2 by C_0 to obtain:

$$\frac{C_2}{C_0} = \frac{\frac{\in_0 b(a-x)}{d}}{\frac{\in_0 ab}{d}} = \frac{a-x}{a}$$

or, solving for C_2,

$$C_2 = \frac{a-x}{a} C_0$$

Substitute for C_1 and C_2 in equation (1) and simplify to obtain:

$$\begin{aligned} C(x) &= \frac{\kappa x}{a} C_0 + \frac{a-x}{a} C_0 \\ &= \frac{C_0}{a}\left[a + (\kappa - 1)x\right] \\ &= \boxed{\frac{\in_0 b}{d}\left[a + (\kappa - 1)x\right]} \end{aligned}$$

(*b*) Evaluate C for $x = 0$:

$$C(0) = \frac{\in_0 b}{d}[a] = \frac{\in_0 ab}{d} = \boxed{C_0}$$

as expected.

Evaluate C for $x = a$:

$$\begin{aligned} C(a) &= \frac{\in_0 b}{d}\left[a + (\kappa - 1)a\right] \\ &= \boxed{\frac{\kappa \in_0 ab}{d}} \end{aligned}$$ *as expected.*

85 ••• **[SSM]** An electrically isolated capacitor that has charge Q on its positively charged plate is partly filled with a dielectric substance as shown in Figure 24-51. The capacitor consists of two rectangular plates that have edge lengths a and b and are separated by distance d. The dielectric is inserted into the gap a distance x. (*a*) What is the energy stored in the capacitor? *Hint: the capacitor can be modeled as two capacitors connected in parallel*. (*b*) Because the energy of the capacitor decreases as x increases, the electric field must be doing work on the dielectric, meaning that there must be an electric force pulling it in. Calculate this force by examining how the stored energy varies with x. (*c*) Express the force in terms of the capacitance and potential difference V between the plates. (*d*) From where does this force originate?

Picture the Problem We can model this capacitor as the equivalent of two capacitors connected in parallel, one with an air gap and other filled with a dielectric of constant κ. Let the numeral 1 denote the capacitor with the dielectric material whose constant is κ and the numeral 2 the air-filled capacitor.

(*a*) Using the hint, express the energy stored in the capacitor as a function of the equivalent capacitance C_{eq}:

$$U = \frac{1}{2}\frac{Q^2}{C_{\text{eq}}}$$

The capacitances of the two capacitors are:

$$C_1 = \frac{\kappa \in_0 ax}{d} \text{ and } C_2 = \frac{\in_0 a(a-x)}{d}$$

Because the capacitors are in parallel, C_{eq} is the sum of C_1 and C_2:

$$\begin{aligned} C_{eq} &= C_1 + C_2 = \frac{\kappa \in_0 ax}{d} + \frac{\in_0 a(a-x)}{d} \\ &= \frac{\in_0 a}{d}(\kappa x + a - x) \\ &= \frac{\in_0 a}{d}[(\kappa - 1)x + a] \end{aligned}$$

Substitute for C_{eq} in the expression for U and simplify to obtain:

$$U = \boxed{\frac{Q^2 d}{2 \in_0 a[(\kappa-1)x + a]}}$$

(*b*) The force exerted by the electric field is given by:

$$F = -\frac{dU}{dx}$$
$$= -\frac{d}{dx}\left[\frac{1}{2}\frac{Q^2 d}{\in_0 a[(\kappa-1)x+a]}\right]$$
$$= -\frac{Q^2 d}{2\in_0 a}\frac{d}{dx}\left\{[(\kappa-1)x+a]^{-1}\right\}$$
$$= \boxed{\frac{(\kappa-1)Q^2 d}{2a\in_0 [(\kappa-1)x+a]^2}}$$

(*c*) Rewrite the result in (*b*) to obtain:

$$F = \frac{(\kappa-1)Q^2\left(\frac{a\in_0}{d}\right)}{2\left(\frac{a\in_0}{d}\right)^2[(\kappa-1)x+a]^2}$$
$$= \frac{(\kappa-1)Q^2\left(\frac{a\in_0}{d}\right)}{2C_{eq}^2}$$
$$= \boxed{\frac{(\kappa-1)a\in_0 V^2}{2d}}$$

Note that this expression is independent of *x*.

(*d*) The force originates from the fringing fields around the edges of the capacitor. The effect of the force is to pull the polarized dielectric into the space between the capacitor plates.

86 ••• A spherical capacitor consists of an solid conducting sphere that has a radius *a* and a charge +*Q* and an concentric conducting spherical shell that has an inner radius *b* and a charge of *Q*. The space between the two is filled with two different dielectric materials of dielectric constants κ_1 and κ_2. The boundary between the two dielectrics occurs a distance $\frac{1}{2}(a+b)$ from the center.
(*a*) Calculate the electric field in the regions $a < r < \frac{1}{2}(a+b)$ and $\frac{1}{2}(a+b) < r < b$. (*b*) Integrate the expression $dV = -\vec{E}\cdot d\vec{\ell}$ to obtain the potential difference, *V*, between the two conductors. (*c*) Use $C = Q/V$ to obtain an expression for the capacitance of this system. (*d*) Show that your answer from Part (*c*) simplifies to the expected one if the κ_1 equals κ_2.

Picture the Problem (*a*) Gauss's law tells us that, in the absence of dielectric materials, the electric field between the conductors is $E_0 = kQ/r^2$. In the dielectric materials, the field is reduced by the appropriate dielectric constant.

(*a*) The electric fields in the regions
$a < r < (a + b)/2$
and
$(a + b)/2 < r < b$
are given by:

$$E_1 = \boxed{\frac{kQ}{\kappa_1 r^2}} \text{ and } E_2 = \boxed{\frac{kQ}{\kappa_2 r^2}}$$

(*b*) Because the electric field is directed radially away from the center, the potential of the outer spherical shell is less than the potential of the inner sphere. Hence the difference in potential between the spheres is given by:

$$\begin{aligned}|V| &= |V_1 - V_2| \\ &= \left| -\int_a^{\frac{1}{2}(a+b)} E_1 dr - \left(-\int_{\frac{1}{2}(a+b)}^{b} E_2 dr \right) \right| \\ &= \left| -\frac{kQ}{\kappa_1} \int_a^{\frac{1}{2}(a+b)} r^{-2} dr + \frac{kQ}{\kappa_2} \int_{\frac{1}{2}(a+b)}^{b} r^{-2} dr \right|\end{aligned}$$

Evaluating the integrals and simplifying yields:

$$\begin{aligned}|V| &= \left| \frac{kQ}{\kappa_1}\frac{1}{r}\bigg]_a^{\frac{1}{2}(a+b)} + \frac{kQ}{\kappa_2}\frac{1}{r}\bigg]_{\frac{1}{2}(a+b)}^{b} \right| = \left| \frac{kQ}{\kappa_1}\left(\frac{2}{a+b} - \frac{1}{a}\right) + \frac{kQ}{\kappa_2}\left(\frac{1}{b} - \frac{2}{a+b}\right) \right| \\ &= \left| \frac{kQ(a-b)}{a+b}\frac{\kappa_1 a + \kappa_2 b}{\kappa_1\kappa_2 ab} \right| = \boxed{\frac{kQ(b-a)}{a+b}\frac{\kappa_1 a + \kappa_2 b}{\kappa_1\kappa_2 ab}}\end{aligned}$$

(*c*) Use the definition of capacitance and simplify to obtain:

$$\begin{aligned}C &= \frac{Q}{|V|} = \frac{Q}{\dfrac{kQ(a-b)}{a+b}\dfrac{\kappa_1 a + \kappa_2 b}{\kappa_1\kappa_2 ab}} \\ &= \boxed{\frac{\kappa_1\kappa_2 ab(a+b)}{k(b-a)(\kappa_1 a + \kappa_2 b)}}\end{aligned}$$

(*d*) Letting $\kappa_1 = \kappa_2 = \kappa$, the result in Part (*c*) reduces to the expression for a spherical capacitor filled with just one dielectric material. In particular, if the capacitor is air filled ($\kappa = 1.00$), the expression for *C* is that for an air-filled spherical capacitor.

$$\begin{aligned}C &= \frac{\kappa\kappa ab(a+b)}{k(b-a)(\kappa a + \kappa b)} \\ &= \frac{\kappa ab}{k(b-a)} \\ &= \boxed{\frac{4\pi \epsilon_0 \kappa ab}{b-a}}\end{aligned}$$

87 ••• A capacitance balance is shown in Figure 24-50. The balance has a weight attached to one side and a capacitor that has a variable gap width on the other side. Assume the upper plate of the capacitor has negligible mass. When the capacitor potential difference between the plates is V_0, the attractive force between

the plates balances the weight of the hanging mass. (*a*) Is the balance stable? That is, if we balance it out, and then move the plates a little closer together, will they snap shut or move back to the equilibrium point? (*b*) Calculate the value of V_0 required to balance an object of mass M, assuming the plates are separated by distance d_0 and have area A. *HINT: A useful relation is that the force between the plates is equal to the derivative of the stored electrostatic energy with respect to the plate separation.*

Picture the Problem To avoid have to write dd (as in $F = -dE/dd$) in relating the force on the electrostatic balance plates to the electric field in the region between them, let ℓ be the variable separation of the plates. We can use the definition of the work done in charging the capacitor to relate the force on the upper plate to the energy stored in the capacitor. Solving this expression for the force and substituting for the energy stored in a parallel-plate capacitor will yield an expression that we can use to decide whether the balance is stable. We can use this same expression and a condition for equilibrium to find the voltage required to balance the object whose mass is M.

(*a*) Express the work done in charging the capacitor (the energy stored in it) in terms of the force between the plates:

$$dW = dE = -Fd\ell \Rightarrow F = -\frac{dE}{d\ell}$$

The energy stored in the capacitor is given by:

$$E = \frac{1}{2}CV_0^2 = \frac{1}{2}\left(\frac{\epsilon_0 A}{\ell}\right)V_0^2$$

Differentiate E with respect to ℓ to obtain:

$$F = -\frac{d}{d\ell}\left[\frac{1}{2}\left(\frac{\epsilon_0 A}{\ell}\right)V_0^2\right] = \left(\frac{\epsilon_0 A}{2\ell^2}\right)V_0^2$$

or, changing back to the variable d,

$$F = \left(\frac{\epsilon_0 A}{2d^2}\right)V_0^2$$

Because F increases as ℓ decreases, a decrease in plate separation will unbalance the system. Hence, the balance is unstable.

(*b*) Apply $\sum F = 0$ to the object whose mass is M when the plate separation is d_0 to obtain:

$$Mg - \left(\frac{\epsilon_0 A}{2d_0^2}\right)V^2 = 0 \Rightarrow V = \boxed{d_0\sqrt{\frac{2Mg}{\epsilon_0 A}}}$$

88 ••• You are an intern at an engineering company that makes capacitors used for energy storage in pulsed lasers. Your manger asks your team to construct a parallel-plate, air-gap capacitor that will store 100 kJ of energy. (*a*) What

minimum volume is required between the plates of the capacitor? (*b*) Suppose you have developed a dielectric that has a dielectric strength of 3.00×10^8 V/m and a dielectric constant of 5.00. What volume of this dielectric, between the plates of the capacitor, is required for it to be able to store 100 kJ of energy?

Picture the Problem Recall that the dielectric strength of air is 3.00 MV/m. We can express the maximum energy to be stored in terms of the capacitance of the air-gap capacitor and the maximum potential difference between its plates. This maximum potential can, in turn, be expressed in terms of the maximum electric field (dielectric strength) possible in the air gap. We can solve the resulting equation for the volume of the space between the plates. In Part (*b*) we can modify the equation we derive in Part (*a*) to accommodate a dielectric with a constant other than 1.

(*a*) Express the energy stored in the capacitor in terms of its capacitance and the potential difference across it:

$$U = \tfrac{1}{2}CV^2$$

Express the capacitance of the air-gap parallel-plate capacitor:

$$C = \frac{\epsilon_0 A}{d}$$

Relate the potential difference across the plates to the electric field between them:

$$V = Ed$$

Substitute for C and V in the expression for U to obtain:

$$U = \tfrac{1}{2}\left(\frac{\epsilon_0 A}{d}\right)(Ed)^2$$

$$= \tfrac{1}{2}\epsilon_0 (Ad)E^2 = \tfrac{1}{2}\epsilon_0 \upsilon E^2$$

where $\upsilon = Ad$ is the volume between the plates.

Solving for $\upsilon = \upsilon_{max}$ yields:

$$\upsilon_{max} = \frac{2U_{max}}{\epsilon_0 E_{max}^2} \qquad (1)$$

Substitute numerical values and evaluate υ_{max}:

$$\upsilon_{max} = \frac{2(100\,\mathrm{kJ})}{(8.85\times10^{-12}\ \mathrm{C^2/N\cdot m^2})(3\,\mathrm{MV/m})^2}$$

$$= \boxed{2.51\times10^3\ \mathrm{m^3}}$$

(*b*) With the dielectric in place equation (1) becomes:

$$\upsilon_{max} = \frac{2U_{max}}{\kappa \in_0 E_{max}^2} \quad (2)$$

Evaluate equation (2) with $\kappa = 5.00$ and $E_{max} = 3.00 \times 10^8$ V/m:

$$\upsilon_{max} = \frac{2(100\,\text{kJ})}{(5.00)\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(3.00\times10^8\,\frac{\text{V}}{\text{m}}\right)^2} = \boxed{5.02\times10^{-2}\ \text{m}^3}$$

89 ••• Consider two parallel-plate capacitors, C_1 and C_2, that are connected in parallel. The capacitors are identical except that C_2 has a dielectric inserted between its plates. A 200 V battery is connected across the combination until electrostatic equilibrium is established, and then the battery is disconnected. (*a*) What is the charge on each capacitor? (*b*) What is the total stored energy of the capacitors? (*c*) The dielectric is removed from C_2. What is the final stored energy of the capacitors? (*d*) What is the final voltage across the two capacitors?

Picture the Problem We can use the definition of capacitance to find the charge on each capacitor in Part (*a*). In Part (*b*) we can express the total energy stored as the sum of the energy stored on the two capacitors by using our result from (*a*) for the charge on each capacitor. When the dielectric is removed in Part (*c*) each capacitor will carry half the charge carried by the capacitor system previously and we can proceed as in (*b*). Knowing the total charge stored by the capacitors, we can use the definition of capacitance to find the final voltage across the two capacitors in Part (*d*).

(*a*) Use the definition of capacitance to express the charge on each capacitor as a function of its capacitance:

$$Q_1 = C_! V = \boxed{(200\,\text{V})C_1}$$

and

$$Q_2 = C_2 V = \kappa C_1 V = \boxed{(200\,\text{V})\kappa C_1}$$

(*b*) Express the total stored energy of the capacitors as the sum of stored energy in each capacitor:

$$\begin{aligned} U &= U_1 + U_2 = \tfrac{1}{2}C_1V^2 + \tfrac{1}{2}C_2V^2 \\ &= \tfrac{1}{2}C_1V^2 + \tfrac{1}{2}\kappa C_1V^2 \\ &= \tfrac{1}{2}C_1V^2(1+\kappa) \\ &= \tfrac{1}{2}(200\,\text{V})^2 C_1(1+\kappa) \\ &= \boxed{(2.00\times10^4\,\text{V}^2)(1+\kappa)C_1} \end{aligned}$$

(*c*) With the dielectric removed, each capacitor carries charge $Q/2$. Express the final energy stored by the capacitors under this condition:

$$U_f = \frac{1}{2}\frac{Q_1^2}{C_1} + \frac{1}{2}\frac{Q_2^2}{C_2} = \frac{1}{2}\frac{Q^2}{4C_1} + \frac{1}{2}\frac{Q^2}{4C_1}$$
$$= \frac{Q^2}{4C_1}$$

Using the definition of capacitance, express the total charge carried by the capacitors with the dielectric in place in C_2:

$$Q = Q_1 + Q_2 = C_1V + C_2V$$
$$= C_1V + \kappa C_1V = C_1V(1+\kappa)$$
$$= (200\text{ V})C_1(1+\kappa)$$

Substitute for Q in the expression for U_f to obtain:

$$U_f = \frac{[(200\text{ V})C_1(1+\kappa)]^2}{4C_1}$$
$$= \boxed{(1.00\times10^4\text{ V}^2)C_1(1+\kappa)^2}$$

(*d*) Use the definition of capacitance to express the final voltage across the capacitors:

$$V_f = \frac{Q}{C_{eq}} = \frac{(200\text{ V})C_1(1+\kappa)}{2C_1}$$
$$= \boxed{100(1+\kappa)\text{V}}$$

90 ••• A capacitor is constructed of two coaxial conducting thin cylindrical shells of radii a and b ($b > a$), which have a length $L >> b$. A charge of $+Q$ is on the inner cylinder, and a charge of $-Q$ is on the outer cylinder. The region between the two cylinders is filled with a material that has a dielectric constant κ. (*a*) Find the potential difference between the cylinders. (*b*) Find the density of the free charge σ_f on the inner cylinder and the outer cylinder. (*c*) Find the bound charge density σ_b on the inner cylindrical surface of the dielectric and on the outer cylindrical surface of the dielectric. (*d*) Find the total stored energy. (*e*) If the dielectric will move without friction, how much mechanical work is required to remove the dielectric cylindrical shell?

Picture the Problem We can use the definition of capacitance and the expression for the capacitance of a cylindrical capacitor to find the potential difference between the cylinders. In Part (*b*) we can apply the definition of surface charge density to find the density of the free charge σ_f on the inner and outer cylindrical surfaces. We can use the fact that that Q and Q_b are proportional to E and E_b to express Q_b at a and b and then apply the definition of surface charge density to express $\sigma_b(a)$ and $\sigma_b(b)$. In Part (*d*) we can use $U = \frac{1}{2}QV$ to find the total stored electrostatic energy and in (*e*) find the mechanical work required from the change in energy of the system resulting from the removal of the dielectric cylindrical shell.

(*a*) Using the definition of capacitance, relate the potential difference between the cylinders to their charge and capacitance:

$$V = \frac{Q}{C}$$

Express the capacitance of a cylindrical capacitor as a function of its radii *a* and *b* and length *L*:

$$C = \frac{2\pi \in_0 \kappa L}{\ln(b/a)}$$

Substituting for *C* and simplifying yields:

$$V = \frac{Q\ln(b/a)}{2\pi \in_0 \kappa L} = \boxed{\frac{2kQ\ln(b/a)}{\kappa L}}$$

(*b*) Apply the definition of surface charge density to obtain:

$$\sigma_f(a) = \boxed{\frac{Q}{2\pi aL}}$$

and

$$\sigma_f(b) = \boxed{\frac{-Q}{2\pi bL}}$$

(*c*) Noting that Q and Q_b are proportional to E and E_b, express Q_b at *a* and *b*:

$$Q_b(a) = \frac{-Q(\kappa-1)}{\kappa}$$

and

$$Q_b(b) = \frac{Q(\kappa-1)}{\kappa}$$

Apply the definition of surface charge density to express $\sigma_b(a)$ and $\sigma_b(b)$:

$$\sigma_b(a) = \frac{Q_b(a)}{A} = \frac{\frac{-Q(\kappa-1)}{\kappa}}{2\pi aL} = \boxed{\frac{-Q(\kappa-1)}{2\pi aL\kappa}}$$

and

$$\sigma_b(b) = \frac{Q_b(b)}{A} = \frac{\frac{Q(\kappa-1)}{\kappa}}{2\pi bL} = \boxed{\frac{Q(\kappa-1)}{2\pi bL\kappa}}$$

(*d*) Express the total stored energy in terms of the charge stored and the potential difference between the cylinders:

$$U = \tfrac{1}{2}QV = \tfrac{1}{2}Q\left[\frac{2kQ\ln(b/a)}{\kappa L}\right] = \boxed{\frac{kQ^2\ln(b/a)}{\kappa L}}$$

(*e*) Express the work required to remove the dielectric cylindrical shell in terms of the change in the potential energy of the system:

$$W = \Delta U = U' - U$$

where $U' = \kappa U$ is the potential energy of the system with the dielectric shell in place.

Substitute for U and U' and simplify to obtain:

$$W = \kappa U - U = U(\kappa - 1)$$
$$= \boxed{\frac{kQ^2(\kappa - 1)\ln(b/a)}{\kappa L}}$$

91 ••• Before Switch S is closed, as shown in Figure 24-51 the voltage across the terminals of the switch is 120 V and the voltage across the capacitor labeled C_1 is 40.0 V. The capacitance of C_1 is 0.200 μF. The total energy stored in the two capacitors is 1.44 mJ. After closing the switch, the voltage across each capacitor is 80.0 V, and the energy stored by the two capacitors has dropped to 960 μJ. Determine the capacitance of C_2 and the charge on that capacitor before the switch was closed.

Picture the Problem Note that, with switch S closed, C_1 and C_2 are in parallel and we can use $U_{\text{closed}} = \frac{1}{2}C_{\text{eq}}V^2$ and $C_{\text{eq}} = C_1 + C_2$ to obtain an equation we can solve for C_2. We can use the definition of capacitance to express Q_2 in terms of V_2 and C_2 and $U_{\text{open}} = \frac{1}{2}C_1V_1^2 + \frac{1}{2}C_2V_2^2$ to obtain an equation from which we can determine V_2.

Express the energy stored in the capacitors after the switch is closed:

$$U_{\text{closed}} = \tfrac{1}{2}C_{\text{eq}}V^2$$

Express the equivalent capacitance of C_1 and C_2 in parallel:

$$C_{\text{eq}} = C_1 + C_2$$

Substitute for C_{eq} to obtain:

$$U_{\text{closed}} = \tfrac{1}{2}(C_1 + C_2)V^2$$

Solving for C_2 yields:

$$C_2 = \frac{2U_{\text{closed}}}{V^2} - C_1$$

Substitute numerical values and evaluate C_2:

$$C_2 = \frac{2(960\ \mu\text{J})}{(80\ \text{V})^2} - 0.200\ \mu\text{F} = \boxed{0.100\ \mu\text{F}}$$

Express the charge on C_2 when the switch is open:

$$Q_2 = C_2V_2 \qquad (1)$$

Express the energy stored in the capacitors with the switch open:

$$U_{\text{open}} = \tfrac{1}{2}C_1V_1^2 + \tfrac{1}{2}C_2V_2^2$$

Solving for V_2 yields:

$$V_2 = \sqrt{\frac{2U_{\text{open}} - C_1V_1^2}{C_2}}$$

Substitute for V_2 in equation (1) to obtain:

$$Q_2 = C_2\sqrt{\frac{2U_{\text{open}} - C_1V_1^2}{C_2}} = \sqrt{C_2\left(2U_{\text{open}} - C_1V_1^2\right)}$$

Substitute numerical values and evaluate Q_2:

$$Q_2 = \sqrt{(0.100\,\mu\text{F})\left[2(1.44\,\text{mJ}) - (0.200\,\mu\text{F})(40.0\,\text{V})^2\right]} = \boxed{16.0\,\mu\text{C}}$$

92 ••• An air-filled parallel-plate capacitor that has gap-width d has plates which each have an area A. The capacitor is charged to a potential difference V and is then removed from the voltage source. A dielectric slab that has a dielectric constant of 2.00, a thickness d, and an area $\frac{1}{2}A$ is then inserted, as shown in Figure24-52. Let σ_1 be the free charge density at the conductor–dielectric surface, and let σ_2 be the free charge density at the conductor–air surface. (*a*) Explain why the electric field must have the same value inside the dielectric as in the free space between the plates. (*b*) Show that $\sigma_1 = 2\sigma_2$. (*c*) Show that the final capacitance (after the slab is inserted) is 1.50 times the capacitance when the capacitor is filled with air. (*d*) Show that the final potential difference is $\frac{2}{3}V$. (*e*) Show that energy stored after the slab is inserted is only two-thirds of the energy stored before insertion.

Picture the Problem (*b*) We can express the electric fields in the dielectric and in the free space in terms of the charge densities and then use the fact that the electric field has the same value inside the dielectric as in the free space between the plates to establish that $\sigma_1 = 2\sigma_2$. In Parts (*c*) and (*d*) we can model the system as two capacitors in parallel to show that the equivalent capacitance is $3\epsilon_0A/(2d)$ and then use the definition of capacitance to show that the new potential difference is $\frac{2}{3}V$.

(*a*) The potential difference between the plates is the same for both halves (the plates are equipotential surfaces). Therefore, $E = V/d$ must be the same everywhere between the plates.

(*b*) Relate the electric field in each region to σ and κ:

$$E = \frac{\sigma}{\kappa \in_0} \Rightarrow \sigma = \kappa \in_0 E$$

Express σ_1 and σ_2:

$$\sigma_1 = \kappa_1 \in_0 E_1 = 2 \in_0 E_1$$

and

$$\sigma_2 = \kappa_2 \in_0 E_2 = \in_0 E_1$$

Divide the 1st of these equations by the 2nd and simplify to obtain:

$$\boxed{\sigma_1 = 2\sigma_2}$$

(*c*) Model the partially dielectric-filled capacitor as two capacitors in parallel to obtain:

$$C_{eq} = C_1 + C_2$$

where

$$C_1 = \frac{\kappa \in_0 \left(\frac{1}{2}A\right)}{d} = \frac{\kappa \in_0 A}{2d}$$

and

$$C_2 = \frac{\in_0 \left(\frac{1}{2}A\right)}{d} = \frac{\in_0 A}{2d}$$

Substitute for C_1 and C_2 and simplify to obtain:

$$C_{eq} = \frac{\kappa \in_0 A}{2d} + \frac{\in_0 A}{2d} = \frac{2 \in_0 A}{2d} + \frac{\in_0 A}{2d}$$

$$= \frac{3 \in_0 A}{2d} = \boxed{1.50 C_{\text{air-filled}}}$$

(*d*) Use the definition of capacitance to relate V_f, Q_f, and C_f:

$$V_f = \frac{Q_f}{C_f}$$

Because the capacitors are in parallel:

$$Q_f = Q_i = VC_i = \frac{V \in_0 A}{d}$$

Substitute for Q_f and C_f and simplify to obtain:

$$V_f = \frac{V \in_0 A}{C_f d} = \frac{V \in_0 A}{\left(\frac{3 \in_0 A}{2d}\right)d} = \boxed{\tfrac{2}{3}V}$$

(*e*) The energy stored after the slab is inserted is given by:

$$U_f = \tfrac{1}{2} C_f V_f^2$$

Substituting for C_f and V_f and simplifying yields:

$$U_f = \tfrac{1}{2}\left(\tfrac{3}{2}C_i\right)\left(\tfrac{2}{3}V\right)^2 = \tfrac{1}{3}C_i V^2 = \boxed{\tfrac{2}{3}U_i}$$

The presence of the dielectric slab reduces the potential difference between the capacitor plates and, hence, the energy stored in the capacitor.

93 ••• A capacitor has rectangular plates of length a and width b. The top plate is inclined at a small angle, as shown in Figure 24-53. The plate separation varies from y_0 at the left to $2y_0$ at the right, where y_0 is much less than a or b. Calculate the capacitance of this arrangement. *HINT*: *Break the problem up into a parallel combination. Choose strips of width dx and length b to approximate small (differential) capacitors (each having a value of dC). Each will have a plate area of bdx and separation distance $y_0 + (y_0/a)x$. Then argue that these differential capacitors are connected in parallel.*

Picture the Problem Choose a coordinate system in which the +x direction is the right and the origin is at the left edge of the capacitor. We can express an element of capacitance dC and then integrate this expression to find C for this capacitor.

Express an element of capacitance dC of length b, width dx and separation $d = y_0 + (y_0/a)x$:

$$dC = \frac{\epsilon_0\, b}{d}dx = \frac{\epsilon_0\, b}{y_0(1+x/a)}dx$$

These elements are all in parallel, so the total capacitance is obtained by integration:

$$C = \frac{\epsilon_0\, b}{y_0}\int_0^{y_0}\frac{1}{1+x/a}dx = \boxed{\frac{\epsilon_0\, ab}{y_0}\ln(2)}$$

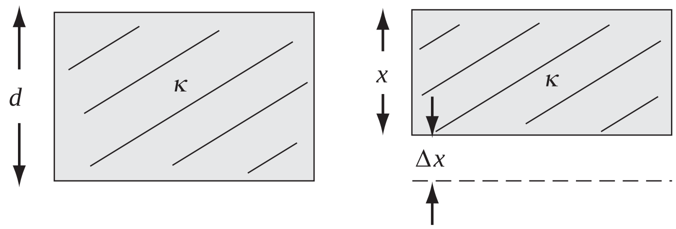
94 ••• Not all dielectrics that separate the plates of a capacitor are rigid. For example, the membrane of a nerve axon is a bi-lipid layer that has a finite compressibility. Consider a parallel-plate capacitor whose plate separation is maintained by a material that has a dielectric constant of 3.00, a dielectric strength of 40.0 kV/mm and a Young's modulus[1] for compressive stress of 5.00×10^6 N/m^2. When the potential difference between the capacitor plates is zero, the thickness of the dielectric is equal to 0.200 mm and the capacitance of the capacitor is given by C_0. (*a*) Derive an expression for the capacitance, as a function of the potential difference between the capacitor plates. (*b*) What is the maximum value of this potential difference? (Assume that the dielectric constant and the dielectric strength do *not* change under compression.)

Picture the Problem The diagram below and to the left shows the dielectric-filled parallel-plate capacitor before compression and the diagram to the right shows the capacitor when the plate separation has been reduced to x. We can use the definition of capacitance and the expression for the capacitance of a parallel-plate capacitor to derive an expression for the capacitance as a function of voltage across the capacitor. We can find the maximum voltage that can be applied from the dielectric strength of the dielectric and the separation of the plates. In Part (*c*) we can find the fraction of the total energy that is electrostatic field energy and

---

[1] Young's modulus is discussed in Section 12-8.

the fraction that is mechanical stress energy by expressing either of these as a fraction of their sum.



(*a*) Use its definition to express the capacitance as a function of the voltage across the capacitor:

$$C(V)=\frac{Q}{V} \qquad (1)$$

The limiting value of the capacitance is:

$$C_0=\frac{\kappa \in_0 A}{d}$$

Substitute numerical values and evaluate C_0:

$$C_0=\frac{3\left(8.854\times10^{-12}\,\frac{\mathrm{C}^2}{\mathrm{N\cdot m^2}}\right)A}{0.200\,\mathrm{mm}}$$

$$=0.133\times10^{-6}\,A\frac{\mathrm{C}^2}{\mathrm{N\cdot m^3}}$$

Let x be the variable separation. Because κ is independent of x:

$$C(x)=\frac{\kappa \in_0 A}{x}$$

and

$$Q(x)=C(x)V=\frac{\kappa \in_0 A}{x}V$$

Substitute in equation (1) to obtain:

$$C(V)=\frac{\frac{\kappa \in_0 A}{x}V}{V}=\frac{\kappa \in_0 A}{x} \qquad (2)$$

$$=\frac{\kappa \in_0 A}{d-\Delta x}$$

The force of attraction between the plates is given in Problem 95 (*c*):

$$F=\frac{Q^2(x)}{2\kappa \in_0 A}$$

Substitute to obtain:

$$F=\frac{\left(\frac{\kappa\in_0 A}{x}V\right)^2}{2\kappa\in_0 A}=-\frac{\kappa\in_0 AV^2}{2x^2}$$

where the minus sign is used to indicate that the force acts to decrease the plate separation *x*.

Apply Hooke's law to relate the stress to the strain:

$$Y=\frac{F/A}{\Delta x/x}\text{ or }\frac{\Delta x}{x}=\frac{F}{YA}$$

Substitute for *F* to obtain:

$$\frac{\Delta x}{x}=-\frac{\kappa\in_0 V^2}{2Yx^2}$$

and

$$\Delta x=-\frac{\kappa\in_0 V^2}{2Yx}=-\frac{\kappa\in_0 V^2}{2Yd}\qquad(3)$$

provided $\Delta x \ll d$

The voltage across the capacitor is:

$$V=E_{max}d=(40.0\,\text{kV/mm})(0.200\,\text{mm})=8.00\,\text{kV}$$

Substitute numerical values in equation (3) and evaluate Δx:

$$\Delta\boldsymbol{x}=-\frac{3\left(8.854\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)(8.00\,\text{kV})^2}{2\left(5.00\times10^6\,\text{N/m}^2\right)(0.200\,\text{mm})}=8.50\times10^{-7}\,\text{m}=8.50\times10^{-4}\,\text{mm}$$

Substitute in equation (2) to obtain:

$$C(V)=\frac{\kappa\in_0 A}{d-\frac{\kappa\in_0 V^2}{2Yd}}=\frac{\kappa\in_0 A}{d\left(1-\frac{\kappa\in_0 V^2}{2Yd^2}\right)}=C_0\left(1-\frac{\kappa\in_0 V^2}{2Yd^2}\right)^{-1}\approx\boxed{C_0\left(1+\frac{\kappa\in_0 V^2}{2Yd^2}\right)}$$

provided $\Delta x \ll d$.

(*b*) Express the maximum voltage that can be applied in terms of the maximum electric field:

$$V_{max}=E_{max}(d-\Delta x)=(40.0\,\text{kV/mm})\left(0.200\,\text{mm}-8.50\times10^{-4}\,\text{mm}\right)=\boxed{7.97\,\text{kV}}$$

Chapter 25
Electric Current and Direct-Current Circuits

Conceptual Problems

1 • In our study of electrostatics, we concluded that no electric field exists within the material of a conductor in electrostatic equilibrium. Why can we discuss electric fields within the material of conductors in this chapter?

Determine the Concept In earlier chapters the conductors are constrained to be in electrostatic equilibrium. In this chapter this constraint is no longer in place.

2 • Figure 25-12 shows a mechanical analog of a simple electric circuit. Devise another mechanical analog in which the current is represented by a flow of water instead of marbles. In the water circuit, what would be analogous to the battery? What would be analogous to the wire? What would be analogous to the resistor?

Determine the Concept The analog is a wind-up water pump that pumps water through a tube with a necked down section. One end of the tube is connected to the output port of the pump, and the other end of the tube is connected to the input port of the pump. The pump, including the spring, is analogous to the battery. The tube is analogous to the wires. The necked down section is analogous to the resistor.

3 • Wires A and B are both made of copper. The wires are connected in series, so we know they carry the same current. However, the diameter of wire A is twice the diameter of wire B. Which wire has the higher number density (number per unit volume) of charge carriers? (*a*) A, (*b*) B, (*c*) They have the same number density of charge carriers.

Determine the Concept Equation 25-3 ($I = qnAv_d$) relates the current I in a wire to the charge q of the charge carriers, the number density n of charge carriers, the cross-sectional area A of the wire, and the drift speed v_d of the charge carriers. Both the number density of the charge carriers and the resistivity are properties of the substance, and do not depend on the current. Because the number density of carriers may, like resistivity, vary slowly with temperature and the drift speeds are not equal in the two wires, the correct answer is $\boxed{(c)}$.

4 • The diameters of copper wires A and B are equal. The current carried by wire A is twice the current carried by wire B. In which wire do the charge carriers have the higher drift speed? (*a*) A (*b*) B (*c*) They have the same drift speed.

Determine the Concept Equation 25-3 ($I = qnAv_d$) relates the current I in a wire to the charge q of the charge carriers, the number density n of charge carriers, the cross-sectional area A of the wire, and the drift velocity v_d of the charge carriers. Both the number density of the charge carriers and the resistivity are properties of the substance, and do not depend on the current. Because the cross-sectional areas, the charge of the charge carriers, and the number densities of the charge carriers are the same for the two wires, the drift speed of the charge carriers will be higher in the wire carrying the larger current. Because wire A carries the larger current, $\boxed{(a)}$ is correct.

5 • Wire A and wire B are identical copper wires. The current carried by wire A is twice the current carried by wire B. Which wire has the higher current density? (*a*) A, (*b*) B, (*c*) They have the same current density. (*d*) None of the above

Determine the Concept The current density is the ratio of the current to the cross-sectional area of the conductor. Because the wires are identical, their cross-sectional areas are the same and their current densities are directly proportional to their currents. Because wire A carries the larger current, $\boxed{(a)}$ is correct.

6 • Consider a metal wire that has each end connected to a different terminal of the same battery. Your friend argues that no matter how long the wire is, the drift speed of the charge carriers in the wire is the same. Evaluate your friend's claim.

Determine the Concept The longer the wire is, the higher its resistance is. Thus, the longer the wire is the smaller the current in the wire is. The smaller the current is, the smaller the drift speed of the charge carriers is. The claim that the drift speed is independent of length is not true.

7 • In a resistor, the direction of the current must always be in the ″downhill″ direction, that is, in the direction of decreasing electric potential. Is it also the case that in a battery, the direction of the current must always be ″downhill″? Explain your answer.

Determine the Concept No, it is not necessarily true for a battery. Under normal operating conditions, the current in the battery is in the direction away from the negative battery terminal and toward the positive battery terminal. That is, it is opposite to the direction of the electric field.

8 • Discuss the distinction between an emf and a potential difference.

Determine the Concept An emf is a source of energy that gives rise to a potential difference between two points and may result in current flow if there is a conducting path whereas a potential difference is the consequence of two points in space being at different potentials.

9 • Wire A and wire B are made of the same material and have the same length. The diameter of wire A is twice the diameter of wire B. If the resistance of wire B is R, then what is the resistance of wire A? (Neglect any effects that temperature may have on resistance.) (*a*) R, (*b*) $2R$, (*c*) $R/2$, (*d*) $4R$, (*e*) $R/4$,

Picture the Problem The resistances of the wires are given by $R = \rho L/A$, where L is the length of the wire and A is its cross-sectional area. Because the resistance of a wire varies inversely with its cross-sectional area and its cross-sectional area varies with the square of its diameter, the wire that has the larger diameter will have a resistance that is one fourth the resistance of the wire that has the smaller diameter. Because wire A has a diameter that is twice that of wire B, its resistance is one-fourth the resistance of wire B. $\boxed{(e)}$ is correct.

10 • Two cylindrical copper wires have the same mass. Wire A is twice as long as wire B. (Neglect any effects that temperature may have on resistance.) Their resistances are related by (*a*) $R_A = 8R_B$, (*b*) $R_A = 4R_B$, (*c*) $R_A = 2R_B$, (*d*) $R_A = R_B$.

Determine the Concept The resistance of a wire is given by $R = \rho L/A$, where L is the length of the wire and A is its cross-sectional area. Because the wires have the same masses, their volumes must be the same. Because their volumes are the same, the cross-sectional area of wire A must be half the cross-sectional area of wire B. So wire A must have a resistance, based solely on its cross-sectional area, that is twice the resistance of wire B. Because it is also twice as long as wire B, its resistance will be four times the resistance of wire B. $\boxed{(b)}$ is correct.

11 • If the current in a resistor is I, the power delivered to the resistor is P. If the current in the resistor is increased to $3I$, what is the power then delivered to the resistor? (Assume the resistance of the resistor does not change.) (*a*) P, (*b*) $3P$, (*c*) $P/3$, (*d*) $9P$, (*e*) $P/9$

Picture the Problem The power dissipated in the resistor is given by $P = I^2R$. Because of this quadratic dependence of the power dissipated on the current, tripling the current in the resistor increases its resistance by a factor of 9. $\boxed{(d)}$ is correct.

12 • If the potential drop across the resistor is V, the power delivered to the resistor is P. If the potential drop is increased to $2V$, what is the power delivered to the resistor then equal to? (*a*) P, (*b*) $2P$, (*c*) $4P$, (*d*) $P/2$, (*e*) $P/4$

Picture the Problem Assuming the current (which depends on the resistance) to be constant, the power dissipated in a resistor is directly proportional to the square of the potential drop across it. Hence, doubling the potential drop across a resistor increases the power delivered to the resistor by a factor of 4. $\boxed{(c)}$ is correct.

13 • **[SSM]** A heater consists of a variable resistor (a resistor whose resistance can be varied) connected across an ideal voltage supply. (An ideal voltage supply is one that has a constant emf and a negligible internal resistance.) To increase the heat output, should you decrease the resistance or increase the resistance? Explain your answer.

Determine the Concept You should decrease the resistance. The heat output is given by $P = V^2/R$. Because the voltage across the resistor is constant, decreasing the resistance will increase P.

14 • One resistor has a resistance R_1 and another resistor has a resistance R_2. The resistors are connected in parallel. If $R_1 >> R_2$, the equivalent resistance of the combination is approximately (*a*) R_1, (*b*) R_2, (*c*) 0, (*d*) infinity.

Determine the Concept The equivalent resistance of the two resistors connected in parallel is given by $\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2}$. If $R_1 >> R_2$, then the reciprocal of R_1 is very small and $\frac{1}{R_{eq}} \approx \frac{1}{R_2}$. Hence $R_{eq} \approx R_2$ and $\boxed{(b)}$ is correct.

15 • One resistor has a resistance R_1 and another resistor has a resistance R_2. The resistors are connected in series. If $R_1 >> R_2$, the equivalent resistance of the combination is approximately (*a*) R_1, (*b*) R_2, (*c*) 0, (*d*) infinity.

Determine the Concept The equivalent resistance of the two resistors connected in series is given by $R_{eq} = R_1 + R_2 = R_1\left(1 + \frac{R_2}{R_1}\right)$. If $R_1 >> R_2$, then R_2/R_1 is very small and $R_{eq} \approx R_1$. Hence $\boxed{(a)}$ is correct.

16 • A parallel combination consisting of resistors A and B is connected across the terminals of a battery. The resistor A has twice the resistance of resistor B. If the current carried by resistor A is I, then what is the current carried by resistor B? (*a*) I, (*b*) $2I$, (*c*) $I/2$, (*d*) $4I$, (*e*) $I/4$

Picture the Problem Ohm's law states that the current in a resistor is proportional to the potential drop across the resistor. Because the potential difference across resistors A and connected in parallel is the same for each resistor, the resistor with half the resistance of the other resistor will carry twice the current carried by the resistor with the larger resistance. Because resistor A has twice the resistance of resistor B, resistor B will carry twice the current of resistor A. $\boxed{(b)}$ is correct.

17 • A series combination consisting of resistors *A* and *B* is connected across the terminals of a battery. The resistor A has twice the resistance of resistor B. If the current carried by resistor A is *I*, then what is the current carried by resistor B? (*a*) *I,* (*b*) 2*I*, (*c*) *I*/2, (*d*) 4*I*, (*e*) *I*/4

Determine the Concept In a series circuit, because there are no alternative pathways, all resistors carry the same current. $\boxed{(a)}$ is correct.

18 • Kirchhoff's junction rule is considered to be a consequence of (*a*) conservation of charge, (*b*) conservation of energy, (*c*) Newton's laws, (*d*) Coulomb's law, (*e*) quantization of charge.

Determine the Concept While Kirchhoff's junction rule is a statement about current, recall that current is the rate at which charge passes some point in space. Hence, the junction rule is actually a statement that charge is conserved. $\boxed{(a)}$ is correct.

19 • True or False:

(*a*) An ideal voltmeter has a zero internal resistance.
(*b*) An ideal ammeter has a zero internal resistance.
(*c*) An ideal voltage source has a zero internal resistance

(*a*) False. An ideal voltmeter would have infinite resistance. A voltmeter consists of a galvanometer movement connected in series with a large resistance. The large resistor accomplishes two purposes; 1) it protects the galvanometer movement by limiting the current drawn by it, and 2) minimizes the loading of the circuit by the voltmeter by placing a large resistance in parallel with the circuit element across which the potential difference is being measured.

(*b*) True. An ideal ammeter would have zero resistance. An ammeter consists of a very small resistance in parallel with a galvanometer movement. The small resistance accomplishes two purposes: 1) It protects the galvanometer movement by shunting most of the current in the circuit around the galvanometer movement, and 2) It minimizes the loading of the circuit by the ammeter by minimizing the resistance of the ammeter.

(*c*) True. An ideal voltage source would have zero internal resistance. The terminal potential difference of a voltage source is given by $V = \mathcal{E} - Ir,$ where $\mathcal{E}$ is the emf of the source, I is the current drawn from the source, and r is the internal resistance of the source.

20 • Before you and your classmates run an experiment, your professor lectures about safety. She reminds you that to measure the voltage across a resistor you connect a voltmeter in parallel with the resistor, and to measure the current in a resistor you connect an ammeter in series with the resistor. She also states that connecting a voltmeter in series with a resistor will not measure the voltage across the resistor, but also cannot do any damage to the circuit or the instrument. In addition, connecting an ammeter in parallel with a resistor will not measure the current in the resistor, but could cause significant damage to the circuit and the instrument. Explain why connecting a voltmeter in series with a resistor causes no damage while connecting an ammeter in parallel with a resistor can cause significant damage.

Determine the Concept Because of the voltmeter's high resistance, if you connect a voltmeter in series with a circuit element, the current, both in the voltmeter and in the rest of the circuit, will be very small. This means that there is little chance of heating the voltmeter and causing damage. However, because of the ammeter's low resistance, if you connect an ammeter in parallel with a circuit element, the current, both in the ammeter and in the entire circuit, excluding any elements in parallel with the ammeter, will be very large. This means that there is a good chance of overheating and causing damage, maybe even a fire. For this reason, ammeters are often equipped with fuses or circuit breakers.

21 • The capacitor in Figure 25-49 is initially uncharged. Just after the switch S is closed, (*a*) the voltage across C equals $\mathcal{E}$, (*b*) the voltage across R equals $\mathcal{E}$, (*c*) the current in the circuit is zero, (*d*) both (*a*) and (*c*) are correct.

Determine the Concept If we apply Kirchhoff's loop rule with the switch closed, we obtain $\mathcal{E} - IR - V_C = 0$. Immediately after the switch is closed, $I = I_{\max}$ and $V_C = 0$. Hence $\mathcal{E} = I_{\max} R$. $\boxed{(b)}$ is correct.

22 •• A capacitor is discharging through a resistor. If it takes a time T for the charge on a capacitor to drop to half its initial value, how long (in terms of T) does it take for the stored energy to drop to half its initial value?

Picture the Problem We can express the variation of charge on the discharging capacitor as a function of time to find the time T it takes for the charge on the capacitor to drop to half its initial value. We can also express the energy remaining in the electric field of the discharging capacitor as a function of time and find the time t' for the energy to drop to half its initial value in terms of T.

Express the time-dependence of the charge stored on a capacitor:

$$Q(t) = Q_0 e^{-t/\tau}$$

where $\tau = RC$.

For $Q(t) = \frac{1}{2}Q_0$:

$$\tfrac{1}{2}Q_0 = Q_0 e^{-T/\tau} \text{ or } \tfrac{1}{2} = e^{-T/\tau}$$

Take the natural logarithm of both sides of the equation and solve for T to obtain:

$$T = \tau \ln(2)$$

Express the dependence of the energy stored in a capacitor on the potential difference V_C across its terminals:

$$U(t) = \tfrac{1}{2}CV_C^2 \qquad (1)$$

Express the potential difference across a discharging capacitor as a function of time:

$$V_C = V_0 e^{-t/RC}$$

Substitute for V_C in equation (1) and simplify to obtain:

$$U(t) = \tfrac{1}{2}C\left(V_0 e^{-t/RC}\right)^2 = \tfrac{1}{2}CV_0^2 e^{-2t/RC} = U_0 e^{-2t/RC}$$

For $U(t) = \frac{1}{2}U_0$:

$$\tfrac{1}{2}U_0 = U_0 e^{-2t'/RC} \Rightarrow \tfrac{1}{2} = e^{-2t'/RC}$$

Take the natural logarithm of both sides of the equation and solve for t' to obtain:

$$t' = \tfrac{1}{2}\tau \ln(2) = \boxed{\tfrac{1}{2}T}$$

23 •• [SSM] In Figure 25-50, the values of the resistances are related as follows: $R_2 = R_3 = 2R_1$. If power P is delivered to R_1, what is the power delivered to R_2 and R_3?

Determine the Concept The power delivered to a resistor varies with the square of the current in the resistor and is directly proportional to the resistance of the resistor ($P = I^2R$).

The power delivered to R_1 is: $P = I_1^2 R_1$

The power delivered to R_2 is: $P_2 = I_2^2 R_2 = I_2^2(2R_1)$

Because $R_2 = R_3$: $I_2 = I_3 = \frac{1}{2}I_1$

Substituting for I_2 and simplifying gives: $P_2 = \left(\frac{1}{2}I_1\right)^2(2R_1) = \frac{1}{2}I_1^2R_1 = \boxed{\frac{1}{2}P}$

Similarly: $P_3 = I_3^2R_3 = \left(\frac{1}{2}I_1\right)^2(2R_1) = \frac{1}{2}I_1^2R_1 = \boxed{\frac{1}{2}P}$

24 •• The capacitor in Figure 25-49 is initially uncharged. The switch *S* is closed and remains closed for a very long time. During this time, (*a*) the energy supplied by the battery is $\frac{1}{2}C\mathcal{E}^2$, (*b*) the energy dissipated in the resistor is $\frac{1}{2}C\mathcal{E}^2$, (*c*) energy in the resistor is dissipated at a constant rate, (*d*) the total charge passing through the resistor is $\frac{1}{2}C\mathcal{E}$.

Determine the Concept The energy stored in the fully charged capacitor is $U = \frac{1}{2}C\mathcal{E}^2$. During the charging process, a total charge $Q_f = \mathcal{E}C$ flows through the battery. The battery therefore does work $W = Q_f\mathcal{E} = C\mathcal{E}^2$. The energy dissipated in the resistor is the difference between W and U. $\boxed{(b)}$ is correct.

Estimation and Approximation

25 •• It is not a good idea to stick the ends of a paper clip into the two rectangular slots of a household electrical wall outlet in the United States. Explain why by estimating the current that a paper clip would carry until either the fuse blows or the breaker trips.

Picture the Problem The current drawn by the paper clip is the ratio of the potential difference (120 V) between the two holes and the resistance of the paper clip. We can use $R = \rho L/A$ to find the resistance of the paper clip. Paper clips are made of steel, which has a resistivity in the range 10 to 100 × 10^{-8} Ω· m,

From the definition of resistance: $I = \frac{\mathcal{E}}{R}$

The resistance of the paper clip is given by:

$$R = \rho\frac{L}{A}$$

Substituting for R in the expression for I and simplifying yields

$$I = \frac{\mathcal{E}}{\rho\frac{L}{A}} = \frac{\mathcal{E}A}{\rho L} = \frac{\mathcal{E}\pi r^2}{\rho L} = \frac{\mathcal{E}\pi d^2}{4\rho L}$$

Assuming that the length of a paper clip is 10 cm and that its diameter is 1.0 mm, substitute numerical values and evaluate I:

$$I = \frac{(120\text{ V})\pi(1.0\text{ mm})^2}{4(50\times10^{-8}\ \Omega\cdot\text{m})(10\text{ cm})} = \boxed{1.9\text{ kA}}$$

26 •• (*a*) Estimate the resistance of an automobile jumper cable. (*b*) Look up the current required to start a typical car. At that current, what is the potential drop that occurs across the jumper cable? (*c*) How much power is dissipated in the jumper cable when it carries this current?

Picture the Problem (*a*) We can use the definition of resistivity to find the resistance of the jumper cable. In Part (*b*), the application of Ohm's law will yield the potential difference across the jumper cable when it is starting a car, and, in Part (*c*), we can use the expression for the power dissipated in a conductor to find the power dissipation in the jumper cable.

(*a*) Noting that a jumper cable has two leads, express the resistance of the cable in terms of the wire's resistivity and the cable's length, and cross-sectional area:

$$R = \rho\frac{L}{A}$$

Assuming the length of the jumper cables to be 3.0 m and its cross-sectional area to be 10 mm^2, substitute numerical values (see Table 25-1 for the resistivity of copper) and evaluate R:

$$R = (1.7\times10^{-8}\ \Omega\cdot\text{m})\frac{3.0\text{ m}}{10\text{ mm}^2}$$
$$= \boxed{5.1\text{ m}\Omega}$$

(*b*) Apply Ohm's law to the cable with a starting current of 90 A to obtain:

$$V = IR = (90\text{ A})(5.1\text{ m}\Omega) = 459\text{ mV}$$
$$= \boxed{0.46\text{ V}}$$

(*c*) Use the expression for the power dissipated in a conductor to obtain:

$$P = IV = (90\,\mathrm{A})(459\,\mathrm{mV}) = \boxed{41\,\mathrm{W}}$$

27 •• Your manager wants you to design a new super-insulated water heater for the residential market. A coil of Nichrome wire is to be used as the heating element. Estimate the length of wire required. *HINT: You will need to determine the size of a typical hot water heater and a reasonable time period for creating hot water.*

Picture the Problem We can combine the expression for the rate at which energy is delivered to the water to warm it ($P = \mathcal{E}^2/R$) and the expression for the resistance of a conductor ($R = \rho L/A$) to obtain an expression for the required length L of Nichrome wire.

From Equation 25-10, the length of Nichrome wire required is given by:

$L = \dfrac{RA}{\rho_{\mathrm{Ni}}}$ where A is the cross-sectional area of the wire.

Use an expression for the power dissipated in a resistor to relate the required resistance to rate at which energy is delivered to generate the warm water:

$$P = \frac{\mathcal{E}^2}{R} \Rightarrow R = \frac{\mathcal{E}^2}{P}$$

Substituting for R and simplifying yields:

$$L = \frac{\mathcal{E}^2 A}{\rho_{\mathrm{Ni}} P}$$

The power required to heat the water is the rate at which the wire will deliver energy to the water:

$$P = \frac{\Delta E}{\Delta t} = \frac{\Delta(mc\Delta T)}{\Delta t} = mc\frac{\Delta T}{\Delta t}$$

Substitute for P to obtain:

$$L = \frac{\mathcal{E}^2 A}{\rho_{\mathrm{Ni}} mc\dfrac{\Delta T}{\Delta t}}$$

The mass of water to be heated is the product of its density and the volume of the water tank:

$m = \rho_{\mathrm{H_2O}} V = \rho_{\mathrm{H_2O}} A'd$

where A' is the cross-sectional area of the water tank.

Finally, substituting for m and simplifying yields:

$$L=\frac{\mathcal{E}^2 A}{\rho_{\text{Ni}}\rho_{\text{H}_2\text{O}}A'dc\dfrac{\Delta T}{\Delta t}}=\frac{\mathcal{E}^2\pi r_{\text{wire}}^2\Delta t}{\rho_{\text{Ni}}\rho_{\text{H}_2\text{O}}\pi r_{\text{tank}}^2 dc\Delta T}=\frac{\mathcal{E}^2 r_{\text{wire}}^2\Delta t}{\rho_{\text{Ni}}\rho_{\text{H}_2\text{O}} r_{\text{tank}}^2 dc\Delta T}$$

The diameter of a typical 40-gal water heater is about 50 cm and its height is approximately 1.3 m. Assume that the diameter of the Nichrome wire is 2.0 mm and that the water, initially at 20°C, is to be heated to 80°C in 1.0 h. Substitute numerical values (see Table 25-1 for the resistivity of Nichrome and Table 18-1 for the heat capacity of water) and evaluate L:

$$L=\frac{(120\,\text{V})^2\left(2.0\times10^{-3}\,\text{m}\right)^2\left(1.0\,\text{h}\times\dfrac{3600\,\text{s}}{\text{h}}\right)}{\left(100\times10^{-8}\,\Omega\cdot\text{m}\right)\left(1000\dfrac{\text{kg}}{\text{m}^3}\right)(0.25\ \text{m})^2(0.50\,\text{m})\left(4.18\dfrac{\text{kJ}}{\text{kg}\cdot\text{C}^\circ}\right)(60\text{C}^\circ)}=\boxed{26\,\text{m}}$$

28 •• A compact fluorescent light bulb costs about \$6.00 each and has a typical lifetime of 10 000 h. These bulbs use 20 W of power, but produce illumination equivalent to that of 75-W incandescent bulbs. An incandescent bulb costs about \$1.50 and has a typical lifetime of 1000 h. Your family wonders whether it should buy fluorescent light bulbs. Estimate the amount of money your household would save each year by using compact fluorescent light bulbs instead of the incandescent bulbs.

Picture the Problem We can find the annual savings by taking into account the costs of the two types of bulbs, the rate at which they consume energy and the cost of that energy, and their expected lifetimes. We'll assume that the household lights are on for an average of 8 hours per day.

Express the yearly savings:

$$\Delta\$=\text{Cost}_{\text{incandescent}}-\text{Cost}_{\text{fluorescent}}\qquad(1)$$

Express the annual costs with the incandescent and fluorescent bulbs:

$$\text{Cost}_{\text{incandescent}}=\text{Cost}_{\text{bulbs}}+\text{Cost}_{\text{energy}}$$

and

$$\text{Cost}_{\text{fluorescent}}=\text{Cost}_{\text{bulbs}}+\text{Cost}_{\text{energy}}$$

The annual cost of the incandescent bulbs is the product of the number of bulbs in use, the annual consumption of bulbs, and the cost per bulb:

$$\text{Cost}_{\text{bulbs}} = (6)\left(\frac{365.24\,\text{d} \times \dfrac{8\,\text{h}}{\text{d}}}{1000\,\text{h}}\right)(\$1.50) = \$26.30$$

The cost of operating the incandescent bulbs for one year is the product of the energy consumed and the cost per unit of energy:

$$\text{Cost}_{\text{energy}} = 6(75\,\text{W})\left(365.24\frac{\text{d}}{\text{y}}\right)\left(\frac{8\,\text{h}}{\text{d}}\right)\left(\frac{\$0.115}{\text{kW}\cdot\text{h}}\right) = \$151.21$$

The annual cost of the fluorescent bulbs is the product of the number of bulbs in use, the annual consumption of bulbs, and the cost per bulb:

$$\text{Cost}_{\text{bulbs}} = (6)\left(\frac{365.24\,\text{d} \times \dfrac{8\,\text{h}}{\text{d}}}{10000\,\text{h}}\right)(\$6) = \$10.52$$

The cost of operating the fluorescent bulbs for one year is the product of the energy consumed and the cost per unit of energy:

$$\text{Cost}_{\text{energy}} = 6(20\,\text{W})\left(365.24\,\text{d} \times \frac{8\,\text{h}}{\text{d}}\right)\left(\frac{\$0.115}{\text{kW}\cdot\text{h}}\right) = \$40.32$$

Substitute in equation (1) and evaluate the cost savings Δ$:

$$\begin{aligned}\Delta\$ &= \text{Cost}_{\text{incandescent}} - \text{Cost}_{\text{fluorescent}} = (\$26.30 + \$151.20) - (\$10.52 + \$40.32) \\ &= \boxed{\$127}\end{aligned}$$

29 •• The wires in a house must be large enough in diameter so that they do not get hot enough to start a fire. While working for a building contractor during the summer, you are involved in remodeling a house. The local building code states that the joule heating of the wire used in houses should not exceed 2.0 W/m. Estimate the maximum gauge of the copper wire that you can use during the rewiring of the house with 20-A circuits.

Picture the Problem We can use an expression for the power dissipated in a resistor to relate the Joule heating in the wire to its resistance and the definition of resistivity to relate the resistance to the length and cross-sectional area of the wire. We can find the diameter of the wire from its cross-sectional area and then use Table 25-2 to find the maximum gauge you can use during the rewiring of the house.

Express the power the wires must dissipate in terms of the current they carry and their resistance:

$$P = I^2 R$$

Divide both sides of the equation by L to express the power dissipation per unit length:

$$\frac{P}{L} = \frac{I^2 R}{L}$$

The resistance of the wire is given by:

$$R = \rho\frac{L}{A} = \rho\frac{L}{\frac{\pi}{4}d^2} = \frac{4\rho L}{\pi d^2}$$

Substitute for R to obtain:

$$\frac{P}{L} = \frac{4\rho I^2}{\pi d^2} \Rightarrow d = 2I\sqrt{\frac{\rho}{\pi(P/L)}}$$

Substitute numerical values (see Table 25-1 for the resistivity of copper wire) and evaluate d:

$$d = 2(20\,\text{A})\sqrt{\frac{1.7\times10^{-8}\,\Omega\cdot\text{m}}{\pi(2.0\,\text{W/m})}} = 2.1\,\text{mm}$$

Consulting Table 25-2, we note that the maximum gauge you can use is $\boxed{12}$.

30 •• A laser diode used in making a laser pointer is a highly nonlinear circuit element. Its behavior is as follows: for any voltage drop across it that is less than about 2.30 V, it behaves as if it has an infinite internal resistance, but for voltages higher than 2.30 V it has a very low internal resistance—effectively zero. (*a*) A laser pointer is made by putting two 1.55 V watch batteries in series across the laser diode. If the batteries each have an internal resistance between 1.00 Ω and 1.50 Ω, estimate the current in the laser beam. (*b*) About half of the power delivered to the laser diode goes into radiant energy. Using this fact, estimate the power of the laser beam, and compare this value to typical quoted values of about 3.00 mW. (*c*) If the batteries each have a capacity of 20.0-mA·h (i.e., they can deliver a constant current of 20.0 mA for approximately one hour before discharging), estimate how long one can continuously operate the laser pointer before replacing the batteries.

Picture the Problem Let r be the internal resistance of each battery and apply Kirchhoff's loop rule to the circuit consisting of the two batteries and the laser diode to relate the current in laser diode to r and the potential differences across the batteries and the diode. We can find the power of the laser diode from the product of the potential difference across the internal resistance of the batteries and the current I delivered by them and the time-to-discharge from the combined capacities of the two batteries and I.

(*a*) Apply Kirchhoff's loop rule to the circuit consisting of the two batteries and the laser diode to obtain:

$$2\mathcal{E} - 2Ir - V_{\substack{\text{laser}\\ \text{diode}}} = 0$$

Solving for I yields:

$$I = \frac{\mathcal{E} - V_{\substack{\text{laser}\\ \text{diode}}}}{2r}$$

Assuming that $r = 125\ \Omega$, substitute numerical values and evaluate I:

$$I = \frac{2(1.55) - 2.30\,\text{V}}{2(125\,\Omega)} = 3.20\,\text{mA}$$
$$= \boxed{3.2\,\text{mA}}$$

(*b*) The power delivered by the batteries is given by:

$$P = IV = (3.20\,\text{mA})(2.30\,\text{V}) = 7.36\,\text{mW}$$

The power of the laser is half this value:

$$P_{\text{laser}} = \tfrac{1}{2}P = \tfrac{1}{2}(7.36\,\text{mW}) = 3.68\,\text{mW}$$
$$= \boxed{3.7\,\text{mW}}$$

Express the ratio of P_{laser} to P_{quoted}:

$$\frac{P_{\text{laser}}}{P_{\text{quoted}}} = \frac{3.68\,\text{mW}}{3.00\,\text{mW}} = 1.23$$

or

$$P_{\text{laser}} = \boxed{1.23P_{\text{quoted}}}$$

(*c*) Express the time-to-discharge:

$$\Delta t_{\text{discharge}} = \frac{\text{Capacity}}{I}$$

Because each battery has a capacity of 20.0 mA·h, the series combination has a capacity of 40.0 mA·h and:

$$\Delta t_{\text{discharge}} = \frac{40.0\,\text{mA}\cdot\text{h}}{3.20\,\text{mA}} \approx \boxed{12.5\,\text{h}}$$

Current, Current Density, Drift Speed and the Motion of Charges

31 • [SSM] A 10-gauge copper wire carries a current equal to 20 A. Assuming copper has one free electron per atom, calculate the drift speed of the free electrons in the wire.

Picture the Problem We can relate the drift velocity of the electrons to the current density using $I = nev_\text{d}A$. We can find the number density of charge carriers n using $n = \rho N_\text{A}/M$, where ρ is the mass density, N_A Avogadro's number, and M the molar mass. We can find the cross-sectional area of 10-gauge wire in Table 25-2.

Use the relation between current and drift velocity to relate I and n:

$$I = nev_\text{d}A \Rightarrow v_\text{d} = \frac{I}{neA}$$

The number density of charge carriers n is related to the mass density ρ, Avogadro's number N_A, and the molar mass M:

$$n = \frac{\rho N_\text{A}}{M}$$

For copper, $\rho = 8.93\ \text{g/cm}^3$ and $M = 63.55$ g/mol. Substitute and evaluate n:

$$n = \frac{(8.93\,\text{g/cm}^3)(6.022\times10^{23}\ \text{atoms/mol})}{63.55\,\text{g/mol}}$$

$$= 8.459\times10^{28}\ \text{atoms/m}^3$$

Using Table 25-2, find the cross-sectional area of 10-gauge wire:

$$A = 5.261\,\text{mm}^2$$

Substitute numerical values and evaluate v_d:

$$v_\text{d} = \frac{20\,\text{A}}{(8.459\times10^{28}\ \text{m}^{-3})(1.602\times10^{-19}\ \text{C})(5.261\text{mm}^2)} = \boxed{0.28\,\text{mm/s}}$$

32 •• A thin nonconducting ring that has a radius a and a linear charge density λ rotates with angular speed ω about an axis through its center and perpendicular to the plane of the ring. Find the current of the ring.

Picture the Problem We can use the definition of current, the definition of charge density, and the relationship between period and frequency to derive an expression for the current as a function of a, λ, and ω.

Use the definition of current to relate the charge ΔQ associated with a segment of the ring to the time Δt it takes the segment to pass a given point:

$$I = \frac{\Delta Q}{\Delta t}$$

Because each segment carries a charge ΔQ and the time for one revolution is T:

$$I = \frac{\Delta Q}{T} = \Delta Q f \qquad (1)$$

Use the definition of the charge density λ to relate the charge ΔQ to the radius a of the ring:

$$\lambda = \frac{\Delta Q}{2\pi a} \Rightarrow \Delta Q = 2\pi a\lambda$$

Substitute for ΔQ in equation (1) to obtain:

$$I = 2\pi a\lambda f$$

Because $\omega = 2\pi f$:

$$I = \boxed{a\lambda\omega}$$

33 •• **[SSM]** A length of 10-gauge copper wire and a length of 14-gauge copper wire are welded together end to end. The wires carry a current of 15 A. (*a*) If there is one free electron for each copper atom in each wire, find the drift speed of the electrons in each wire. (*b*) What is the ratio of the magnitude of the current density in the length of10-gauge wire to the magnitude of the current density in the length of 14-gauge wire?

Picture the Problem (*a*) The current will be the same in the two wires and we can relate the drift velocity of the electrons in each wire to their current densities and the cross-sectional areas of the wires. We can find the number density of charge carriers n using $n = \rho N_\text{A}/M$, where ρ is the mass density, N_A Avogadro's number, and M the molar mass. We can find the cross-sectional area of 10- and 14-gauge wires in Table 25-2. In Part (*b*) we can use the definition of current density to find the ratio of the magnitudes of the current densities in the 10-gauge and 14-gauge wires.

(*a*) Relate the current density to the drift velocity of the electrons in the 10-gauge wire:

$$\frac{I_{10\text{ gauge}}}{A_{10\text{ gauge}}} = nev_{\text{d},10} \Rightarrow v_{\text{d},10} = \frac{I_{10\text{ gauge}}}{neA_{10\text{ gauge}}}$$

The number density of charge carriers n is related to the mass density ρ, Avogadro's number N_A, and the molar mass M:

$$n = \frac{\rho N_A}{M}$$

For copper, $\rho = 8.93\ \text{g/cm}^3$ and $M = 63.55$ g/mol. Substitute numerical values and evaluate n:

$$n = \frac{\left(8.93\,\frac{\text{g}}{\text{cm}^3}\right)\left(6.022\times10^{23}\,\frac{\text{atoms}}{\text{mol}}\right)}{63.55\,\frac{\text{g}}{\text{mol}}} = 8.462\times10^{28}\,\frac{\text{atoms}}{\text{m}^3}$$

Use Table 25-2 to find the cross-sectional area of 10-gauge wire:

$$A_{10} = 5.261\,\text{mm}^2$$

Substitute numerical values and evaluate $v_{d.10}$:

$$v_{d,10} = \frac{15\,\text{A}}{\left(8.462\times10^{28}\,\text{m}^{-3}\right)\left(1.602\times10^{-19}\,\text{C}\right)\left(5.261\,\text{mm}^2\right)} = 0.210\,\text{mm/s} = \boxed{0.21\,\text{mm/s}}$$

Express the continuity of the current in the two wires:

$$I_{10\,\text{gauge}} = I_{14\,\text{gauge}}$$

or

$$nev_{d,10}A_{10\,\text{gauge}} = nev_{d,14}A_{14\,\text{gauge}}$$

Solve for $v_{d,14}$ to obtain:

$$v_{d,14} = v_{d,10}\frac{A_{10\,\text{gauge}}}{A_{14\,\text{gauge}}}$$

Use Table 25-2 to find the cross-sectional area of 14-gauge wire:

$$A_{14} = 2.081\,\text{mm}^2$$

Substitute numerical values and evaluate $v_{d,14}$:

$$v_{d,14} = (0.210\,\text{mm/s})\frac{5.261\,\text{mm}^2}{2.081\,\text{mm}^2} = \boxed{0.53\,\text{mm/s}}$$

(*b*) The ratio of current density, 10-gauge wire to 14-gauge wire, is given by:

$$\frac{J_{10}}{J_{14}} = \frac{\frac{I_{10}}{A_{10}}}{\frac{I_{14}}{A_{14}}} = \frac{I_{10}A_{14}}{I_{14}A_{10}}$$

Because $I_{10} = I_{14}$:

$$\frac{J_{10}}{J_{14}} = \frac{A_{14}}{A_{10}}$$

Substitute numerical values and evaluate $\frac{J_{10}}{J_{14}}$:

$$\frac{J_{10}}{J_{14}} = \frac{2.081\,\text{mm}^2}{5.261\,\text{mm}^2} = \boxed{0.396}$$

34 •• An accelerator produces a beam of protons with a circular cross section that is 2.0 mm in diameter and has a current of 1.0 mA. The current density is uniformly distributed through the beam. The kinetic energy of each proton is 20 MeV. The beam strikes a metal target and is absorbed by the target. (*a*) What is the number density of the protons in the beam? (*b*) How many protons strike the target each minute? (*c*) What is the magnitude of the current density in this beam?

Picture the Problem We can use $I = neAv$ to relate the number n of protons per unit volume in the beam to current I. We can find the speed of the particles in the beam from their kinetic energy. In Part (*b*) we can express the number of protons N striking the target per unit time as the product of the number of protons per unit volume n in the beam and the volume of the cylinder containing those protons that will strike the target in an elapsed time Δt and solve for N. Finally, we can use the definition of current to express the charge arriving at the target as a function of time.

(*a*) Use the relation between current and drift velocity (Equation 25-3) to relate I and n:

$$I = neAv \Rightarrow n = \frac{I}{eAv}$$

The kinetic energy of the protons is given by:

$$K = \tfrac{1}{2}m_{\text{p}}v^2 \Rightarrow v = \sqrt{\frac{2K}{m_{\text{p}}}}$$

Relate the cross-sectional area A of the beam to its diameter D:

$$A = \tfrac{1}{4}\pi D^2$$

Substitute for v and A and simplify to obtain:

$$n = \frac{I}{\tfrac{1}{4}\pi e D^2\sqrt{\frac{2K}{m_{\text{p}}}}} = \frac{4I}{\pi e D^2}\sqrt{\frac{m_{\text{p}}}{2K}}$$

Substitute numerical values and evaluate n:

$$n = \frac{4(1.0\,\text{mA})}{\pi(1.602\times10^{-19}\,\text{C})(2\,\text{mm})^2}\sqrt{\frac{1.673\times10^{-27}\,\text{kg}}{2(20\,\text{MeV})(1.602\times10^{-19}\,\text{J/eV})}}$$
$$= 3.21\times10^{13}\,\text{m}^{-3} = \boxed{3.2\times10^{13}\,\text{m}^{-3}}$$

(b) Express the number of protons N striking the target per unit time as the product of the number n of protons per unit volume in the beam and the volume of the cylinder containing those protons that will strike the target in an elapsed time Δt and solve for N:

$$\frac{N}{\Delta t} = n(vA) \Rightarrow N = nvA\Delta t$$

Substitute for v and A to obtain:

$$N = \tfrac{1}{4}\pi D^2 n\Delta t\sqrt{\frac{2K}{m_\text{p}}}$$

Substitute numerical values and evaluate N:

$$N = \tfrac{1}{4}\pi(2\,\text{mm})^2(3.21\times10^{13}\,\text{m}^{-3})(1\,\text{min})\sqrt{\frac{2(20\,\text{MeV})(1.602\times10^{-19}\,\text{J/eV})}{1.673\times10^{-27}\,\text{kg}}}$$
$$= \boxed{3.7\times10^{17}}$$

(c) The magnitude of the current density in this beam is given by:

$$J = \frac{I}{A} = \frac{1.0\,\text{mA}}{\pi(1.0\times10^{-3}\,\text{m})^2}$$
$$= \boxed{0.32\,\text{kA/m}^2}$$

35 •• [SSM] In one of the colliding beams of a planned proton *supercollider*, the protons are moving at nearly the speed of light and the beam current is 5.00-mA. The current density is uniformly distributed throughout the beam. (a) How many protons are there per meter of length of the beam? (b) If the cross-sectional area of the beam is 1.00 x 10^{-6} m^2, what is the number density of protons? (c) What is the magnitude of the current density in this beam?

Picture the Problem We can relate the number of protons per meter N to the number n of free charge-carrying particles per unit volume in a beam of cross-sectional area A and then use the relation between current and drift velocity to relate n to I.

(*a*) Express the number of protons per meter N in terms of the number n of free charge-carrying particles per unit volume in a beam of cross-sectional area A:

$$N = nA \qquad (1)$$

Use the relation between current and drift velocity to relate I and n:

$$I = enAv \Rightarrow n = \frac{I}{eAv}$$

Substitute for n and simplify to obtain:

$$N = \frac{IA}{eAv} = \frac{I}{ev}$$

Substitute numerical values and evaluate N:

$$N = \frac{5.00\,\text{mA}}{\left(1.602\times10^{-19}\ \text{C}\right)\left(2.998\times10^{8}\ \text{m/s}\right)} = 1.041\times10^{8}\ \text{m}^{-1} = \boxed{1.04\times10^{8}\ \text{m}^{-1}}$$

(*b*) From equation (1) we have:

$$n = \frac{N}{A} = \frac{1.041\times10^{8}\ \text{m}^{-1}}{1.00\times10^{-6}\ \text{m}^{2}} = \boxed{1.04\times10^{14}\ \text{m}^{-3}}$$

(*c*) The magnitude of the current density in this beam is given by:

$$J = \frac{I}{A} = \frac{5.00\ \text{mA}}{1.00\times10^{-6}\,\text{m}^{2}} = \boxed{5.00\,\text{kA/m}^{2}}$$

36 •• The *solar wind* consists of protons from the Sun moving toward Earth (the wind actually consists of about 95% protons). The number density of protons at a distance from the Sun equal to the orbital radius of Earth is about 7.0 protons per cubic centimeter. Your research team monitors a satellite that is in orbit around the Sun at a distance from the Sun equal to equal to Earth's orbital radius. You are in charge of the satellite's *mass spectrometer*, an instrument used to measure the composition and intensity of the solar wind. The aperture of your spectrometer is a circle of radius 25 cm. The rate of collection of protons by the spectrometer is such that they constitute a measured current of 85 nA. What is the speed of the protons in the solar wind? (Assume the protons enter the aperture at normal incidence.)

Picture the Problem We can use Equation 25-3 to express the drift speed of the protons in the solar wind in terms of the proton current, the number density of the protons, and the cross-sectional area of the aperture of the spectrometer.

From Equation 25-3, the drift speed of the protons in the solar winds is given by:

$$v_d = \frac{I}{qnA}$$

Substitute numerical values and evaluate v_d:

$$v_d = \frac{85\ \text{nA}}{\left(1.602\times10^{-19}\ \text{C}\right)\left(\dfrac{7.0}{\text{cm}^3}\right)\pi\left(25\ \text{cm}\right)^2} = \boxed{3.9\times10^5\ \text{m/s}}$$

37 •• A gold wire has a 0.10-mm-diameter cross section. Opposite ends of this wire are connected to the terminals of a 1.5-V battery. If the length of the wire is 7.5 cm, how much time, on average, is required for electrons leaving the negative terminal of the battery to reach the positive terminal? Assume the resistivity of gold is $2.44\times10^{-8}\ \Omega\cdot\text{m}$.

Picture the Problem We can use the definition of average speed, Equation 25-3 ($I = qnAv_d$), Equation 25-10 ($R = \rho L/A$) and the relationship between the number density of electrons, Avogadro's number, and the molar mass of gold to derive an expression for the average travel time of the electrons.

The average transit time for the electrons is the ratio of the distance they travel to their drift speed:

$\Delta t = \dfrac{L}{v_d}$ where L is the length of the gold wire.

From Equation 25-3:

$$v_d = \frac{I}{qnA}$$

Substituting for v_d and I and simplifying yields:

$$\Delta t = \frac{L}{\dfrac{I}{qnA}} = \frac{qnAL}{\dfrac{V}{R}} = \frac{qnALR}{V}$$

Use Equation 25-10 to express the resistance of the gold wire:

$$R = \rho_{Au}\frac{L}{A}$$

Substitute for R and simplify to obtain:

$$\Delta t = \frac{qnAL\rho_{Au}\dfrac{L}{A}}{V} = \frac{qnL^2\rho_{Au}}{V}$$

The number density of free electrons is given by:

$$n = \left(\frac{\text{mass}}{\text{molar mass}}\right)\left(\frac{1}{\text{volume}}\right)N_A$$

$$= \left(\frac{\rho_{\text{density, Au}}}{M_{\text{mol, Au}}}\right)N_A = \left(\frac{N_A}{M_{\text{mol, Au}}}\right)\rho_{\text{density, Au}}$$

Finally, substituting for n yields:

$$\Delta t = \frac{q\left(\dfrac{N_A}{M_{\text{mol, Au}}}\right)\rho_{\text{density, Au}} L^2 \rho_{\text{Au}}}{V}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \left(1.602\times10^{-19}\ \text{C}\right)\left(\frac{6.022\times10^{23}\ \text{mol}^{-1}}{0.19697\,\dfrac{\text{kg}}{\text{mol}}}\right)\left(19.3\times10^{3}\,\frac{\text{kg}}{\text{m}^3}\right)(7.5\ \text{cm})^2$$
$$\times\frac{\left(2.44\times10^{-8}\ \Omega\cdot\text{m}\right)}{1.5\ \text{V}} = \boxed{0.86\ \text{s}}$$

Resistance, Resistivity and Ohm’s Law

38 • A 10-m-long wire has a resistance equal to 0.20 Ω and carries a current equal to 5.0 A. (*a*) What is the potential difference across the entire length of the wire? (*b*) What is the electric-field strength in the wire?

Picture the Problem We can use Ohm’s law to find the potential difference between the ends of the wire and $V = EL$ to find the magnitude of the electric field in the wire.

(*a*) Apply Ohm’s law to obtain:

$$V = RI = (0.20\,\Omega)(5.0\ \text{A}) = \boxed{1.0\ \text{V}}$$

(*b*) Relate the electric field to the potential difference across the wire and the length of the wire:

$$E = \frac{V}{L} = \frac{1.0\ \text{V}}{10\ \text{m}} = \boxed{0.10\ \text{V/m}}$$

39 • **[SSM]** A potential difference of 100 V across the terminals of a resistor produces a current of 3.00 A in the resistor. (*a*) What is the resistance of the resistor? (*b*) What is the current in the resistor when the potential difference is only 25.0 V? (Assume the resistance of the resistor remains constant.)

Picture the Problem We can apply Ohm’s law to both parts of this problem, solving first for R and then for I.

(*a*) Apply Ohm's law to obtain:

$$R = \frac{V}{I} = \frac{100\,\text{V}}{3.00\,\text{A}} = \boxed{33.3\,\Omega}$$

(*b*) Apply Ohm's law a second time to obtain:

$$I = \frac{V}{R} = \frac{25.0\,\text{V}}{33.3\,\Omega} = \boxed{0.750\,\text{A}}$$

40 • A block of carbon is 3.0 cm long and has a square cross-section whose sides are 0.50-cm long. A potential difference of 8.4 V is maintained across its length. (*a*) What is the resistance of the block? (*b*) What is the current in this resistor?

Picture the Problem We can use $R = \rho L/A$ to find the resistance of the block and Ohm's law to find the current in it for the given potential difference across its length.

(*a*) Relate the resistance of the block to its resistivity ρ, cross-sectional area A, and length L:

$$R = \rho\frac{L}{A}$$

Substitute numerical values (see Table 25-1 for the resistivity of carbon) and evaluate R:

$$R = \left(3500\times10^{-8}\,\Omega\cdot\text{m}\right)\frac{3.0\,\text{cm}}{(0.50\,\text{cm})^2}$$

$$= 42.0\,\text{m}\Omega = \boxed{42\,\text{m}\Omega}$$

(*b*) Apply Ohm's law to obtain:

$$I = \frac{V}{R} = \frac{8.4\,\text{V}}{42.0\,\text{m}\Omega} = \boxed{0.20\,\text{kA}}$$

41 • **[SSM]** An extension cord consists of a pair of 30-m-long 16-gauge copper wires. What is the potential difference that must be applied across one of the wires if it is to carry a current of 5.0 A?

Picture the Problem We can use Ohm's law in conjunction with $R = \rho L/A$ to find the potential difference across one wire of the extension cord.

Using Ohm's law, express the potential difference across one wire of the extension cord:

$$V = IR$$

Relate the resistance of the wire to its resistivity ρ, cross-sectional area A, and length L:

$$R = \rho\frac{L}{A}$$

Substitute for R to obtain:

$$V = \rho \frac{LI}{A}$$

Substitute numerical values (see Table 25-1 for the resistivity of copper and Table 25-2 for the cross-sectional area of 16-gauge wire) and evaluate V:

$$V = \left(1.7\times10^{-8}\ \Omega\cdot\text{m}\right)\frac{(30\,\text{m})(5.0\,\text{A})}{1.309\,\text{mm}^2}$$
$$= \boxed{1.9\,\text{V}}$$

42 • (*a*) How long is a 14-gauge copper wire that has a resistance of 12.0 Ω? (*b*) How much current will it carry if a 120-V potential difference is applied across its length?

Picture the Problem We can use $R = \rho L/A$ to find the length of a 14-gauge copper wire that has a resistance of 12.0 Ω and Ohm's law to find the current in the wire.

(*a*) Relate the resistance of the wire to its resistivity ρ, cross-sectional area A, and length L:

$$R = \rho\frac{L}{A} \Rightarrow L = \frac{RA}{\rho}$$

Substitute numerical values (see Table 25-1 for the resistivity of copper and Table 25-2 for the cross-sectional area of 14-gauge wire) and evaluate L:

$$L = \frac{(12.0\,\Omega)\left(2.081\,\text{mm}^2\right)}{1.7\times10^{-8}\ \Omega\cdot\text{m}} = \boxed{1.5\,\text{km}}$$

(*b*) Apply Ohm's law to find the current in the wire:

$$I = \frac{V}{R} = \frac{120\ \text{V}}{12.0\,\Omega} = \boxed{10.0\ \text{A}}$$

43 • A cylinder of glass is 1.00 cm long and has a resistivity of 1.01×10^{12} Ω·m. What length of copper wire that has the same cross-sectional area will have the same resistance as the glass cylinder?

Picture the Problem We can use $R = \rho L/A$ to express the resistances of the glass cylinder and the copper wire. Expressing their ratio will eliminate the common cross-sectional areas and leave us with an expression we can solve for the length of the copper wire.

Relate the resistance of the glass cylinder to its resistivity, cross-sectional area, and length:

$$R_{\text{glass}} = \rho_{\text{glass}}\frac{L_{\text{glass}}}{A_{\text{glass}}}$$

Relate the resistance of the copper wire to its resistivity, cross-sectional area, and length:

$$R_{\text{Cu}} = \rho_{\text{Cu}} \frac{L_{\text{Cu}}}{A_{\text{Cu}}}$$

Divide the second of these equations by the first to obtain:

$$\frac{R_{\text{Cu}}}{R_{\text{glass}}} = \frac{\rho_{\text{Cu}} \dfrac{L_{\text{Cu}}}{A_{\text{Cu}}}}{\rho_{\text{glass}} \dfrac{L_{\text{glass}}}{A_{\text{glass}}}} = \frac{\rho_{\text{Cu}}}{\rho_{\text{glass}}} \cdot \frac{L_{\text{Cu}}}{L_{\text{glass}}}$$

Because $A_{\text{glass}} = A_{\text{Cu}}$ and $R_{\text{Cu}} = R_{\text{glass}}$:

$$1 = \frac{\rho_{\text{Cu}}}{\rho_{\text{glass}}} \cdot \frac{L_{\text{Cu}}}{L_{\text{glass}}} \Rightarrow L_{\text{Cu}} = \frac{\rho_{\text{glass}}}{\rho_{\text{Cu}}} L_{\text{glass}}$$

Substitute numerical values (see Table 25-1 for the resistivities of glass and copper) and evaluate L_{Cu}:

$$L_{\text{Cu}} = \frac{1.01\times10^{12}\ \Omega\cdot\text{m}}{1.7\times10^{-8}\ \Omega\cdot\text{m}}(1.00\,\text{cm})$$

$$= \boxed{5.94\times10^{17}\ \text{m}} \times \frac{1\,c\cdot\text{y}}{9.461\times10^{15}\ \text{m}}$$

$$= \boxed{63\,c\cdot\text{y}}$$

44 •• While remodeling your garage, you need to temporarily splice, end to end, an 80-m-long copper wire that is 1.00 mm in diameter with a 49-m-long aluminum wire that has the same diameter. The maximum current in the wires is 2.00 A. (*a*) Find the potential drop across each wire of this system when the current is 2.00 A. (*b*) Find the electric field in each wire when the current is 2.00 A.

Picture the Problem We can use Ohm's law to relate the potential differences across the two wires to their resistances and $R = \rho L/A$ to relate their resistances to their lengths, resistivities, and cross-sectional areas. Once we've found the potential differences across each wire, we can use $E = V/L$ to find the electric field in each wire.

(*a*) Apply Ohm's law to express the potential drop across each wire:

$$V_{\text{Cu}} = IR_{\text{Cu}} \text{ and } V_{\text{Fe}} = IR_{\text{Fe}}$$

Relate the resistances of the wires to their resistivity, cross-sectional area, and length:

$$R_{\text{Cu}} = \rho_{\text{Cu}} \frac{L_{\text{Cu}}}{A_{\text{Cu}}} \text{ and } R_{\text{Fe}} = \rho_{\text{Cu}} \frac{L_{\text{Fe}}}{A_{\text{Fe}}}$$

Substitute for R_{Cu} and R_{Fe} to obtain:

$$V_{\text{Cu}} = \frac{\rho_{\text{Cu}} l_{\text{Cu}}}{A_{\text{Cu}}} I \text{ and } V_{\text{Fe}} = \frac{\rho_{\text{Fe}} l_{\text{Fe}}}{A_{\text{Fe}}} I$$

Substitute numerical values (see Table 25-1 for the resistivities of copper and iron) and evaluate the potential differences:

$$V_{\text{Cu}} = \frac{(1.7\times10^{-8}\ \Omega\cdot\text{m})(80\ \text{m})}{\frac{1}{4}\pi(1.00\ \text{mm})^2}(2.00\ \text{A}) = 3.463\ \text{V} = \boxed{3.5\ \text{V}}$$

and

$$V_{\text{Fe}} = \frac{(10\times10^{-8}\ \Omega\cdot\text{m})(49\ \text{m})}{\frac{1}{4}\pi(1.00\ \text{mm})^2}(2.00\ \text{A}) = 12.48\ \text{V} = \boxed{12\ \text{V}}$$

(*b*) Express the electric field in each conductor in terms of its length and the potential difference across it:

$$E_{\text{Cu}} = \frac{V_{\text{Cu}}}{l_{\text{Cu}}} \text{ and } E_{\text{Fe}} = \frac{V_{\text{Fe}}}{l_{\text{Fe}}}$$

Substitute numerical values and evaluate the electric fields:

$$E_{\text{Cu}} = \frac{3.463\ \text{V}}{80\ \text{m}} = \boxed{43\ \text{mV/m}}$$

and

$$E_{\text{Fe}} = \frac{12.48\ \text{V}}{49\ \text{m}} = \boxed{0.25\ \text{V/m}}$$

45 •• [SSM] A 1.00-m-long wire has a resistance equal to 0.300 Ω. A second wire made of identical material has a length of 2.00 m and a mass equal to the mass of the first wire. What is the resistance of the second wire?

Picture the Problem We can use $R = \rho L/A$ to relate the resistance of the wires to their lengths, resistivities, and cross-sectional areas. To find the resistance of the second wire, we can use the fact that the volumes of the two wires are the same to relate the cross-sectional area of the first wire to the cross-sectional area of the second wire.

Relate the resistance of the first wire to its resistivity, cross-sectional area, and length:

$$R = \rho\frac{L}{A}$$

Relate the resistance of the second wire to its resistivity, cross-sectional area, and length:

$$R' = \rho\frac{L'}{A'}$$

Divide the second of these equations by the first to obtain:

$$\frac{R'}{R}=\frac{\rho\frac{L'}{A'}}{\rho\frac{L}{A}}=\frac{L'}{L}\frac{A}{A'}\Rightarrow R'=2\frac{A}{A'}R \quad (1)$$

Express the relationship between the volume V of the first wire and the volume V' of the second wire:

$$V=V' \text{ or } LA=L'A'\Rightarrow\frac{A}{A'}=\frac{L'}{L}=2$$

Substituting for $\frac{A}{A'}$ in equation (1) yields:

$$R'=2(2)R=4R$$

Because R = 3.00 Ω:

$$R'=4(0.300\,\Omega)=\boxed{1.20\,\Omega}$$

46 •• A 10-gauge copper wire can safely carry currents up to 30.0 A. (*a*) What is the resistance of a 100-m length of the wire? (*b*) What is the electric field in the wire when the current is 30.0 A? (*c*) How long does it take for an electron to travel 100 m in the wire when the current is 30.0 A?

Picture the Problem We can use $R=\rho L/A$ to find the resistance of the wire from its length, resistivity, and cross-sectional area. The electric field can be found using $E = V/L$ and Ohm's law to eliminate V. The time for an electron to travel the length of the wire can be found from $L = v_d\Delta t$, with v_d expressed in term of I using $I=neAv_d$.

(*a*) Relate the resistance of the unstretched wire to its resistivity, cross-sectional area, and length:

$$R=\rho\frac{L}{A}$$

Substitute numerical values (see Table 25-1 for the resistivity of copper and Table 25-2 for the cross-sectional area of 10-gauge wire) and evaluate R:

$$R=\left(1.7\times10^{-8}\,\Omega\cdot\text{m}\right)\frac{100\,\text{m}}{5.261\,\text{mm}^2}$$
$$=0.323\,\Omega=\boxed{0.32\,\Omega}$$

(*b*) Relate the electric field in the wire to the potential difference between its ends:

$$E=\frac{V}{L}$$

Use Ohm's law to substitute for V:

$$E=\frac{IR}{L}$$

Substitute numerical values and evaluate E:

$$E = \frac{(30.0\,\text{A})(0.323\,\Omega)}{100\,\text{m}} = \boxed{97\,\text{mV/m}}$$

(c) Express the time Δt for an electron to travel a distance L in the wire in terms of its drift speed v_d:

$$\Delta t = \frac{L}{v_\text{d}}$$

Relate the current in the wire to the drift speed of the charge carriers:

$$I = neAv_\text{d} \Rightarrow v_\text{d} = \frac{I}{neA}$$

Substitute for v_d to obtain:

$$\Delta t = \frac{neAL}{I}$$

Substitute numerical values (in Example 25-1 it is shown that $n = 8.47\times10^{28}\ \text{m}^{-3}$) and evaluate Δt:

$$\Delta t = \frac{(8.47\times10^{28}\ \text{m}^{-3})(1.602\times10^{-19}\ \text{C})(5.261\,\text{mm}^2)(100\,\text{m})}{30.0\,\text{A}}$$

$$= \boxed{2.38\times10^5\ \text{s}} = \boxed{2.75\ \text{d}}$$

47 •• A cube of copper has edges that are 2.00-cm long. If copper in the cube is drawn to form a length of 14-gauge wire, what will the resistance of the length of wire be? Assume the density of the copper does not change.

Picture the Problem We can use $R = \rho L/A$ to find express the resistance of the wire in terms of its length, resistivity, and cross-sectional area. The fact that the volume of the copper does not change as the cube is drawn out to form the wire will allow us to eliminate either the length or the cross-sectional area of the wire and solve for its resistance.

Express the resistance of the wire in terms of its resistivity, cross-sectional area, and length:

$$R = \rho\frac{L}{A}$$

Relate the volume V of the wire to its length and cross-sectional area:

$$V = AL \Rightarrow L = \frac{V}{A}$$

Substitute for L to obtain:

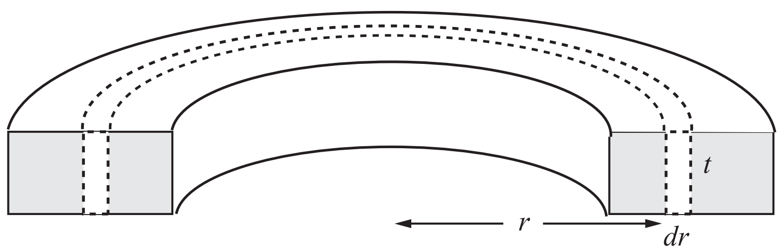
$$R = \rho\frac{V}{A^2}$$

Substitute numerical values (see Table 25-1 for the resistivity of copper and Table 25-2 for the cross-sectional area of 14-gauge wire) and evaluate R:

$$R = \left(1.7\times10^{-8}\ \Omega\cdot\text{m}\right)\frac{\left(2.00\,\text{cm}\right)^3}{\left(2.081\,\text{mm}^2\right)^2} = \boxed{31\,\text{m}\Omega}$$

48 ••• Find an expression for the resistance between the ends of the half ring shown in Figure 25-51. The resistivity of the material constituting the half-ring is ρ. *Hint: Model the half ring as a parallel combination of a large number of thin half-rings. Assume the current is uniformly distributed on a cross section of the half ring.*

Picture the Problem We can use, as our element of resistance, the semicircular strip of height t, radius r, and thickness dr shown below. Then $dR = \left(\pi r\rho/t\right)dr$. Because the strips are in parallel, integrating over them will give us the reciprocal of the resistance of half ring.



The resistance dR between the ends of the infinitesimal strip is given by:

$$dR = \rho\frac{\pi r}{t\,dr}$$

Because the infinitesimal strips are in parallel, their equivalent resistance is:

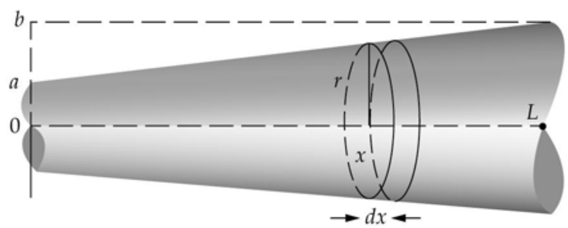
$$\frac{1}{R} = \frac{t}{\pi\rho}\int_a^b \frac{dr}{r}$$

Integrating dR_{eq} from $r = a$ to $r = b$ yields:

$$\frac{1}{R} = \frac{t}{\pi\rho}\ln\left(\frac{b}{a}\right) \Rightarrow R = \boxed{\frac{\rho\pi}{t\ln\left(\frac{b}{a}\right)}}$$

49 ••• **[SSM]** Consider a wire of length L in the shape of a truncated cone. The radius of the wire varies with distance x from the narrow end according to $r = a + [(b - a)/L]x$, where $0 < x < L$. Derive an expression for the resistance of this wire in terms of its length L, radius a, radius b and resistivity ρ. *Hint: Model the wire as a series combination of a large number of thin disks. Assume the current is uniformly distributed on a cross section of the cone.*

Picture the Problem The element of resistance we use is a segment of length dx and cross-sectional area $\pi[a + (b - a)x/L]^2$. Because these resistance elements are in series, integrating over them will yield the resistance of the wire.



Express the resistance of the chosen element of resistance:

$$dR = \rho\frac{dx}{A} = \frac{\rho}{\pi[a+(b-a)(x/L)]^2}dx$$

Integrate dR from $x = 0$ to $x = L$ and simplify to obtain:

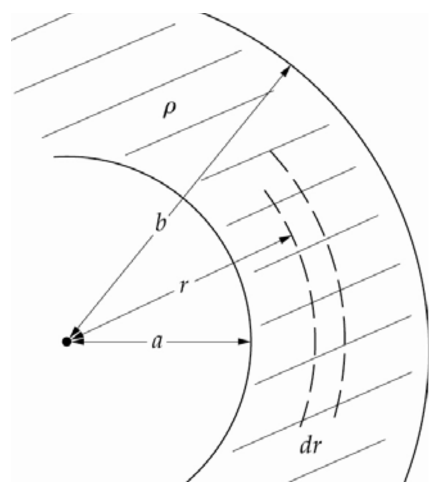
$$R = \frac{\rho}{\pi}\int_0^L \frac{dx}{[a+(b-a)(x/L)]^2}$$

$$= \frac{\rho L}{\pi(b-a)}\left(\frac{1}{a} - \frac{1}{a+(b-a)}\right)$$

$$= \boxed{\frac{\rho L}{\pi ab}}$$

50 ••• The space between two metallic concentric spherical shells is filled with a material that has a resistivity of $3.50 \times 10^{-5}\ \Omega\cdot\text{m}$. If the inner metal shell has an outer radius of 1.50 cm and the outer metal shell has an inner radius of 5.00 cm, what is the resistance between the conductors? *Hint: Model the material as a series combination of a large number of thin spherical shells.*

Picture the Problem The diagram shows a cross-sectional view of the concentric spheres of radii a and b as well as a spherical-shell element of radius r. We can express the resistance dR of the spherical-shell element and then integrate over the volume filled with the material whose resistivity ρ is given to find the resistance between the conductors. Note that the elements of resistance are in series.



Express the element of resistance dR:

$$dR = \rho\frac{dr}{A} = \rho\frac{dr}{4\pi r^2}$$

Integrate dR from $r = a$ to $r = b$ to obtain:

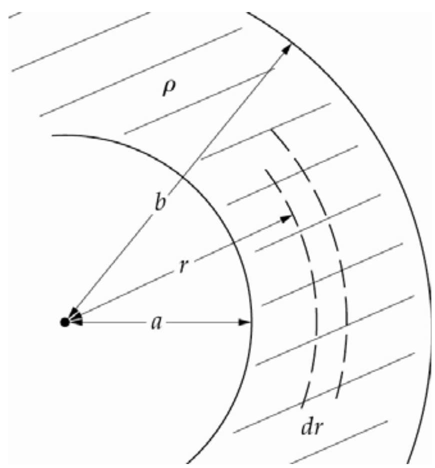
$$R = \frac{\rho}{4\pi}\int_a^b \frac{dr}{r^2} = \frac{\rho}{4\pi}\left(\frac{1}{a} - \frac{1}{b}\right)$$

Substitute numerical values and evaluate R:

$$R = \frac{3.50\times10^{-5}\ \Omega\cdot\text{m}}{4\pi}\left(\frac{1}{1.50\,\text{cm}} - \frac{1}{5.00\,\text{cm}}\right) = \boxed{130\ \mu\Omega}$$

51 ••• The space between two metallic coaxial cylinders that have the same length L is completely filled with a nonmetalic material having a resistivity ρ. The inner metal shell has an outer radius a and the outer metal shell has an inner radius b. (a) What is the resistance between the two cylinders? *Hint: Model the material as a series combination of a large number of thin cylindrical shells.* (b) Find the current between the two metallic cylinders if $\rho = 30.0\ \Omega\text{·m}$, $a = 1.50$ cm, $b = 2.50$ cm, $L = 50.0$ cm, and a potential difference of 10.0 V is maintained between the two cylinders.

Picture the Problem The diagram shows a cross-sectional view of the coaxial cylinders of radii a and b as well as a cylindrical-shell element of radius r. We can express the resistance dR of the cylindrical-shell element and then integrate over the volume filled with the material whose resistivity ρ is given to find the resistance between the two cylinders. Note that the elements of resistance are in series.



(a) Express the element of resistance dR:

$$dR = \rho\frac{dr}{A} = \rho\frac{dr}{2\pi rL}$$

Integrate dR from $r = a$ to $r = b$ to obtain:

$$R = \frac{\rho}{2\pi L}\int_a^b \frac{dr}{r} = \boxed{\frac{\rho}{2\pi L}\ln\left(\frac{b}{a}\right)}$$

(*b*) Apply Ohm's law to obtain:

$$I = \frac{V}{R} = \frac{V}{\frac{\rho}{2\pi L}\ln\left(\frac{b}{a}\right)} = \frac{2\pi LV}{\rho\ln\left(\frac{b}{a}\right)}$$

Substitute numerical values and evaluate I:

$$I = \frac{2\pi(50.0\,\text{cm})(10.0\,\text{V})}{(30.0\,\Omega\cdot\text{m})\ln\left(\frac{2.50\,\text{cm}}{1.50\,\text{cm}}\right)} = \boxed{2.05\,\text{A}}$$

Temperature Dependence of Resistance

52 • A tungsten rod is 50 cm long and has a square cross-section that has 1.0-mm-long edges. (*a*) What is its resistance at 20°C? (*b*) What is its resistance at 40°C?

Picture the Problem We can use $R = \rho L/A$ to find the resistance of the rod at 20°C. Ignoring the effects of thermal expansion, we can we apply the equation defining the temperature coefficient of resistivity, α, to relate the resistance at 40°C to the resistance at 20°C.

(*a*) Express the resistance of the rod at 20°C as a function of its resistivity, length, and cross-sectional area:

$$R_{20} = \rho_{20}\frac{L}{A}$$

Substitute numerical values and evaluate R_{20}:

$$R_{20} = \left(5.5\times10^{-8}\,\Omega\cdot\text{m}\right)\frac{0.50\,\text{m}}{(1.0\,\text{mm})^2}$$
$$= 27.5\,\text{m}\Omega = \boxed{28\,\text{m}\Omega}$$

(*b*) Express the resistance of the rod at 40°C as a function of its resistance at 20°C and the temperature coefficient of resistivity α:

$$R_{40} = \rho_{40}\frac{L}{A}$$
$$= \rho_{20}\left[1+\alpha\left(t_C - 20\text{C}^\circ\right)\right]\frac{L}{A}$$
$$= \rho_{20}\frac{L}{A} + \rho_{20}\frac{L}{A}\alpha\left(t_C - 20\text{C}^\circ\right)$$
$$= R_{20}\left[1+\alpha\left(t_C - 20\text{C}^\circ\right)\right]$$

Substitute numerical values (see Table 25-1 for the temperature coefficient of resistivity of tungsten) and evaluate R_{40}:

$$R_{40} = (27.5\,\text{m}\Omega)\left[1+\left(4.5\times10^{-3}\,\text{K}^{-1}\right)\left(20\,\text{C}^\circ\right)\right] = \boxed{30\,\text{m}\Omega}$$

53 • **[SSM]** At what temperature will the resistance of a copper wire be 10 percent greater than its resistance at 20°C?

Picture the Problem The resistance of the copper wire increases with temperature according to $R_{t_C} = R_{20}\left[1+\alpha\left(t_C - 20\text{C}°\right)\right]$. We can replace R_{t_C} by $1.1R_{20}$ and solve for t_C to find the temperature at which the resistance of the wire will be 110% of its value at 20°C.

Express the resistance of the wire at $1.10R_{20}$:

$$1.10R_{20} = R_{20}\left[1+\alpha\left(t_C - 20\text{C}°\right)\right]$$

Simplifying this expression yields:

$$0.10 = \alpha\left(t_C - 20\text{C}°\right)$$

Solve to t_C to obtain:

$$t_C = \frac{0.10}{\alpha} + 20\text{C}°$$

Substitute numerical values (see Table 25-1 for the temperature coefficient of resistivity of copper) and evaluate t_C:

$$t_C = \frac{0.10}{3.9\times10^{-3}\ \text{K}^{-1}} + 20\text{C}° = \boxed{46°\text{C}}$$

54 •• You have a toaster that uses a Nichrome wire as a heating element. You need to determine the temperature of the Nichrome wire under operating conditions. First, you measure the resistance of the heating element at 20°C and find it to be 80.0 Ω. Then you measure the current immediately after you plug the toaster into a wall outlet—before the temperature of the Nichrome wire increases significantly. You find this startup current to be 8.70 A. When the heating element reaches its operating temperature, you measure the current to be 7.00 A. Use your data to determine the maximum operating temperature of the heating element.

Picture the Problem Let the primed quantities denote the current and resistance at the final temperature of the heating element. We can express R' in terms of R_{20} and the final temperature of the wire t_C using $R' = R_{20}\left[1+\alpha\left(t_C - 20°\text{C}\right)\right]$ and relate I', R', I_{20}, and R_{20} using Ohm's law.

Express the resistance of the heating element at its final temperature as a function of its resistance at 20°C and the temperature coefficient of resistivity for Nichrome:

$$R' = R_{20}\left[1+\alpha\left(t_C - 20°\text{C}\right)\right] \qquad (1)$$

Apply Ohm's law to the heating element when it is first turned on:

$$V = I_{20}R_{20}$$

Apply Ohm's law to the heating element when it has reached its final temperature:

$$V = I'R'$$

Because the voltage is constant, we have:

$$I'R' = I_{20}R_{20} \text{ or } R' = \frac{I_{20}}{I'}R_{20}$$

Substitute in equation (1) to obtain:

$$\frac{I_{20}}{I'}R_{20} = R_{20}\left[1+\alpha\left(t_C - 20°C\right)\right]$$

or

$$\frac{I_{20}}{I'} = 1+\alpha\left(t_C - 20°C\right)$$

Solve for t_C to obtain:

$$t_C = \frac{\frac{I_{20}}{I'} - 1}{\alpha} + 20°C$$

Substitute numerical values (see Table 25-1 for the temperature coefficient of resistivity of Nichrome) and evaluate t_C:

$$t_C = \frac{\frac{8.70\,A}{7.00\,A} - 1}{0.4\times10^{-3}\,K^{-1}} + 20°C \approx \boxed{6\times10^2\,°C}$$

where the answer has only one significant figure because the temperature coefficient is only given to one significant figure.

Remarks: At 600°C the wire glows red.

55 •• Your electric space heater has a Nichrome heating element that has a resistance of 8.00 Ω at 20.0°C. When 120 V are applied, the electric current heats the Nichrome wire to 1000°C. (*a*) What is the initial current in the heating element at 20.0°C? (*b*) What is the resistance of the heating element at 1000°C? (*c*) What is the operating power of this heater?

Picture the Problem We can apply Ohm's law to find the initial current drawn by the cold heating element. The resistance of the wire at 1000°C can be found using $R_{1000} = R_{20}\left[1+\alpha\left(t_C - 20.0°C\right)\right]$ and the power consumption of the heater at this temperature from $P = V^2/R_{1000}$.

(*a*) Apply Ohm's law to find the initial current I_{20} drawn by the heating element:

$$I = \frac{V}{R_{20}} = \frac{120\,\text{V}}{8.00\,\Omega} = \boxed{15.0\,\text{A}}$$

(*b*) Express the resistance of the heating element at 1000°C as a function of its resistance at 20.0°C and the temperature coefficient of resistivity for Nichrome:

$$R_{1000} = R_{20}\left[1 + \alpha\left(t_\text{C} - 20.0°\text{C}\right)\right]$$

Substitute numerical values (see Table 25-1 for the temperature coefficient of resistivity of Nichrome) and evaluate R_{1000}:

$$R_{1000} = (8.00\,\Omega)\left[1 + \left(0.4\times10^{-3}\,\text{K}^{-1}\right)\times\left(1000°\text{C} - 20.0°\text{C}\right)\right] = \boxed{11.1\,\Omega}$$

(*c*) The operating power of this heater at 1000°C is:

$$P = \frac{V^2}{R_{1000}} = \frac{(120\,\text{V})^2}{11.1\,\Omega} = \boxed{1.30\,\text{kW}}$$

56 •• A 10.0-Ω Nichrome resistor is wired into an electronic circuit using copper leads (wires) that have diameters equal to 0.600 mm. The copper leads have a total length of 50.0 cm. (*a*) What additional resistance is due to the copper leads? (*b*) What percentage error in the total resistance is produced by neglecting the resistance of the copper leads? (*c*) What change in temperature would produce a change in resistance of the Nichrome wire equal to the resistance of the copper leads? Assume that the Nichrome section is the only one whose temperature is changed.

Picture the Problem We can find the resistance of the copper leads using $R_\text{Cu} = \rho_\text{Cu} L/A$ and express the percentage error in neglecting the resistance of the leads as the ratio of R_Cu to R_Nichrome. In Part (*c*) we can express the change in resistance in the Nichrome wire corresponding to a change Δt_C in its temperature and then find Δt_C by substitution of the resistance of the copper wires in this equation.

(*a*) Relate the resistance of the copper leads to their resistivity, length, and cross-sectional area:

$$R_\text{Cu} = \rho_\text{Cu}\frac{L}{A}$$

Substitute numerical values (see Table 25-1 for the resistivity of copper) and evaluate R_Cu:

$$R_\text{Cu} = \left(1.7\times10^{-8}\,\Omega\cdot\text{m}\right)\frac{50.0\,\text{cm}}{\frac{1}{4}\pi(0.600\,\text{mm})^2} = 30.1\,\text{m}\Omega = \boxed{30\,\text{m}\Omega}$$

(b) Express the percentage error as the ratio of R_{Cu} to $R_{Nichrome}$:

$$\%\,\text{error} = \frac{R_{Cu}}{R_{Nichrome}} = \frac{30.1\,\text{m}\Omega}{10.0\,\Omega} = \boxed{0.30\%}$$

(c) Express the change in the resistance of the Nichrome wire as its temperature changes from t_C to t_C':

$$\begin{aligned}\Delta R &= R' - R \\ &= R_{20}\left[1+\alpha\left(t_C' - 20°\text{C}\right)\right] \\ &\quad - R_{20}\left[1+\alpha\left(t_C - 20°\text{C}\right)\right] \\ &= R_{20}\alpha\Delta t_C\end{aligned}$$

Solve for Δt_C to obtain:

$$\Delta t_C = \frac{\Delta R}{R_{20}\alpha}$$

Set ΔR equal to the resistance of the copper wires (see Table 25-1 for the temperature coefficient of resistivity of Nichrome wire) and evaluate Δt_C:

$$\Delta t_C = \frac{30.1\,\text{m}\Omega}{(10.0\,\Omega)\left(0.4\times10^{-3}\,\text{K}^{-1}\right)} = \boxed{8°\text{C}}$$

57 ••• [SSM] A wire that has a cross-sectional area A, a length L_1, a resistivity ρ_1, and a temperature coefficient α_1 is connected end to end to a second wire that has the same cross-sectional area, a length L_2, a resistivity ρ_2, and a temperature coefficient α_2, so that the wires carry the same current. (a) Show that if $\rho_1L_1\alpha_1 + \rho_2L_2\alpha_2 = 0$, then the total resistance is independent of temperature for small temperature changes. (b) If one wire is made of carbon and the other wire is made of copper, find the ratio of their lengths for which the total resistance is approximately independent of temperature.

Picture the Problem Expressing the total resistance of the two current-carrying (and hence warming) wires connected in series in terms of their resistivities, temperature coefficients of resistivity, lengths and temperature change will lead us to an expression in which, if $\rho_1L_1\alpha_1 + \rho_2L_2\alpha_2 = 0$, the total resistance is temperature independent. In Part (b) we can apply the condition that

$$\rho_1L_1\alpha_1 + \rho_2L_2\alpha_2 = 0$$

to find the ratio of the lengths of the carbon and copper wires.

(a) Express the total resistance of these two wires connected in series:

$$\begin{aligned}R = R_1 + R_2 &= \rho_1\frac{L_1}{A}\left(1+\alpha_1\Delta T\right) + \rho_2\frac{L_2}{A}\left(1+\alpha_2\Delta T\right) \\ &= \frac{1}{A}\left[\rho_1L_1\left(1+\alpha_1\Delta T\right) + \rho_2L_2\left(1+\alpha_2\Delta T\right)\right]\end{aligned}$$

Expand and simplify this expression to obtain:

$$R = \frac{1}{A}\left[\rho_1 L_1 + \rho_2 L_2 + \left(\rho_1 L_1 \alpha_1 + \rho_1 L_1 \alpha_2\right)\Delta T\right]$$

If $\rho_1 L_1 \alpha_1 + \rho_2 L_2 \alpha_2 = 0$, then:

$R = \boxed{\frac{1}{A}\left[\rho_1 L_1 + \rho_2 L_2\right]}$ independently of the temperature.

(*b*) Apply the condition for temperature independence obtained in (*a*) to the carbon and copper wires:

$$\rho_C L_C \alpha_C + \rho_{Cu} L_{Cu} \alpha_{Cu} = 0$$

Solve for the ratio of L_{Cu} to L_C:

$$\frac{L_{Cu}}{L_C} = -\frac{\rho_C \alpha_C}{\rho_{Cu} \alpha_{Cu}}$$

Substitute numerical values (see Table 25-1 for the temperature coefficient of resistivity of carbon and copper) and evaluate the ratio of L_{Cu} to L_C:

$$\frac{L_{Cu}}{L_C} = -\frac{\left(3500\times10^{-8}\ \Omega\cdot\text{m}\right)\left(-0.5\times10^{-3}\ \text{K}^{-1}\right)}{\left(1.7\times10^{-8}\ \Omega\cdot\text{m}\right)\left(3.9\times10^{-3}\ \text{K}^{-1}\right)} \approx \boxed{3\times10^{2}}$$

58 ••• The resistivity of tungsten increases approximately linearly with temperature from 56.0 nΩ·m at 293 K to 1.10 $\mu\Omega$·m at 3500 K. A light bulb is powered by a a 100-V dc power supply. Under these operating conditions the temperature of the tungsten filament is 2500 K, the length of the filament is equal to 5.00 cm and the power delivered to the filament is 40-W. Estimate (*a*) the resistance of the filament and (*b*) the diameter of the filament.

Picture the Problem We can use the relationship between the rate at which energy is transformed into heat and light in the filament and the resistance of and potential difference across the filament to estimate the resistance of the filament. The linear dependence of the resistivity on temperature will allow us to find the resistivity of the filament at 2500 K. We can then use the relationship between the resistance of the filament, its resistivity, and cross-sectional area to find its diameter.

(*a*) Express the wattage of the lightbulb as a function of its resistance R and the voltage V supplied by the source:

$$P = \frac{V^2}{R} \Rightarrow R = \frac{V^2}{P}$$

Substitute numerical values and evaluate R:

$$R = \frac{(100\,\text{V})^2}{40\,\text{W}} = \boxed{0.25\,\text{k}\Omega}$$

(*b*) Relate the resistance R of the filament to its resistivity ρ, radius r, and length ℓ:

$$R = \frac{\rho\ell}{\pi r^2} \Rightarrow r = \sqrt{\frac{\rho\ell}{\pi R}}$$

The diameter d of the filament is:

$$d = 2\sqrt{\frac{\rho\ell}{\pi R}} \qquad (1)$$

Because the resistivity varies linearly with temperature, we can use a proportion to find its value at 2500 K:

$$\frac{\rho_{2500\,\text{K}} - \rho_{293\,\text{K}}}{\rho_{3500\,\text{K}} - \rho_{293\,\text{K}}} = \frac{2500\,\text{K} - 293\,\text{K}}{3500\,\text{K} - 293\,\text{K}} = \frac{2207}{3207}$$

Solve for $\rho_{2500\,\text{K}}$ to obtain:

$$\rho_{2500\,\text{K}} = \frac{2207}{3207}\left(\rho_{3500\,\text{K}} - \rho_{293\,\text{K}}\right) + \rho_{293\,\text{K}}$$

Substitute numerical values and evaluate $\rho_{2500\,\text{K}}$:

$$\rho_{2500\,\text{K}} = \frac{2207}{3207}\left(1.10\,\mu\Omega\cdot\text{m} - 56.0\,\text{n}\Omega\cdot\text{m}\right) + 56.0\,\text{n}\Omega\cdot\text{m} = 774.5\,\mu\Omega\cdot\text{m}$$

Substitute numerical values in equation (1) and evaluate d:

$$d = 2\sqrt{\frac{(774.5\,\text{n}\Omega\cdot\text{m})(5.00\,\text{cm})}{\pi(250\,\Omega)}} = \boxed{14.0\,\mu\text{m}}$$

59 ••• A 5.00-V light bulb used in an electronics class has a carbon filament that has a length of 3.00 cm and a diameter of 40.0 μm. At temperatures between 500 K and 700 K, the resistivity of the carbon used in making small light bulb filaments is about 3.00×10^{-5} Ω·m. (*a*) Assuming that the bulb is a perfect blackbody radiator, calculate the temperature of the filament under operating conditions. (*b*) One concern about carbon filament bulbs, unlike tungsten filament bulbs, is that the resistivity of carbon decreases with increasing temperature. Explain why this decrease in resistivity is a concern.

Picture the Problem We can use the relationship between the rate at which an object radiates and its temperature to find the temperature of the bulb.

(*a*) At a temperature T, the power emitted by a perfect blackbody is:

$$P = \sigma A T^4$$

where $\sigma = 5.67\times10^{-8}$ W/m^2·K^4 is the Stefan-Boltzmann constant.

Solve for T and substitute for P to obtain:

$$T = \sqrt[4]{\frac{P}{\sigma A}} = \sqrt[4]{\frac{P}{\sigma \pi dL}} = \sqrt[4]{\frac{V^2}{\sigma \pi dLR}}$$

Relate the resistance R of the filament to its resistivity ρ:

$$R = \frac{\rho L}{A} = \frac{4\rho L}{\pi d^2}$$

Substitute for R in the expression for T to obtain:

$$T = \sqrt[4]{\frac{V^2}{\sigma \pi dL \dfrac{4\rho L}{\pi d^2}}} = \sqrt[4]{\frac{V^2 d}{4\sigma L^2 \rho}}$$

Substitute numerical values and evaluate T:

$$T = \sqrt[4]{\frac{(5.00\,\text{V})^2(40.0\times10^{-6}\,\text{m})}{4(5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4)(0.0300\,\text{m})^2(3.00\times10^{-5}\,\Omega\cdot\text{m})}} = \boxed{636\,\text{K}}$$

(b) As the filament heats up, its resistance decreases. This results in more power being dissipated, further heat, higher temperature, etc. If not controlled, this thermal runaway can burn out the filament.

Energy in Electric Circuits

60 • A 1.00-kW heater is designed to operate at 240 V. (a) What is the heater's resistance and what is the current in the wires that supply power to the heater? (b) What is the power delivered to the heater if it operates at 120 V? Assume that its resistance remains the same.

Picture the Problem We can use $P = V^2/R$ to find the resistance of the heater and Ohm's law to find the current it draws.

(a) Express the power output of the heater in terms of its resistance and its operating voltage:

$$P = \frac{V^2}{R} \Rightarrow R = \frac{V^2}{P}$$

Substitute numerical values and evaluate R:

$$R = \frac{(240\,\text{V})^2}{1.00\,\text{kW}} = 57.60\,\Omega = \boxed{57.6\,\Omega}$$

Apply Ohm's law to find the current drawn by the heater:

$$I = \frac{V}{R} = \frac{240\,\text{V}}{57.60\,\Omega} = \boxed{4.17\,\text{A}}$$

(b) The power delivered to the heater operating at 120 V is:

$$P = \frac{(120\,\text{V})^2}{57.60\,\Omega} = \boxed{250\,\text{W}}$$

61 • A battery has an emf of 12 V. How much work does it do in 5.0 s if it delivers a current of 3.0 A?

Picture the Problem We can use the definition of power and the relationship between the battery's power output and its emf to find the work done by it under the given conditions.

Use the definition of power to relate the work done by the battery to the time current is drawn from it:

$$P = \frac{\Delta W}{\Delta t} \Rightarrow \Delta W = P\Delta t$$

Express the power output of the battery as a function of the battery's emf:

$$P = \mathcal{E}I$$

Substituting for P yields:

$$\Delta W = \mathcal{E}I\Delta t$$

Substitute numerical values and evaluate ΔW:

$$\Delta W = (12\,\text{V})(3.0\,\text{A})(5.0\,\text{s}) = \boxed{0.18\,\text{kJ}}$$

62 • An automotive battery has an emf of 12.0 V. When supplying power to the starter motor, the current in the battery is 20.0 A and the terminal voltage of the battery is 11.4 V. What is the internal resistance of the battery?

Picture the Problem We can relate the terminal voltage of the battery to its emf, internal resistance, and the current delivered by it and then solve this relationship for the internal resistance.

Express the terminal potential difference of the battery in terms of its emf and internal resistance:

$$V_a - V_b = \mathcal{E} - Ir \Rightarrow r = \frac{\mathcal{E} - (V_a - V)_b}{I}$$

Substitute numerical values and evaluate r:

$$r = \frac{12.0\,\text{V} - 11.4\,\text{V}}{20.0\,\text{A}} = \boxed{0.03\,\Omega}$$

63 • **[SSM]** (*a*) How much power is delivered by the battery in Problem 62 due to the chemical reactions within the battery when the current in the battery is 20 A? (*b*) How much of this power is delivered to the starter when the current in the battery is 20 A? (*c*) By how much does the chemical energy of the battery decrease if the current in the starter is 20 A for 7.0 s? (*d*) How much energy is dissipated in the battery during these 7.0 seconds?

Picture the Problem We can find the power delivered by the battery from the product of its emf and the current it delivers. The power delivered to the battery can be found from the product of the potential difference across the terminals of the starter (or across the battery when current is being drawn from it) and the current being delivered to it. In Part (*c*) we can use the definition of power to relate the decrease in the chemical energy of the battery to the power it is delivering and the time during which current is drawn from it. In Part (*d*) we can use conservation of energy to relate the energy delivered by the battery to the heat developed in the battery and the energy delivered to the starter

(*a*) Express the power delivered by the battery as a function of its emf and the current it delivers:

$$P = \mathcal{E}I = (12.0\,\text{V})(20\,\text{A}) = 240\,\text{W} = \boxed{0.24\,\text{kW}}$$

(*b*) Relate the power delivered to the starter to the potential difference across its terminals:

$$P_{\text{starter}} = V_{\text{starter}}I = (11.4\,\text{V})(20\,\text{A}) = 228\,\text{W} = \boxed{0.23\,\text{kW}}$$

(*c*) Use the definition of power to express the decrease in the chemical energy of the battery as it delivers current to the starter:

$$\Delta E = P\Delta t = (240\,\text{W})(7.0\,\text{s}) = 1680\,\text{J} = \boxed{1.7\,\text{kJ}}$$

(*d*) Use conservation of energy to relate the energy delivered by the battery to the heat developed in the battery and the energy delivered to the starter:

$$E_{\substack{\text{delivered}\\ \text{by battery}}} = E_{\substack{\text{transformed}\\ \text{into heat}}} + E_{\substack{\text{delivered}\\ \text{to starter}}} = Q + E_{\substack{\text{delivered}\\ \text{to starter}}}$$

Express the energy delivered by the battery and the energy delivered to the starter in terms of the rate at which this energy is delivered:

$$P\Delta t = Q + P_s\Delta t \Rightarrow Q = (P - P_s)\Delta t$$

Substitute numerical values and evaluate Q:

$$Q = (240\,\text{W} - 228\,\text{W})(7.0\,\text{s}) = \boxed{84\,\text{J}}$$

64 • A battery that has an emf of 6.0 V and an internal resistance of 0.30 Ω is connected to a variable resistor with resistance R. Find the current and power delivered by the battery when R is (*a*) 0, (*b*) 5.0 Ω, (*c*) 10 Ω, and (*d*) infinite.

Picture the Problem We can use conservation of energy to relate the emf of the battery to the potential differences across the variable resistor and the energy converted to heat within the battery. Solving this equation for I will allow us to find the current for the four values of R and we can use $P = I^2R$ to find the power delivered by the battery for the four values of R.

Apply conservation of energy (Kirchhoff's loop rule) to the circuit:

$$\mathcal{E} = IR + Ir \Rightarrow I = \frac{\mathcal{E}}{R+r}$$

Express the power delivered by the battery as a function of the current drawn from it:

$$P = I^2R$$

(a) For $R = 0$:

$$I = \frac{\mathcal{E}}{R+r} = \frac{6.0\,\text{V}}{0.30\,\Omega} = \boxed{20\,\text{A}}$$

and

$$P = (20\,\text{A})^2(0) = \boxed{0\,\text{W}}$$

(b) For $R = 5.0\ \Omega$:

$$I = \frac{\mathcal{E}}{R+r} = \frac{6.0\,\text{V}}{5.0\,\Omega + 0.30\,\Omega} = 1.13\,\text{A}$$

$$= \boxed{1.1\,\text{A}}$$

and

$$P = (1.13\,\text{A})^2(5.0\,\Omega) = \boxed{6.4\,\text{W}}$$

(c) For $R = 10\ \Omega$:

$$I = \frac{\mathcal{E}}{R+r} = \frac{6.0\,\text{V}}{10\,\Omega + 0.30\,\Omega} = 0.583\,\text{A}$$

$$= \boxed{0.58\,\text{A}}$$

and

$$P = (0.583\text{A})^2(10\,\Omega) = \boxed{3.4\,\text{W}}$$

(d) For $R = \infty$:

$$I = \frac{\mathcal{E}}{R+r} = \lim_{R\to\infty} \frac{6.0\,\text{V}}{R + 0.30\,\Omega} = \boxed{0\,\text{A}}$$

and

$$P = \boxed{0\,\text{W}}$$

65 •• A 12.0-V automobile battery that has a negligible internal resistance can deliver a total charge of 160 A·h. (*a*) What is the amount of energy stored in the battery? (*b*) After studying all night for a calculus test, you try to drive to class to take the test. However, you find that the car's battery is "dead" because you had left the headlights on! Assuming the battery was able to produce current at a constant rate until it died, how long were your lights on? Assume the pair of headlights together operates at a power of 150 W.

Picture the Problem We can express the total stored energy ΔU in the battery in terms of its emf and the product $I\Delta t$ of the current it can deliver for a period of time Δt. We can apply the definition of power to relate the lifetime of the battery to the rate at which it is providing energy to the pair of headlights.

(*a*) Express ΔU in terms of $\mathcal{E}$ and the product $I\Delta t$:

$$\Delta U = \mathcal{E} I \Delta t$$

Substitute numerical values and evaluate ΔU:

$$\Delta U = (12.0\,\text{V})(160\,\text{A}\cdot\text{h}) = 1.92\,\text{kW}\cdot\text{h}$$
$$= 1.92\,\text{kW}\cdot\text{h} \times \frac{3.6\,\text{MJ}}{\text{kW}\cdot\text{h}}$$
$$= \boxed{6.9\,\text{MJ}}$$

(*b*) Use the definition of power to relate the lifetime of the battery to the rate at which it is providing energy to the pair of headlights:

$$\Delta t = \frac{\Delta U}{P}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{1.92\,\text{kW}\cdot\text{h}}{150\,\text{W}} = \boxed{12.8\,\text{h}}$$

66 •• The measured current in a circuit in your uncle's house is 12.5 A. In this circuit, the only appliance that is on is a space heater that is being used to heat the bathroom. A pair of 12-gauge copper wires carries the current from the supply panel in your basement to the wall outlet in the bathroom, a distance of 30.0 m. You measure the voltage at the supply panel to be exactly 120 V. What is the voltage at the wall outlet in the bathroom that the space heater is connected to?

Picture the Problem We can use conservation of energy (Kirchhoff's loop rule) to relate the emf at the fuse box and the voltage drop in the wires to the voltage at the wall outlet in the bathroom.

Apply Kirchhoff's loop rule to the circuit to obtain:

$$\mathcal{E} - V_{\text{wires}} - V_{\text{outlet}} = 0$$

or

$$\mathcal{E} - IR_{\text{wires}} - V_{\text{outlet}} = 0$$

Solve for V_{outlet} to obtain:

$$V_{\text{outlet}} = \mathcal{E} - IR_{\text{wires}}$$

Relate the resistance of the copper wires to the resistivity of copper, the length of the wires, and the cross-sectional area of 12-gauge wire:

$$R_{\text{wires}} = \rho_{\text{Cu}} \frac{L}{A}$$

Substituting for R_{wires} yields:

$$V_{\text{outlet}} = \mathcal{E} - \frac{I\rho_{\text{Cu}}L}{A}$$

Substitute numerical values (see Table 25 -1 for the resistivity of copper and Table 25-2 for the cross-sectional area of 12-gauge wire) and evaluate V_{outlet}:

$$V_{\text{outlet}} = 120\,\text{V} - \frac{(12.5\,\text{A})(1.7\times10^{-8}\,\Omega\cdot\text{m})(60.0\,\text{m})}{3.309\,\text{mm}^2} = \boxed{116\,\text{V}}$$

67 •• [SSM] A lightweight electric car is powered by a series combination of ten 12.0-V batteries, each having negligible internal resistance. Each battery can deliver a charge of 160 A·h before needing to be recharged. At a speed of 80.0 km/h, the average force due to air drag and rolling friction is 1.20 kN. (*a*) What must be the minimum power delivered by the electric motor if the car is to travel at a speed of 80.0 km/h? (*b*) What is the total charge, in coulombs, that can be delivered by the series combination of ten batteries before recharging is required? (*c*) What is the total electrical energy delivered by the ten batteries before recharging? (*d*) How far can the car travel (at 80.0 km/h) before the batteries must be recharged? (*e*) What is the cost per kilometer if the cost of recharging the batteries is 9.00 cents per kilowatt-hour?

Picture the Problem We can use $P = fv$ to find the power the electric motor must develop to move the car at 80 km/h against a frictional force of 1200 N. We can find the total charge that can be delivered by the 10 batteries using $\Delta Q = NI\Delta t$. The total electrical energy delivered by the 10 batteries before recharging can be found using the definition of emf. We can find the distance the car can travel from the definition of work and the cost per kilometer of driving the car this distance by dividing the cost of the required energy by the distance the car has traveled.

(*a*) Express the power the electric motor must develop in terms of the speed of the car and the friction force:

$$P = fv = (1.20\,\text{kN})(80.0\,\text{km/h}) = \boxed{26.7\,\text{kW}}$$

(*b*) Because the batteries are in series, the total charge that can be delivered before charging is the same as the charge from a single battery:

$$\Delta Q = I\Delta t = (160\,\text{A}\cdot\text{h})\left(\frac{3600\,\text{s}}{\text{h}}\right) = \boxed{576\,\text{kC}}$$

(*c*) Use the definition of emf to express the total electrical energy available in the batteries:

$$W = Q\mathcal{E} = 10(576\,\text{kC})(12.0\,\text{V}) = 69.12\,\text{MJ} = \boxed{69.1\,\text{MJ}}$$

(*d*) Relate the amount of work the batteries can do to the work required to overcome friction:

$$W = fd \Rightarrow d = \frac{W}{f}$$

Substitute numerical values and evaluate *d*:

$$d = \frac{69.12\,\text{MJ}}{1.20\,\text{kN}} = \boxed{57.6\,\text{km}}$$

(*e*) The cost per kilometer is the ratio of the cost of the energy to the distance traveled before recharging:

$$\text{Cost/km} = \frac{\left(\dfrac{\$0.0900}{\text{kW}\cdot\text{h}}\right)\mathcal{E}\,I\,t}{d}$$

Substitute numerical values and calculate the cost per kilometer:

$$\text{Cost/km} = \frac{\left(\dfrac{\$0.0900}{\text{kW}\cdot\text{h}}\right)(120\,\text{V})(160\,\text{A}\cdot\text{h})}{5.76\,\text{km}} = \boxed{\$0.300/\text{km}}$$

68 ••• A 100-W heater is designed to operate with an applied voltage of 120 V. (*a*) What is the heater's resistance, and what current does the heater carry? (*b*) Show that if the potential difference V across the heater changes by a small amount ΔV, the power P changes by a small amount ΔP, where $\Delta P/P \approx 2\Delta V/V$. *Hint*: *Approximate the changes by modeling them as differentials, and assume the resistance is constant.* (*c*) Using the Part-(*b*) result, find the approximate power dissipated in the heater, if the potential difference is decreased to 115 V. Compare your result to the exact answer.

Picture the Problem We can use the definition of power to find the current drawn by the heater and Ohm's law to find its resistance. In Part (*b*) we'll use the hint to show that $\Delta P/P \approx 2\Delta V/V$ and in Part (*c*) use this result to find the approximate power dissipated in the heater if the potential difference is decreased to 115 V.

(*a*) Use the definition of power to relate the current I drawn by the heater to its power rating P and the potential difference across it V:

$$P = IV \Rightarrow I = \frac{P}{V}$$

Substitute numerical values and evaluate I:

$$I = \frac{100\text{ W}}{120\text{ V}} = \boxed{0.833\text{ A}}$$

Apply Ohm's law to relate the resistance of the heater to the voltage across it and the current it draws:

$$R = \frac{V}{I} = \frac{120\text{ V}}{0.833\text{ A}} = \boxed{144\,\Omega}$$

(*b*) Approximating dP/dV as a differential yields:

$$\frac{dP}{dV} \approx \frac{\Delta P}{\Delta V} \Rightarrow \Delta P \approx \frac{dP}{dV}\Delta V$$

Express the dependence of P on V:

$$P = \frac{V^2}{R}$$

Assuming R to be constant, evaluate dP/dV:

$$\frac{dP}{dV} = \frac{d}{dV}\left[\frac{V^2}{R}\right] = \frac{2V}{R}$$

Substitute to obtain:

$$\Delta P \approx \frac{2V}{R}\Delta V = 2\frac{V^2}{R}\frac{\Delta V}{V} = 2P\frac{\Delta V}{V}$$

Divide both sides of the equation by P to obtain:

$$\frac{\Delta P}{P} = \boxed{2\frac{\Delta V}{V}}$$

(*c*) Express the approximate power dissipated in the heater as the sum of its power consumption and the change in its power dissipation when the voltage is decreased by ΔV:

$$\begin{aligned} P &\approx P_0 + \Delta P \\ &= P_0 + 2P_0\frac{\Delta V}{V} \qquad (1) \\ &= P_0\left(1 + 2\frac{\Delta V}{V}\right) \end{aligned}$$

Assuming that the difference between 120 V and 115 V is good to three significant figures, substitute numerical values and evaluate P:

$$P \approx (100\,\text{W})\left(1 + 2\left(\frac{-5.00\,\text{V}}{120\,\text{V}}\right)\right) = \boxed{91.7\text{ W}}$$

The exact power dissipated in the heater is:

$$P_{\text{exact}} = \frac{V'^2}{R} = \frac{(115\,\text{V})^2}{144\,\Omega} = 91.8\text{ W}$$

The power calculated using the approximation is 0.1 percent less than the power calculated exactly.

Combinations of Resistors

69 • **[SSM]** If the potential drop from point *a* to point *b* (Figure 25-52) is 12.0 V, find the current in each resistor.

Picture the Problem We can apply Ohm's law to find the current through each resistor.

Apply Ohm's law to each of the resistors to find the current flowing through each:

$$I_4 = \frac{V}{4.00\,\Omega} = \frac{12.0\,\text{V}}{4.00\,\Omega} = \boxed{3.00\,\text{A}}$$

$$I_3 = \frac{V}{3.00\,\Omega} = \frac{12.0\,\text{V}}{3.00\,\Omega} = \boxed{4.00\,\text{A}}$$

and

$$I_6 = \frac{V}{6.00\,\Omega} = \frac{12.0\,\text{V}}{6.00\,\Omega} = \boxed{2.00\,\text{A}}$$

Remarks: You would find it instructive to use Kirchhoff's junction rule (conservation of charge) to confirm our values for the currents through the three resistors.

70 • If the potential drop between point *a* and point *b* (Figure 25-53) is 12.0 V, find the current in each resistor.

Picture the Problem We can simplify the network by first replacing the resistors that are in parallel by their equivalent resistance. We can then add that resistance and the 3.00-Ω resistance to find the equivalent resistance between points *a* and *b*. Denoting the currents through each resistor with subscripts corresponding to the resistance through which the current flows, we can apply Ohm's law to find those currents.

Express the equivalent resistance of the two resistors in parallel and solve for $R_{\text{eq},1}$:

$$\frac{1}{R_{\text{eq},1}}=\frac{1}{R_6}+\frac{1}{R_2}=\frac{1}{6.00\,\Omega}+\frac{1}{2.00\,\Omega}$$

and

$$R_{\text{eq},1}=1.50\,\Omega$$

Because the 3.00-Ω resistor is in series with $R_{\text{eq},1}$:

$$R_{\text{eq}}=R_3+R_{\text{eq},1}=3.00\,\Omega+1.50\,\Omega=4.50\,\Omega$$

Apply Ohm's law to the network to find I_3:

$$I_3=\frac{V_{ab}}{R_{\text{eq}}}=\frac{12.0\,\text{V}}{4.50\,\Omega}=2.667\text{ A}=\boxed{2.67\,\text{A}}$$

Find the potential difference across the parallel resistors:

$$V_{6\,\&\,2}=V_{ab}-V_3=12.0\,\text{V}-(2.667\,\text{A})(3.00\,\Omega)=3.999\,\text{V}$$

Use the common potential difference across the resistors in parallel to find the current through each of them:

$$I_6=\frac{V_6}{R_6}=\frac{3.999\,\text{V}}{6.00\Omega}=\boxed{0.667\,\text{A}}$$

and

$$I_2=\frac{V_{6\&2}}{R_2}=\frac{3.999\,\text{V}}{2.00\Omega}=\boxed{2.00\,\text{A}}$$

Remarks: We could have found the currents through the 6.00-Ω and 2.00-Ω resistors by using the fact that the current at the junction between the 3.00-Ω resistor and the parallel branch divides inversely with the resistance in each branch of the parallel network.

71 • (*a*) Show that the equivalent resistance between point *a* and point *b* in Figure 25-54 is *R*. (*b*) How would adding a fifth resistor that has resistance *R* between point *c* and point *d* effect the equivalent resistance between point *a* and point *b*?

Picture the Problem Note that the resistors between *a* and *c* and between *c* and *b* are in series as are the resistors between *a* and *d* and between *d* and *b*. Hence, we have two branches in parallel, each branch consisting of two resistors *R* in series. In Part (*b*) it will be important to note that the potential difference between point *c* and point *d* is zero.

(*a*) Express the equivalent resistance between points *a* and *b* in terms of the equivalent resistances between *acb* and *adb*:

$$\frac{1}{R_{\text{eq}}}=\frac{1}{R_{acb}}+\frac{1}{R_{adb}}=\frac{1}{2R}+\frac{1}{2R}$$

Solve for R_{eq} to obtain:

$$R_{\text{eq}}=\boxed{R}$$

(*b*) It would not affect it. Because the potential difference between points c and d is zero, no current would flow through the resistor connected between these two points, and the addition of that resistor would not change the network.

72 •• The battery in Figure 25-55 has negligible internal resistance. Find (*a*) the current in each resistor and (*b*) the power delivered by the battery.

Picture the Problem Note that the 2.00-Ω resistors are in parallel with each other and with the 4.00-Ω resistor. We can Apply Kirchhoff's loop rule to relate the current I_3 drawn from the battery to the emf of the battery and equivalent resistance R_{eq} of the resistor network. We can find the current through the resistors connected in parallel by applying Kirchhoff's loop rule a second time. In Part (*b*) we can find the power delivered by the battery from the product of its emf and the current it delivers to the circuit.

(*a*) Apply Kirchhoff's loop rule to obtain:

$$\mathcal{E}-I_3R_{\text{eq}}=0\Rightarrow I_3=\frac{\mathcal{E}}{R_{\text{eq}}}\qquad(1)$$

Find the equivalent resistance of the three resistors in parallel:

$$\frac{1}{R_{\text{eq},1}}=\frac{1}{R_2}+\frac{1}{R_2}+\frac{1}{R_4}=\frac{1}{2.00\,\Omega}+\frac{1}{2.00\,\Omega}+\frac{1}{4.00\,\Omega}$$

and

$$R_{\text{eq},1}=0.800\,\Omega$$

Find the equivalent resistance of $R_{\text{eq},1}$ and R_3 in series:

$$R_{\text{eq}}=R_3+R_{\text{eq},1}=3.00\,\Omega+0.800\,\Omega=3.80\,\Omega$$

Substitute numerical values in equation (1) and evaluate I_3:

$$I_3=\frac{6.00\,\text{V}}{3.80\,\Omega}=1.579\text{ V}=\boxed{1.58\,\text{A}}$$

Express the current through each of the parallel resistors in terms of their common potential difference V:

$$I_2=\frac{V}{R_2}\text{ and }I_4=\frac{V}{R_4}$$

Apply Kirchhoff's loop rule to obtain:

$$\mathcal{E} - I_3R_3 - V = 0 \Rightarrow V = \mathcal{E} - I_3R_3$$

Substituting for V in the equations for I_2 and I_4 yields:

$$I_2 = \frac{\mathcal{E} - I_3R_3}{R_2} \text{ and } I_4 = \frac{\mathcal{E} - I_3R_3}{R_4}$$

Substitute numerical values and evaluate I_2 and I_4:

$$I_2 = \frac{6.00\,\text{V} - (1.579\,\text{A})(3.00\,\Omega)}{2.00\,\Omega}$$

$$= \boxed{0.632\,\text{A}}$$

and

$$I_4 = \frac{6.00\,\text{V} - (1.579\,\text{A})(3.00\,\Omega)}{4.00\,\Omega}$$

$$= \boxed{0.316\,\text{A}}$$

(b) P is the product of $\mathcal{E}$ and I_3:

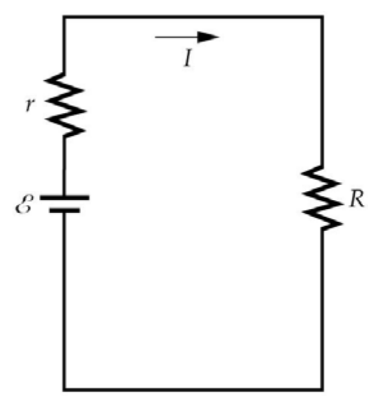
$$P = \mathcal{E}I_3 = (6.00\,\text{V})(1.579\,\text{A})$$

$$= \boxed{9.47\,\text{W}}$$

Remarks: Note that the currents I_3, I_2, and I_4 satisfy Kirchhoff's junction rule.

73 •• [SSM] A 5.00-V power supply has an internal resistance of 50.0 Ω. What is the smallest resistor that can be put in series with the power supply so that the voltage drop across the resistor is larger than 4.50 V?

Picture the Problem Let r represent the resistance of the internal resistance of the power supply, $\mathcal{E}$ the emf of the power supply, R the resistance of the external resistor to be placed in series with the power supply, and I the current drawn from the power supply. We can use Ohm's law to express the potential difference across R and apply Kirchhoff's loop rule to express the current through R in terms of $\mathcal{E}$, r, and R.



Express the potential difference across the resistor whose resistance is R:

$$V_R = IR \qquad (1)$$

Apply Kirchhoff's loop rule to the circuit to obtain:

$$\mathcal{E} - Ir - IR = 0 \Rightarrow I = \frac{\mathcal{E}}{r+R}$$

Substitute in equation (1) to obtain:

$$V_R = \left(\frac{\mathcal{E}}{r+R}\right)R \Rightarrow R = \frac{V_R r}{\mathcal{E} - V_R}$$

Substitute numerical values and evaluate R:

$$R = \frac{(4.50\,\text{V})(50.0\,\Omega)}{5.00\,\text{V} - 4.50\,\text{V}} = \boxed{0.45\,\text{k}\Omega}$$

74 •• You have been handed an unknown battery. Using your multimeter, you determine that when a 5.00-Ω resistor is connected across the battery's terminals, the current in the battery is 0.500 A. When this resistor is replaced by an 11.0-Ω resistor, the current drops to 0.250 A. From this data, find (*a*) the emf and (*b*) internal resistance of your battery.

Picture the Problem We can apply Kirchhoff's loop rule to the two circuits described in the problem statement and solve the resulting equations simultaneously for r and $\mathcal{E}$.

(*a*) and (*b*) Apply Kirchhoff's loop rule to the two circuits to obtain:

$$\mathcal{E} - I_1 r - I_1 R_5 = 0$$

and

$$\mathcal{E} - I_2 r - I_2 R_{11} = 0$$

Substitute numerical values and simplify to obtain:

$$\mathcal{E} - (0.500\,\text{A})r = 2.50\,\text{V} \qquad (1)$$

and

$$\mathcal{E} - (0.250\,\text{A})r = 2.75\,\text{V} \qquad (2)$$

Solve equations (1) and (2) simultaneously to obtain:

$$\mathcal{E} = \boxed{3.00\,\text{V}} \text{ and } r = \boxed{1.00\,\Omega}$$

75 •• (*a*) Find the equivalent resistance between point *a* and point *b* in Figure 25-56. (*b*) If the potential drop between point *a* and point *b* is 12.0 V, find the current in each resistor.

Picture the Problem We can simplify the network by first replacing the resistors that are in parallel by their equivalent resistance. We'll then have a parallel network with two resistors in series in each branch and can use the expressions for resistors in series to simplify the network to two resistors in parallel. The equivalent resistance between points *a* and *b* will be the single resistor equivalent to these two resistors. In Part (*b*) we'll use the fact that the potential difference across the upper branch is the same as the potential difference across the lower branch, in conjunction with Ohm's law, to find the currents through each resistor.

(*a*) The equivalent resistance of the two 6.00-Ω resistors in parallel is given by:

$$R_{\text{eq},1} = \frac{R_6 R_6}{R_6 + R_6} = \frac{(6.00\,\Omega)^2}{6.00\,\Omega + 6.00\,\Omega} = 3.00\,\Omega$$

Find the equivalent resistance of the 6.00-Ω resistor is in series with $R_{\text{eq},1}$:

$$R_{\text{eq},2} = R_6 + R_{\text{eq},1} = 6.00\,\Omega + 3.00\,\Omega = 9.00\,\Omega$$

Find the equivalent resistance of the 12.0-Ω resistor in series with the 6.00-Ω resistor:

$$R_{\text{eq},3} = R_6 + R_{12} = 6.00\,\Omega + 12.0\,\Omega = 18.0\,\Omega$$

Finally, find the equivalent resistance of $R_{\text{eq},3}$ in parallel with $R_{\text{eq},2}$:

$$R_{\text{eq}} = \frac{R_{\text{eq},2} R_{\text{eq},3}}{R_{\text{eq},2} + R_{\text{eq},3}} = \frac{(9.00\,\Omega)(18.0\,\Omega)}{9.00\,\Omega + 18.0\,\Omega} = \boxed{6.00\,\Omega}$$

(*b*) Apply Ohm's law to the upper branch to find the current $I_{\substack{\text{upper}\\\text{branch}}} = I_{12} = I_6$:

$$I_{\substack{\text{upper}\\\text{branch}}} = I_{12} = I_6 = \frac{V_{ab}}{R_{\text{eq},3}} = \frac{12.0\text{ V}}{18.0\,\Omega} = \boxed{667\text{ mA}}$$

Apply Ohm's law to the lower branch to find the current $I_{\substack{\text{lower}\\\text{branch}}} = I_{\substack{6.00\text{-}\Omega\text{ resistor}\\\text{in series}}}$:

$$I_{\substack{\text{lower}\\\text{branch}}} = I_{\substack{6.00\text{-}\Omega\text{ resistor}\\\text{in series}}} = \frac{V_{ab}}{R_{\text{eq},2}} = \frac{12.0\text{ V}}{9.00\,\Omega} = \boxed{1.33\text{ A}}$$

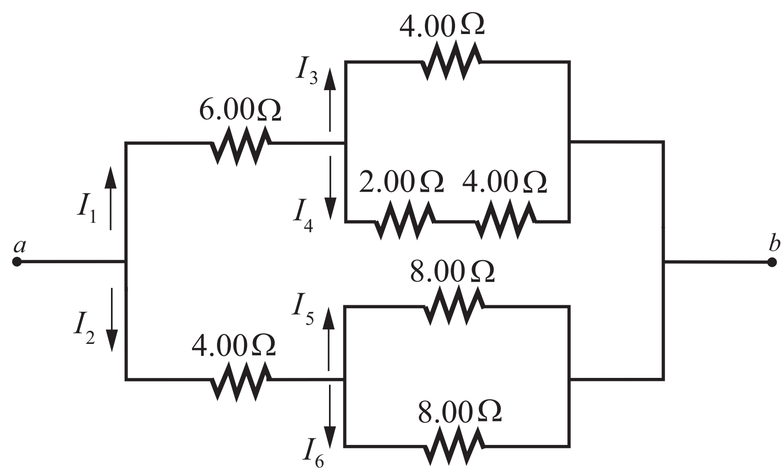
Express the current through the 6.00-Ω resistors in parallel:

$$I_{\substack{6.00\text{-}\Omega\text{ resistors}\\\text{in parallel}}} = \tfrac{1}{2} I_l = \tfrac{1}{2}(1.33\text{ A}) = \boxed{667\text{ mA}}$$

In summary, the current in both the 6.00-Ω and the 12.0-Ω resistor in the upper branch is 667 mA. The current in each 6.00-Ω resistor in the parallel combination in the lower branch is 667 mA. The current in the 6.00-Ω resistor on the right in the lower branch is 1.33 A.

76 •• (*a*) Find the equivalent resistance between point *a* and point *b* in Figure 25-57. (*b*) If the potential drop between point *a* and point *b* is 12.0 V, find the current in each resistor.

Picture the Problem Assign currents in each of the resistors as shown in the diagram. We can simplify the network by first replacing the resistors that are in parallel by their equivalent resistance. We'll then have a parallel network with two resistors in series in each branch and can use the expressions for resistors in series to simplify the network to two resistors in parallel. The equivalent resistance between points *a* and *b* will be the single resistor equivalent to these two resistors. In Part (*b*) we'll use the fact that the potential difference across the upper branch is the same as the potential difference across the lower branch, in conjunction with Ohm's law, to find the currents through each resistor.



(*a*) Find the equivalent resistance of the resistors in parallel in the upper branch:

$$R_{\text{eq},1} = \frac{(R_2 + R_4)R_4}{(R_2 + R_4) + R_4}$$
$$= \frac{(6.00\,\Omega)(4.00\,\Omega)}{2.00\,\Omega + 4.00\,\Omega + 4.00\,\Omega}$$
$$= 2.40\,\Omega$$

Find the equivalent resistance of the 6.00-Ω resistor is in series with $R_{\text{eq},1}$:

$$R_{\text{eq},2} = R_6 + R_{\text{eq},1}$$
$$= 6.00\,\Omega + 2.40\,\Omega = 8.40\,\Omega$$

Express and evaluate the equivalent resistance of the resistors in parallel in the lower branch and solve for $R_{\text{eq},2}$:

$$R_{\text{eq},2} = \frac{R_8 R_8}{R_8 + R_8} = \tfrac{1}{2}R_8 = 4.00\Omega$$

Find the equivalent resistance of the 4.00-Ω resistor is in series with $R_{\text{eq},2}$:

$$R_{\text{eq},3} = R_4 + R_{\text{eq},2}$$
$$= 4.00\,\Omega + 4.00\,\Omega = 8.00\,\Omega$$

Finally, find the equivalent resistance of $R_{\text{eq},2}$ in parallel with $R_{\text{eq},3}$:

$$R_{\text{eq}}=\frac{R_{\text{eq},2}R_{\text{eq},3}}{R_{\text{eq},2}+R_{\text{eq},3}}=\frac{(8.40\,\Omega)(8.00\,\Omega)}{8.40\,\Omega+8.00\,\Omega}=\boxed{4.10\,\Omega}$$

(*b*) Apply Ohm's law to the upper branch to find the current I_1 through the 6.00-Ω resistor:

$$I_1=\frac{V_{ab}}{R_{\text{eq},2}}=\frac{12.0\,\text{V}}{8.40\,\Omega}=\boxed{1.43\,\text{A}}$$

Find the potential difference across the 4.00-Ω and 6.00-Ω parallel combination in the upper branch:

$$\begin{aligned}V_{4\text{ and }6}&=12.0\,\text{V}-V_6=12.0\,\text{V}-I_1R_6\\&=12.0\,\text{V}-(1.43\,\text{A})(6.00\,\Omega)\\&=3.43\,\text{V}\end{aligned}$$

Apply Ohm's law to find I_4:

$$I_4=\frac{V_6}{R_6}=\frac{3.43\,\text{V}}{6.00\,\Omega}=\boxed{0.57\,\text{A}}$$

Apply Ohm's law to find I_3:

$$I_3=\frac{V_4}{R_4}=\frac{3.43\,\text{V}}{4.00\,\Omega}=\boxed{0.86\,\text{A}}$$

Apply Ohm's law to the lower branch to find I_2:

$$I_2=\frac{V_{ab}}{R_{\text{eq},2}}=\frac{12.0\,\text{V}}{8.00\,\Omega}=\boxed{1.50\,\text{A}}$$

Find the potential difference across the 8.00-Ω and 8.00-Ω parallel combination in the lower branch:

$$\begin{aligned}V_{8\text{ and }8}&=12.0\,\text{V}-I_2R_4\\&=12.0\,\text{V}-(1.50\,\text{A})(4.00\,\Omega)\\&=6.0\,\text{V}\end{aligned}$$

Apply Ohm's law to find $I_5=I_6$:

$$I_5=I_6=\frac{V_{8\text{ and }8}}{8.00\,\Omega}=\frac{6.0\,\text{V}}{8.00\,\Omega}=\boxed{0.75\,\text{A}}$$

In summary, the current through the 6.00-Ω resistor is 1.43 A, the current through the lower 4.00-Ω resistor is 1.50 A, the current through the 4.00-Ω resistor that is in parallel with the 2.00-Ω and 4.00-Ω resistors is 0.86 A, the current through the 2.00-Ω and 4.00-Ω resistors that are in series is 0.57 A, and the currents through the two 8.00-Ω resistors are 0.75 A.

77 •• [SSM] A length of wire has a resistance of 120 Ω. The wire is cut into pieces that have the same length, and then the wires are connected in parallel. The resistance of the parallel arrangement is 1.88 Ω. Find the number of pieces into which the wire was cut.

Picture the Problem We can use the equation for N identical resistors connected in parallel to relate N to the resistance R of each piece of wire and the equivalent resistance R_{eq}.

Express the resistance of the N pieces connected in parallel:

$$\frac{1}{R_{eq}} = \frac{N}{R}$$

where R is the resistance of one of the N pieces.

Relate the resistance of one of the N pieces to the resistance of the wire:

$$R = \frac{R_{wire}}{N}$$

Substitute for R to obtain:

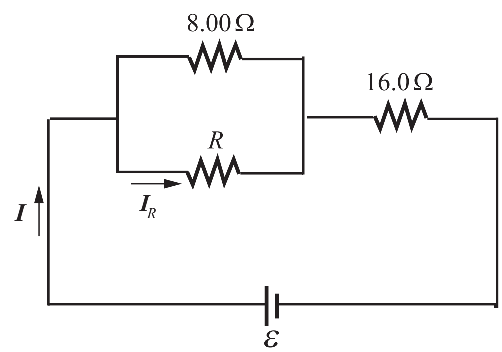
$$\frac{1}{R_{eq}} = \frac{N^2}{R_{wire}} \Rightarrow N = \sqrt{\frac{R_{wire}}{R_{eq}}}$$

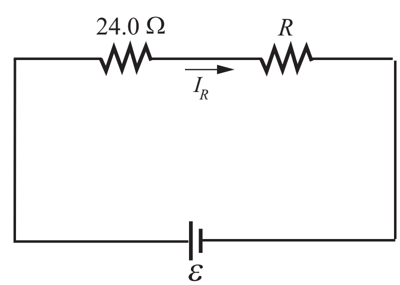
Substitute numerical values and evaluate N:

$$N = \sqrt{\frac{120\,\Omega}{1.88\,\Omega}} = \boxed{8 \text{ pieces}}$$

78 •• A parallel combination of an 8.00-Ω resistor and a resistor of unknown resistance is connected in series with a 16.0-Ω resistor and an ideal battery. This circuit is then disassembled and the three resistors are then connected in series with each other and the same battery. In both arrangements, the current through the 8.00-Ω resistor is the same. What is the resistance of the unknown resistor?

Picture the Problem The same current I_R flows in R when the resistors are connected as shown in the following diagrams. Applying Kirchhoff's loop rule to these circuits will yield expressions for I_R that we can solve simultaneously for R.





Applying Kirchhoff's loop rule to the circuit to the left gives:

$$\varepsilon - I(16.0\,\Omega) - \frac{(8.00\,\Omega)R}{8.00\,\Omega + R} = 0$$

Solve for I to obtain:

$$I=\frac{\varepsilon}{16.0\,\Omega+\dfrac{(8.00\,\Omega)R}{8.00\,\Omega+R}}$$

Applying Kirchhoff's loop rule to the loop that includes the source, the 16.0-Ω resistor and R yields:

$$\varepsilon-I(16.0\,\Omega)-I_R R=0$$

Solve for I_R to obtain:

$$I_R=\frac{\varepsilon-I(16.0\,\Omega)}{R}$$

Substituting for I and simplifying gives:

$$I_R=\frac{\varepsilon-\dfrac{\varepsilon}{16.0\,\Omega+\dfrac{(8.00\,\Omega)R}{8.00\,\Omega+R}}(16.0\,\Omega)}{R}$$

$$=\frac{\varepsilon}{R}-\frac{\varepsilon}{R}\left(\frac{1}{1+\dfrac{R}{16.0\,\Omega+2R}}\right)$$

Apply Kirchhoff's loop rule to the circuit to the right to obtain:

$$\varepsilon-I_R(24.0\,\Omega)-I_R R=0$$

Solving for I_R gives:

$$I_R=\frac{\varepsilon}{24.0\,\Omega+R}$$

Equating the two expressions for I_R yields:

$$\frac{\varepsilon}{R}-\frac{\varepsilon}{R}\left(\frac{1}{1+\dfrac{R}{16.0\,\Omega+2R}}\right)=\frac{\varepsilon}{24.0\,\Omega+R}$$

Simplify to obtain:

$$\frac{\varepsilon}{R}-\frac{\varepsilon}{R}\left(\frac{1}{1+\dfrac{R}{16.0\,\Omega+2R}}\right)=\frac{\dfrac{\varepsilon}{R}}{\dfrac{24.0\,\Omega}{R}+1}$$

or

$$1-\frac{1}{1+\dfrac{R}{16.0\,\Omega+2R}}=\frac{1}{\dfrac{24.0\,\Omega}{R}+1}$$

Solving for R yields:

$$R=\boxed{4.00\,\Omega}$$

79 •• For the network shown in Figure 25-58, let R_{ab} denote the equivalent resistance between terminals *a* and *b*. Find (*a*) R_3, so that $R_{ab} = R_1$, (*b*) R_2, so that $R_{ab} = R_3$; and (*c*) R_1, so that $R_{ab} = R_1$.

Picture the Problem We can find the equivalent resistance R_{ab} between points *a* and *b* and then set this resistance equal, in turn, to R_1, R_3, and R_1 and solve for R_3, R_2, and R_1, respectively.

(*a*) Express the equivalent resistance between points *a* and *b*:

$$R_{ab} = \frac{R_1 R_2}{R_1 + R_2} + R_3$$

Equate this expression to R_1 and solve for R_3 to obtain:

$$R_1 = \frac{R_1 R_2}{R_1 + R_2} + R_3 \Rightarrow R_3 = \boxed{\frac{R_1^2}{R_1 + R_2}}$$

(*b*) Set R_3 equal to R_{ab}:

$$R_3 = \frac{R_1 R_2}{R_1 + R_2} + R_3$$

Solve for R_2 to obtain:

$$R_2 = \boxed{0}$$

(*c*) Set R_1 equal to R_{ab} and rewrite the result as a quadratic equation in R_1:

$$R_1 = \frac{R_1 R_2}{R_1 + R_2} + R_3$$

or

$$R_1^2 - R_3 R_1 - R_2 R_3 = 0$$

Solving the quadratic equation for R_1 yields:

$$R_1 = \boxed{\frac{R_3 + \sqrt{R_3^2 + 4R_2 R_3}}{2}}$$

where we've used the positive sign because resistance is a non-negative quantity.

80 •• Check your results for Problem 79 using the following specific values: (*a*) $R_1 = 4.00\ \Omega$, $R_2 = 6.00\ \Omega$; (*b*) $R_1 = 4.00\ \Omega$, $R_3 = 3.00\ \Omega$; and (*c*) $R_2 = 6.00\ \Omega$, $R_3 = 3.00\ \Omega$.

Picture the Problem We can substitute the given resistances in the equations derived in Problem 79.

(a) For $R_1 = 4.00\ \Omega$ and $R_2 = 6.00\ \Omega$:

$$R_3 = \frac{R_1^2}{R_1 + R_2} = \frac{(4.00\,\Omega)^2}{4.00\,\Omega + 6.00\,\Omega} = \boxed{1.60\,\Omega}$$

and

$$R_{ab} = \frac{R_1 R_2}{R_1 + R_2} + R_3 = \frac{(4.00\,\Omega)(6.00\,\Omega)}{4.00\,\Omega + 6.00\,\Omega} + 1.60\,\Omega = \boxed{4.00\,\Omega}$$

(b) For $R_1 = 4.00\ \Omega$ and $R_3 = 3.00\ \Omega$:

$$R_2 = \boxed{0}$$

and

$$R_{ab} = \frac{R_1(0)}{R_1 + 0} + R_3 = 0 + 3.00\,\Omega = \boxed{3.00\,\Omega}$$

(c) For $R_2 = 6.00\ \Omega$ and $R_3 = 3.00\ \Omega$:

$$R_1 = \frac{3.00\,\Omega + \sqrt{(3.00\,\Omega)^2 + 4(6.00\,\Omega)(3.00\,\Omega)}}{2} = \frac{3.00\,\Omega + 9.00\,\Omega}{2} = \boxed{6.00\,\Omega}$$

and

$$R_{ab} = \frac{R_1 R_2}{R_1 + R_2} + R_3 = \frac{(6.00\,\Omega)(6.00\,\Omega)}{6.00\,\Omega + 6.00\,\Omega} + 3.00\,\Omega = \boxed{6.00\,\Omega}$$

Kirchhoff's Rules

81 • [SSM] In Figure 25-59, the battery's emf is 6.00 V and R is 0.500 Ω. The rate of Joule heating in R is 8.00 W. (a) What is the current in the circuit? (b) What is the potential difference across R? (c) What is the resistance r?

Picture the Problem We can relate the current provided by the source to the rate of Joule heating using $P = I^2R$ and use Ohm's law and Kirchhoff's rules to find the potential difference across R and the value of r.

(a) Relate the current I in the circuit to rate at which energy is being dissipated in the form of Joule heat:

$$P = I^2R \Rightarrow I = \sqrt{\frac{P}{R}}$$

Substitute numerical values and evaluate I:

$$I = \sqrt{\frac{8.00\text{ W}}{0.500\,\Omega}} = \boxed{4.00\text{ A}}$$

(*b*) Apply Ohm's law to find V_R:

$$V_R = IR = (4.00\text{ A})(0.500\,\Omega) = \boxed{2.00\text{ V}}$$

(*c*) Apply Kirchhoff's loop rule to obtain:

$$\mathcal{E} - Ir - IR = 0 \Rightarrow r = \frac{\mathcal{E} - IR}{I} = \frac{\mathcal{E}}{I} - R$$

Substitute numerical values and evaluate r:

$$r = \frac{6.00\text{ V}}{4.00\text{ A}} - 0.500\,\Omega = \boxed{1.00\,\Omega}$$

82 • The batteries in the circuit in Figure 25-60 have negligible internal resistance. (*a*) Find the current using Kirchhoff's loop rule. (*b*) Find the power delivered to or supplied by each battery. (*c*) Find the rate of Joule heating in each resistor.

Picture the Problem Assume that the current flows clockwise in the circuit and let $\mathcal{E}_1$ represent the 12.0-V source and $\mathcal{E}_2$ the 6.00-V source. We can apply Kirchhoff's loop rule (conservation of energy) to this series circuit to relate the current to the emfs of the sources and the resistance of the circuit. In Part (*b*) we can find the power delivered or absorbed by each source using $P = \mathcal{E}I$ and in Part (*c*) the rate of Joule heating using $P = I^2R$.

(*a*) Apply Kirchhoff's loop rule to the circuit to obtain:

$$\mathcal{E}_1 - IR_2 - \mathcal{E}_2 - IR_4 = 0$$

Solving for I yields:

$$I = \frac{\mathcal{E}_1 - \mathcal{E}_2}{R_2 + R_4}$$

Substitute numerical values and evaluate I:

$$I = \frac{12.0\text{ V} - 6.00\text{ V}}{2.00\,\Omega + 4.00\,\Omega} = \boxed{1.0\text{ A}}$$

(*b*) Express the power delivered /absorbed by each source in terms of its emf and the current drawn from or forced through it:

$$P_{12} = \mathcal{E}_{12}I = (12.0\text{ V})(1.0\text{ A}) = \boxed{12\text{ W}}$$

and

$$P_6 = \mathcal{E}_6 I = (-6.00\text{ V})(1.0\text{ A}) = \boxed{-6.0\text{ W}}$$

where the minus sign means that this source is absorbing power.

(*c*) Express the rate of Joule heating

$$P_2 = I^2R_2 = (1.0\text{ A})^2(2.00\,\Omega) = \boxed{2.0\text{ W}}$$

in terms of the current through and the resistance of each resistor:

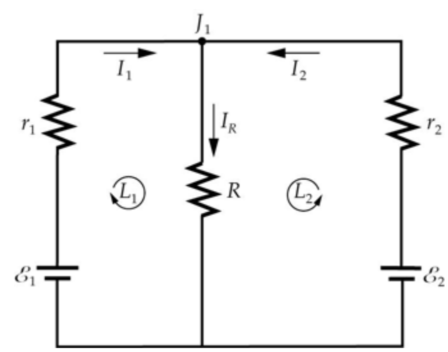
and

$$P_4 = I^2 R_4 = (1.0\,\text{A})^2(4.00\,\Omega) = \boxed{4.0\,\text{W}}$$

83 •• An old car battery that has an emf of $\mathcal{E}$ = 11.4 V and an internal resistance of 50.0 mΩ is connected to a 2.00-Ω resistor. In an attempt to recharge the battery, you connect a second battery that has an emf of $\mathcal{E}$ = 12.6 V and an internal resistance of 10.0 mΩ in parallel with the first battery and the resistor with a pair of jumper cables. (*a*) Draw a diagram of your circuit. (*b*) Find the current in each branch of this circuit. (*c*) Find the power supplied by the second battery and discuss where this power is delivered. Assume that the emfs and internal resistances of both batteries remain constant.

Picture the Problem The circuit is shown in the diagram for Part (*a*). (*b*) Let $\mathcal{E}_1$ and r_1 denote the emf of the old battery and its internal resistance, $\mathcal{E}_2$ and r_2 the emf of the second battery and its internal resistance, and R the load resistance. Let I_1, I_2, and I_R be the currents. We can apply Kirchhoff's rules to determine the unknown currents. (*c*) The power supplied by the second battery is given by $P_2 = (\mathcal{E}_2 - I_2 r_2)I_2$.

(*a*) The circuit diagram is shown to the right:



(*b*) Apply Kirchhoff's junction rule to junction 1 to obtain:

$$I_1 + I_2 = I_R$$

Apply Kirchhoff's loop rule to loop 1 to obtain:

$$\mathcal{E}_1 - r_1 I_1 - RI_R = 0$$

or

$$11.4\,\text{V} - (0.0500\,\Omega)I_1 - (2.00\,\Omega)I_R = 0$$

Apply Kirchhoff's loop rule to loop 2 to obtain:

$$\mathcal{E}_2 - r_2 I_2 - RI_R = 0$$

or

$$12.6\,\text{V} - (0.0100\,\Omega)I_2 - (2.00\,\Omega)I_R = 0$$

Solve the equations in I_1, I_2, and I_R simultaneously to obtain:

$$I_1 = -18.971\ \text{A} = \boxed{-19.0\ \text{A}},$$

$$I_2 = 25.145\ \text{A} = \boxed{25.1\ \text{A}}, \text{ and}$$

$$I_R = 6.174\ \text{A} = \boxed{6.17\ \text{A}}$$

where the minus sign for I_1 means that the current flows in the direction opposite to the direction we arbitrarily chose, i.e., the battery is being charged.

(c) The power supplied by the second battery is given by:

$$P_2 = (\mathcal{E}_2 - I_2 r_2) I_2$$

Substitute numerical values and evaluate P_2:

$$P_2 = [12.6\ \text{V} - (25.145\ \text{A})(10.0\ \text{m}\Omega)] \times (25.145\ \text{A}) = \boxed{311\ \text{W}}$$

The power delivered to the first battery is given by:

$$P_1 = \mathcal{E}_1 I_1 + I_1^2 r_1$$

Substitute numerical values and evaluate P_1:

$$P_1 = (11.4\ \text{V})(18.971\ \text{A}) + (18.971\ \text{A})^2 (0.0500\ \Omega) = 216\ \text{W} + 18.0\ \text{W} = 234\ \text{W}$$

Find the power dissipated in the load resistance R:

$$P_R = I_R^2 R = (6.174\ \text{A})^2 (2.00\ \Omega) = 76.2\ \text{W}$$

In summary, battery 2 supplies 311 W. 234 W is delivered to Battery 1, and of that 234 W, 216 W goes into recharging battery 1 and 18.0 W is dissipated by the internal resistance. In addition, 76.2 W is delivered to the 2.00-Ω resistor.

Remarks: Note that the sum of the power dissipated in the internal and load resistances and that absorbed by the second battery is the same (within round off errors) as that delivered by the first battery … just as we would expect from conservation of energy.

84 •• In the circuit in Figure 25-61, the reading of the ammeter is the same when both switches are open and when both switches are closed. What is the unknown resistance R?

Picture the Problem Note that when both switches are closed the 50.0-Ω resistor is shorted. With both switches open, we can apply Kirchhoff's loop rule to find the current I in the 100-Ω resistor. With the switches closed, the 100-Ω resistor and R are in parallel. Hence, the potential difference across them is the same and we can express the current I_{100} in terms of the current I_{tot} flowing into the parallel branch whose resistance is R, and the resistance of the 100-Ω resistor. I_{tot}, in turn, depends on the equivalent resistance of the closed-switch circuit, so we can express $I_{100} = I$ in terms of R and solve for R.

Apply Kirchhoff's loop rule to a loop around the outside of the circuit with both switches open:

$$\mathcal{E} - (300\,\Omega)I - (100\,\Omega)I - (50.0\,\Omega)I = 0$$

Solving for I yields:

$$I = \frac{\mathcal{E}}{450\,\Omega} = \frac{1.50\,\text{V}}{450\,\Omega} = 3.33\,\text{mA}$$

Relate the potential difference across the 100-Ω resistor to the potential difference across R when both switches are closed:

$$(100\,\Omega)I_{100} = RI_R \qquad (1)$$

Apply Kirchhoff's junction rule at the junction to the left of the 100-Ω resistor and R:

$$I_{tot} = I_{100} + I_R$$
or
$$I_R = I_{tot} - I_{100}$$
where I_{tot} is the current drawn from the source when both switches are closed.

Substituting for I_R in equation (1) yields:

$$(100\,\Omega)I_{100} = R(I_{tot} - I_{100})$$
or
$$I_{100} = \frac{RI_{tot}}{R + 100\,\Omega} \qquad (2)$$

Express the current I_{tot} drawn from the source with both switches closed:

$$I_{tot} = \frac{\mathcal{E}}{R_{eq}}$$

Express the equivalent resistance when both switches are closed:

$$R_{eq} = \frac{(100\,\Omega)R}{R + 100\,\Omega} + 300\,\Omega$$

Substitute for R_{eq} to obtain:

$$I_{tot} = \frac{1.5\,\text{V}}{\dfrac{(100\,\Omega)R}{R + 100\,\Omega} + 300\,\Omega}$$

Substituting for I_{tot} in equation (2) yields:

$$I_{100}=\frac{R}{R+100\,\Omega}\left(\frac{1.50\,\text{V}}{\dfrac{(100\,\Omega)R}{R+100\,\Omega}+300\,\Omega}\right)$$

$$=\frac{(1.50\,\text{V})R}{(400\,\Omega)R+30{,}000\,\Omega^2}=3.33\,\text{mA}$$

Solving for R yields:

$$R=\boxed{600\,\Omega}$$

Remarks: Note that we can also obtain the result in the third step by applying Kirchhoff's loop rule to the parallel branch of the circuit.

85 •• [SSM] In the circuit shown in Figure 25-62, the batteries have negligible internal resistance. Find (*a*) the current in each branch of the circuit, (*b*) the potential difference between point *a* and point *b*, and (*c*) the power supplied by each battery.

Picture the Problem Let I_1 be the current delivered by the left battery, I_2 the current delivered by the right battery, and I_3 the current through the 6.00-Ω resistor, directed down. We can apply Kirchhoff's rules to obtain three equations that we can solve simultaneously for I_1, I_2, and I_3. Knowing the currents in each branch, we can use Ohm's law to find the potential difference between points *a* and *b* and the power delivered by both the sources.

(*a*) Apply Kirchhoff's junction rule at junction *a*:

$$I_{4\Omega}+I_{3\Omega}=I_{6\Omega}\qquad(1)$$

Apply Kirchhoff's loop rule to a loop around the outside of the circuit to obtain:

$$12.0\,\text{V}-(4.00\,\Omega)I_{4\Omega}+(3.00\,\Omega)I_{3\Omega}-12.0\,\text{V}=0$$

or

$$-(4.00\,\Omega)I_{4\Omega}+(3.00\,\Omega)I_{3\Omega}=0\qquad(2)$$

Apply Kirchhoff's loop rule to a loop around the left-hand branch of the circuit to obtain:

$$12.0\,\text{V}-(4.00\,\Omega)I_{4\Omega}-(6.00\,\Omega)I_{6\Omega}=0\qquad(3)$$

Solving equations (1), (2), and (3) simultaneously yields:

$I_{4\Omega}=\boxed{0.667\,\text{A}}$, $I_{3\Omega}=\boxed{0.889\,\text{A}}$,

and

$I_{6\Omega}=\boxed{1.56\,\text{A}}$

(*b*) Apply Ohm's law to find the potential difference between points *a* and *b*:

$$V_{ab} = (6.00\,\Omega)I_{6\Omega} = (6.00\,\Omega)(1.56\,\text{A}) = \boxed{9.36\,\text{V}}$$

(*c*) Express the power delivered by the 12.0-V battery in the left-hand branch of the circuit:

$$P_{\text{left}} = \mathcal{E}\,I_{4\Omega} = (12.0\,\text{V})(0.667\,\text{A}) = \boxed{8.00\,\text{W}}$$

Express the power delivered by the 12.0-V battery in the right-hand branch of the circuit:

$$P_{\text{right}} = \mathcal{E}\,I_{3\Omega} = (12.0\,\text{V})(0.889\,\text{A}) = \boxed{10.7\,\text{W}}$$

86 •• In the circuit shown in Figure 25-63, the batteries have negligible internal resistance. Find (*a*) the current in each branch of the circuit, (*b*) the potential difference between point *a* and point *b*, and (*c*) the power supplied by each battery.

Picture the Problem Let $I_{2\Omega}$ be the current delivered by the 7.00-V battery, $I_{3\Omega}$ the current delivered by the 5-V battery, and $I_{1\Omega}$, directed up, the current through the 1.00-Ω resistor. We can apply Kirchhoff's rules to obtain three equations that we can solve simultaneously for I_1, I_2, and I_3. Knowing the currents in each branch, we can use Ohm's law to find the potential difference between points *a* and *b* and the power delivered by both the sources.

(*a*) Apply Kirchhoff's junction rule at junction *a*:

$$I_{2\Omega} = I_{3\Omega} + I_{1\Omega} \qquad (1)$$

Apply Kirchhoff's loop rule to a loop around the outside of the circuit to obtain:

$$7.00\,\text{V} - (2.00\,\Omega)I_{2\Omega} - (1.00\,\Omega)I_{1\Omega} = 0 \qquad (2)$$

Apply Kirchhoff's loop rule to a loop around the left-hand branch of the circuit to obtain:

$$7.00\,\text{V} - (2.00\,\Omega)I_{2\Omega} - (3.00\,\Omega)I_{3\Omega} + 5.00\,\text{V} = 0$$

or

$$(2.00\,\Omega)I_{2\Omega} + (3.00\,\Omega)I_{3\Omega} = 12.0\,\text{V} \qquad (3)$$

Solve equations (1), (2), and (3) simultaneously to obtain:

$$I_{2\Omega} = \boxed{3.00\,\text{A}},\ I_{3\Omega} = \boxed{2.00\,\text{A}},$$

and

$$I_{1\Omega} = \boxed{1.00\,\text{A}}$$

(*b*) Apply Ohm's law to find the potential difference between points *a* and *b*:

$$V_{ab} = -5.00\,\text{V} + (3.00\,\Omega)I_{3\Omega}$$
$$= -5.00\,\text{V} + (3.00\,\Omega)(2.00\,\text{A})$$
$$= \boxed{1.00\,\text{V}}$$

(*c*) Express the power delivered by the 7.00-V battery:

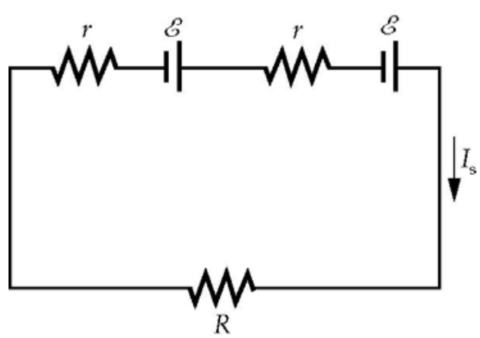
$$P_{7\,\text{V}} = \mathcal{E}\,I_{2\Omega} = (7.00\,\text{V})(3.00\,\text{A})$$
$$= \boxed{21.0\,\text{W}}$$

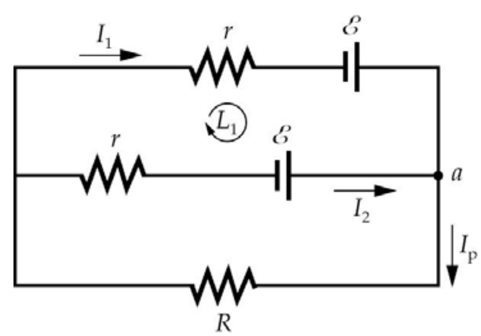
(*c*) Express the power delivered by the 5.00-V battery:

$$P_{5\,\text{V}} = \mathcal{E}\,I_{3\Omega} = (5.00\,\text{V})(2.00\,\text{A})$$
$$= \boxed{10.0\,\text{W}}$$

87 ••• Two identical batteries, each having an emf $\mathcal{E}$ and an internal resistance *r*, can be connected across a resistance *R* with the batteries connected either in series or in parallel. In each situation, determine explicitly whether the power supplied to *R* is greater when *R* is less than *r* or when *R* is greater than *r*.

Picture the Problem The series and parallel connections are shown below. The power supplied to a resistor whose resistance is *R* when the current through it is *I* is given by $P = I^2R$. We can use Kirchhoff's rules to find the currents I_p and I_s and, hence, P_s and P_p, and then use the inequalities $R > r$ and $R < r$ to show that if $R > r$, then $P_p < P_s$ and if $R < r$, then $P_p > P_s$. The steps in the proofs that follow were motivated by having started with the desired outcome and then working backward; for example, assuming that $P_p < P_s$ and showing that $R > r$.





The power P_s supplied to *R* in the series circuit is given by:

$$P_s = I_s^2 R$$

Apply Kirchhoff's loop rule to obtain:

$$-rI_s + \mathcal{E} - rI_s + \mathcal{E} - RI_s = 0$$

Solving for I_s yields:

$$I_s = \frac{2\mathcal{E}}{2r+R}$$

Substitute for I_s and simplify to obtain:

$$P_s = \left(\frac{2\mathcal{E}}{2r+R}\right)^2 R = \frac{4\mathcal{E}^2 R}{(2r+R)^2} \quad (1)$$

The power P_p supplied to R in the series circuit is given by:

$$P_p = I_p^2 R$$

Apply Kirchhoff's junction rule to point a to obtain:

$$I_p = I_1 + I_2$$

Apply Kirchhoff's loop rule to loop 1 to obtain:

$$-rI_1 + \mathcal{E} - \mathcal{E} + rI_2 = 0$$

or

$$I_1 = I_2 = \tfrac{1}{2} I_p$$

Apply Kirchhoff's loop rule to the outer loop to obtain:

$$\mathcal{E} - RI_p - rI_1 = 0$$

or

$$\mathcal{E} - RI_p - \tfrac{1}{2} rI_p = 0 \Rightarrow I_p = \frac{\mathcal{E}}{\tfrac{1}{2}r + R}$$

Substituting for I_p in the expression for P_p yields:

$$P_p = \left(\frac{\mathcal{E}}{\tfrac{1}{2}r+R}\right)^2 R = \frac{\mathcal{E}^2 R}{\left(\tfrac{1}{2}r+R\right)^2} \quad (2)$$

To prove that if $R > r$, then $P_p < P_s$, suppose that $R > r$. Then:

$$3R^2 > 3r^2$$

Adding $r^2 + 4rR + R^2$ to both sides of the inequality yields:

$$r^2 + 4rR + 4R^2 > 4r^2 + 4rR + R^2$$

Factor 4 from the left-hand side and recognize that the right-hand side is the square of a binomial to obtain:

$$4\left(\tfrac{1}{2}r+R\right)^2 > (2r+R)^2$$

or

$$\left(\tfrac{1}{2}r+R\right)^2 > \frac{(2r+R)^2}{4}$$

Taking the reciprocal of both sides of the inequality reverses the sense of the inequality:

$$\frac{1}{\left(\tfrac{1}{2}r+R\right)^2} < \frac{4}{(2r+R)^2}$$

Multiplying both sides of the inequality by $\mathcal{E}^2 R$ yields:

$$\frac{\mathcal{E}^2 R}{\left(\frac{1}{2}r+R\right)^2}<\frac{4\mathcal{E}^2 R}{\left(2r+R\right)^2}$$

For the series combination, the power delivered to the load is greater if $R > r$ and is greatest when $R = 2r$. If $R = r$, both arrangements provide the same power to the load.

To prove that if $R < r$, then $P_{\text{p}} > P_{\text{s}}$, suppose that $R < r$. Then:

$$3R^2 < 3r^2$$

Adding $r^2 + 4rR + R^2$ to both sides of the inequality yields:

$$r^2 + 4rR + 4R^2 < 4r^2 + 4rR + R^2$$

Factor 4 from the left-hand side and recognize that the right-hand side is the square of a binomial to obtain:

$$4\left(\tfrac{1}{2}r+R\right)^2<\left(2r+R\right)^2$$

or

$$\left(\tfrac{1}{2}r+R\right)^2<\frac{\left(2r+R\right)^2}{4}$$

Taking the reciprocal of both sides of the inequality reverses the sense of the inequality:

$$\frac{1}{\left(\frac{1}{2}r+R\right)^2}>\frac{4}{\left(2r+R\right)^2}$$

Multiplying both sides of the inequality by $\mathcal{E}^2 R$ yields:

$$\frac{\mathcal{E}^2 R}{\left(\frac{1}{2}r+R\right)^2}>\frac{4\mathcal{E}^2 R}{\left(2r+R\right)^2}$$

For the parallel combination, the power delivered to the load is greater if $R < r$ and is a maximum when $R = \frac{1}{2}r$.

88 •• The circuit fragment shown in Figure 25-64 is called a *voltage divider*. (*a*) If R_{load} is not attached, show that $V_{\text{out}} = VR_2/(R_1 + R_2)$. (*b*) If $R_1 = R_2 = 10\ \text{k}\Omega$, what is the smallest value of R_{load} that can be used so that V_{out} drops by less than 10 percent from its unloaded value? (V_{out} is measured with respect to ground.)

Picture the Problem Let the current drawn from the source be *I.* We can use Ohm's law in conjunction with Kirchhoff's loop rule to express the output voltage as a function of *V,* R_1, and R_2. In (*b*) we can use the result of (*a*) to express the condition on the output voltages in terms of the effective resistance of the loaded output and the resistances R_1 and R_2.

(*a*) Use Ohm's law to express V_{out} in terms of R_2 and *I*:

$$V_{\text{out}} = IR_2$$

Apply Kirchhoff's loop rule to the circuit to obtain:

$$V - IR_1 - IR_2 = 0 \Rightarrow I = \frac{V}{R_1 + R_2}$$

Substitute for I in the expression for V_{out} to obtain:

$$V_{\text{out}} = \left(\frac{V}{R_1 + R_2}\right) R_2 = \boxed{V\left(\frac{R_2}{R_1 + R_2}\right)}$$

(*b*) Relate the effective resistance of the loaded circuit R_{eff} to R_2 and R_{load}:

$$\frac{1}{R_{\text{eff}}} = \frac{1}{R_2} + \frac{1}{R_{\text{load}}}$$

Solving for R_{load} yields:

$$R_{\text{load}} = \frac{R_2 R_{\text{eff}}}{R_2 - R_{\text{eff}}} \qquad (1)$$

Letting V'_{out} represent the output voltage under load, express the condition that V_{out} drops by less than 10 percent of its unloaded value:

$$\frac{V_{\text{out}} - V'_{\text{out}}}{V_{\text{out}}} = 1 - \frac{V'_{\text{out}}}{V_{\text{out}}} < 0.1 \qquad (2)$$

Using the result from (*a*), express V'_{out} in terms of the effective output load R_{eff}:

$$V'_{\text{out}} = V\left(\frac{R_{\text{eff}}}{R_1 + R_{\text{eff}}}\right)$$

Substitute for V_{out} and V'_{out} in equation (2) and simplify to obtain:

$$1 - \frac{\dfrac{R_{\text{eff}}}{R_1 + R_{\text{eff}}}}{\dfrac{R_2}{R_1 + R_2}} < 0.1$$

or

$$1 - \frac{R_{\text{eff}}(R_1 + R_2)}{R_2(R_1 + R_{\text{eff}})} < 0.1$$

Solving for R_{eff} yields:

$$R_{\text{eff}} > \frac{0.9 R_1 R_2}{R_1 + 0.1 R_2}$$

Substitute numerical values and evaluate R_{eff}:

$$R_{\text{eff}} > \frac{(0.90)(10\,\text{k}\Omega)(10\,\text{k}\Omega)}{10\,\text{k}\Omega + (0.10)(10\,\text{k}\Omega)} = 8.18\,\text{k}\Omega$$

Finally, substitute numerical values in equation (1) and evaluate R_{load}:

$$R_{\text{load}} < \frac{(10\,\text{k}\Omega)(8.18\,\text{k}\Omega)}{10\,\text{k}\Omega - 8.18\,\text{k}\Omega} = \boxed{45\,\text{k}\Omega}$$

89 ••• [SSM] For the circuit shown in Figure 25-65, find the potential difference between point *a* and point *b*.

Picture the Problem Let I_1 be the current in the left branch resistor, directed up; let I_3 be the current, directed down, in the middle branch; and let I_2 be the current in the right branch, directed up. We can apply Kirchhoff's rules to find I_3 and then the potential difference between points *a* and *b*.

Relate the potential at *a* to the potential at *b*:

$$V_a - R_4 I_3 - 4.00\,\text{V} = V_b$$

or

$$V_a - V_b = R_4 I_3 + 4.00\,\text{V} \qquad (1)$$

Apply Kirchhoff's junction rule at *a* to obtain:

$$I_1 + I_2 = I_3 \qquad (2)$$

Apply the loop rule to a loop around the outside of the circuit to obtain:

$$2.00\,\text{V} - (1.00\,\Omega)I_1 + (1.00\,\Omega)I_2 - 2.00\,\text{V} + (1.00\,\Omega)I_2 - (1.00\,\Omega)I_1 = 0$$

or

$$I_1 - I_2 = 0 \qquad (3)$$

Apply the loop rule to the left side of the circuit to obtain:

$$2.00\,\text{V} - (1.00\,\Omega)I_1 - (4.00\,\Omega)I_3 - 4.00\,\text{V} - (1.00\,\Omega)I_1 = 0$$

or

$$-(1.00\,\Omega)I_1 - (2.00\,\Omega)I_3 = 1.00\,\text{V} \quad (4)$$

Solve equations (2), (3), and (4) simultaneously to obtain:

$I_1 = -0.200\,\text{A}$, $I_2 = -0.200\,\text{A}$, and $I_3 = -0.400\,\text{A}$

where the minus signs indicate that the currents flow in opposite directions to the directions chosen.

Substitute numerical values in equation (1) to obtain:

$$V_a - V_b = (4.00\,\Omega)(-0.400\,\text{A}) + 4.00\,\text{V} = \boxed{2.40\,\text{V}}$$

Remarks: Note that point *a* is at the higher potential.

90 ••• For the circuit shown in Figure 25-66, find (*a*) the current in each resistor, (*b*) the power supplied by each source of emf, and (*c*) the power delivered to each resistor.

Picture the Problem Let $I_{1,2\Omega}$ be the current in the 1.00-Ω and 2.00-Ω resistors either side of the 4.00-V source, directed to the right; let $I_{2\Omega}$ be the current, directed up, in the middle branch; and let $I_{6\Omega}$ be the current in the 6.00-Ω resistor, directed down. We can apply Kirchhoff's rules to find these currents, the power supplied by each source, and the power dissipated in each resistor.

(*a*) Apply Kirchhoff's junction rule at the top junction to obtain:

$$I_{1,2\Omega} + I_{2\Omega} = I_{6\Omega} \quad (1)$$

Apply Kirchhoff's loop rule to the outside loop of the circuit to obtain:

$$8.00\,\text{V} - (1.00\,\Omega)I_{1,2\Omega} + 4.00\,\text{V} - (2.00\,\Omega)I_{1,2\Omega} - (6.00\,\Omega)I_{6\Omega} = 0$$

or

$$(3.00\,\Omega)I_{1,2\Omega} + (6.00\,\Omega)I_{6\Omega} = 12.0\,\text{V} \quad (2)$$

Apply the loop rule to the inside loop at the left-hand side of the circuit to obtain:

$$8.00\,\text{V} - (1.00\,\Omega)I_{1,2\Omega} + 4.00\,\text{V} - (2.00\,\Omega)I_{1,2\Omega} + (2.00\,\Omega)I_{2\Omega} - 4.00\,\text{V} = 0$$

or

$$8.00\,\text{V} - (3.00\,\Omega)I_{1,2\Omega} + (2.00\,\Omega)I_{2\Omega} = 0 \quad (3)$$

Solve equations (1), (2), and (3) simultaneously to obtain:

$I_{1,2\Omega} = \boxed{2.00\,\text{A}}$, $I_{2\Omega} = \boxed{-1.00\,\text{A}}$, and $I_{6\Omega} = \boxed{1.00\,\text{A}}$

where the minus sign indicates that the current flows downward rather than upward as we had assumed.

(*b*) The power delivered by the 8.00-V source is:

$$P_{8\,\text{V}} = \mathcal{E}_{8\,\text{V}} I_{1,2\Omega} = (8.00\,\text{V})(2.00\,\text{A}) = \boxed{16.0\,\text{W}}$$

The power delivered by the 4.00-V source is:

$$P_{4\,\text{V}} = \mathcal{E}_{4\,\text{V}} I_{2\Omega} = (4.00\,\text{V})(-1.00\,\text{A}) = \boxed{-4.00\,\text{W}}$$

where the minus sign indicates that this source is having current forced through it and is absorbing power.

(*c*) Express the power dissipated in the 1.00-Ω resistor:

$$P_{1\Omega} = I_{1,2\Omega}^2 R_{1\Omega} = (2.00\,\text{A})^2(1.00\,\Omega) = \boxed{4.00\,\text{W}}$$

Express the power dissipated in the 2.00-Ω resistor in the left branch:

$$P_{2\Omega,\text{left}} = I_{1,2\Omega}^2 R_{2\Omega} = (2.00\,\text{A})^2(2.00\,\Omega) = \boxed{8.00\,\text{W}}$$

Express the power dissipated in the 2.00-Ω resistor in the middle branch:

$$P_{2\Omega,\text{middle}} = I_{2\Omega}^2 R_{2\Omega} = (1.00\,\text{A})^2(2.00\,\Omega) = \boxed{2.00\,\text{W}}$$

Express the power dissipated in the 6.00-Ω resistor:

$$P_{6\Omega} = I_{6\Omega}^2 R_{6\Omega} = (1.00\,\text{A})^2(6.00\,\Omega) = \boxed{6.00\,\text{W}}$$

Ammeters and Voltmeters

91 •• [SSM] The voltmeter shown in Figure 25-67 can be modeled as an ideal voltmeter (a voltmeter that has an infinite internal resistance) in parallel with a 10.0 MΩ resistor. Calculate the reading on the voltmeter when (*a*) R = 1.00 kΩ, (*b*) R = 10.0 kΩ, (*c*) R = 1.00 MΩ, (*d*) R = 10.0 MΩ, and (*e*) R = 100 MΩ. (*f*) What is the largest value of R possible if the measured voltage is to be within 10 percent of the *true* voltage (that is, the voltage drop across R without the voltmeter in place)?

Picture the Problem Let I be the current drawn from source and R_{eq} the resistance equivalent to R and 10 MΩ connected in parallel and apply Kirchhoff's loop rule to express the measured voltage V across R as a function of R.

The voltage measured by the voltmeter is given by:

$$V = IR_{eq} \qquad (1)$$

Apply Kirchhoff's loop rule to the circuit to obtain:

$$10.0\,\text{V} - IR_{eq} - I(2R) = 0$$

Solving for I yields:

$$I = \frac{10.0\,\text{V}}{R_{eq} + 2R}$$

Express R_{eq} in terms of R and 10.0-MΩ resistance in parallel with it:

$$\frac{1}{R_{eq}} = \frac{1}{10.0\,\text{M}\Omega} + \frac{1}{R}$$

Solving for R_{eq} yields:

$$R_{eq} = \frac{(10.0\,\text{M}\Omega)R}{R + 10.0\,\text{M}\Omega}$$

Substitute for I in equation (1) and simplify to obtain:

$$V = \left(\frac{10.0\,\text{V}}{R_{eq} + 2R}\right)R_{eq} = \frac{10.0\,\text{V}}{1 + \dfrac{2R}{R_{eq}}}$$

Substitute for R_{eq} and simplify to obtain:

$$V = \frac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{R + 15.0\,\text{M}\Omega} \qquad (2)$$

(a) Evaluate equation (2) for $R = 1.00\ \text{k}\Omega$:

$$V = \frac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{1.00\,\text{k}\Omega + 15.0\,\text{M}\Omega} = \boxed{3.3\,\text{V}}$$

(b) Evaluate equation (2) for $R = 10.0\ \text{k}\Omega$:

$$V = \frac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{10.0\,\text{k}\Omega + 15.0\,\text{M}\Omega} = \boxed{3.3\,\text{V}}$$

(c) Evaluate equation (2) for $R = 1.00\ \text{M}\Omega$:

$$V = \frac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{1.00\,\text{M}\Omega + 15.0\,\text{M}\Omega} = \boxed{3.1\,\text{V}}$$

(d) Evaluate equation (2) for $R = 10.0\ \text{M}\Omega$:

$$V = \frac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{10.0\,\text{M}\Omega + 15.0\,\text{M}\Omega} = \boxed{2.0\,\text{V}}$$

(e) Evaluate equation (2) for $R = 100\ \text{M}\Omega$:

$$V = \frac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{100\,\text{M}\Omega + 15.0\,\text{M}\Omega} = \boxed{0.43\,\text{V}}$$

(f) Express the condition that the measured voltage to be within 10 percent of the *true* voltage V_{true}:

$$\frac{V_{true} - V}{V_{true}} = 1 - \frac{V}{V_{true}} < 0.1$$

Substitute for V and V_{true} to obtain:

$$1 - \frac{\dfrac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{R + 15.0\,\text{M}\Omega}}{IR} < 0.1$$

Because $I = 10.0\ \text{V}/3R$:

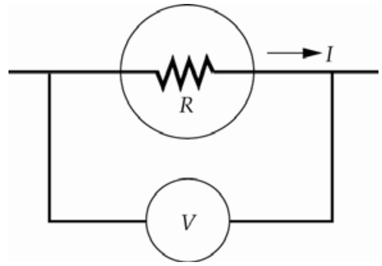
$$1 - \frac{\dfrac{(10.0\,\text{V})(5.0\,\text{M}\Omega)}{R + 15.0\,\text{M}\Omega}}{\dfrac{10.0}{3}\text{V}} < 0.1$$

Solving for R yields:

$$R < \frac{1.5\,\text{M}\Omega}{0.90} = \boxed{1.67\,\text{M}\Omega}$$

92 •• You are given a D'Arsonval galvanometer that will deflect full scale if a current of 50.0 μA runs through the galvanometer. At this current, there is a voltage drop of 0.250 V across the meter. What is the internal resistance of the galvanometer?

Picture the Problem The diagram shows a voltmeter connected in parallel with a galvanometer movement whose internal resistance is *R*. We can apply Kirchhoff's loop rule to express *R* in terms of *I* and *V*.



Apply Kirchhoff's loop rule to the loop that includes the galvanometer movement and the voltmeter:

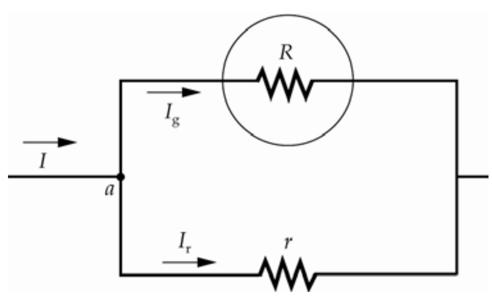
$$V - IR = 0 \Rightarrow R = \frac{V}{I}$$

Substitute numerical values and evaluate *R*:

$$R = \frac{0.250\,\text{V}}{50.0\,\mu\text{A}} = \boxed{5.00\,\text{k}\Omega}$$

93 •• You are given a D'Arsonval galvanometer that will deflect full scale if a current of 50.0 μA runs through the galvanometer. At this current, there is a voltage drop of 0.250 V across the meter. You wish to use this galvanometer to construct an ammeter that can measure currents up to 100 mA. Show that this can be done by placing a resistor in parallel with the meter, and find the value of its resistance.

Picture the Problem When there is a voltage drop of 0.250 V across this galvanometer, the meter reads full scale. The diagram shows the galvanometer movement with a resistor of resistance *r* in parallel. The purpose of this resistor is to limit the current through the movement to I_g = 50.0 μA. We can apply Kirchhoff's loop rule to the circuit fragment containing the galvanometer movement and the shunt resistor to derive an expression for *r*.



Apply Kirchhoff's loop rule to the circuit fragment to obtain:

$$-RI_g + rI_r = 0$$

Apply Kirchhoff's junction rule at point *a* to obtain:

$$I_r = I - I_g$$

Substitute for I_r in the loop equation:

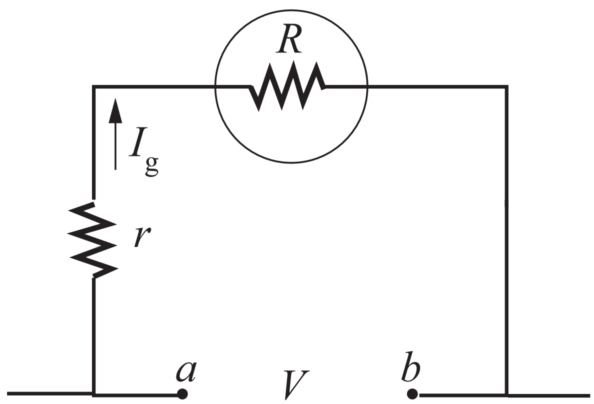
$$-RI_g + r(I - I_g) = 0 \Rightarrow r = \frac{RI_g}{I - I_g}$$

Noting that $RI_g = 0.250$ V, substitute numerical values and evaluate r:

$$r = \frac{0.250\,\text{V}}{100\,\text{mA} - 50.0\,\mu\text{A}} = \boxed{2.5\,\Omega}$$

94 •• You are given a D'Arsonval galvanometer that will deflect full scale if a current of 50.0 μA runs through the galvanometer. At this current, there is a voltage drop of 0.250 V across the meter. You wish to use this galvanometer to construct a voltmeter that can measure potential differences up to 10.0 V. Show that this can be done by placing a large resistance in series with the meter movement, and find the resistance needed.

Picture the Problem The circuit diagram shows a fragment of a circuit in which a resistor of resistance r is connected in series with the meter movement of Problem 92. The purpose of this resistor is to limit the current through the galvanometer movement to 50 μA and to produce a deflection of the galvanometer movement that is a measure of the potential difference V. We can apply Kirchhoff's loop rule to express r in terms of V_g, I_g, and R.



Apply Kirchhoff's loop rule to the circuit fragment to obtain:

$$V - rI_g - RI_g = 0$$

Solving for r yields:

$$r = \frac{V - RI_g}{I_g} = \frac{V}{I_g} - R \qquad (1)$$

Use Ohm's law to relate the current I_g through the galvanometer movement to the potential difference V_g across it:

$$I_g = \frac{V_g}{R} \Rightarrow R = \frac{V_g}{I_g}$$

Use the values for V_g and I_g given in Problem 114 to evaluate R:

$$R = \frac{0.250\,\text{V}}{50.0\,\mu\text{A}} = 5000\,\Omega$$

Substitute numerical values in equation (1) and evaluate r:

$$r = \frac{10.0\,\text{V}}{50.0\,\mu\text{A}} - 5000\,\Omega = \boxed{195\,\text{k}\Omega}$$

Remarks: The total series resistance is the sum of *r* and *R* or 200 kΩ.

RC Circuits

95 • For the circuit shown in Figure 25-68, $C = 6.00\text{-}\mu\text{F}$, $\mathcal{E} = 100$ V and $R = 500\ \Omega$. After having been at contact a for a long time, the switch throw is rotated to contact b. (a) What is the charge on the upper plate capacitor just as the switch throw is moved to contact b? (b) What is the current just after the switch throw is rotated to contact b? (c) What is the time constant of this circuit? (d) How much charge is on the upper plate of the capacitor 6.00 ms after the switch throw is rotated to contact b?

Picture the Problem We can use the definition of capacitance to find the initial charge on the capacitor and Ohm's law to find the initial current in the circuit. We can find the time constant of the circuit using its definition and the charge on the capacitor after 6.00 ms using $Q(t) = Q_0 e^{-t/\tau}$.

(a) Use the definition of capacitance to find the initial charge on the capacitor:

$$Q_0 = CV_0 = (6.00\,\mu\text{F})(100\,\text{V}) = \boxed{600\,\mu\text{C}}$$

(b) Apply Ohm's law to the resistor to obtain:

$$I_0 = \frac{V_0}{R} = \frac{100\,\text{V}}{500\,\Omega} = \boxed{0.200\,\text{A}}$$

(c) Use its definition to find the time constant of the circuit:

$$\tau = RC = (500\,\Omega)(6.00\,\mu\text{F}) = \boxed{3.00\,\text{ms}}$$

(d) Express the charge on the capacitor as a function of time:

$$Q(t) = Q_0 e^{-t/\tau}$$

Substitute numerical values and evaluate Q(6 ms):

$$Q(6.00\,\text{ms}) = (600\,\mu\text{C})e^{-6.00\,\text{ms}/3.00\,ms} = \boxed{81.2\,\mu\text{C}}$$

96 • At $t = 0$ the switch throw in Figure 25-68 is rotated to contact b after having been at contact a for a long time. (a) How much energy is stored in the capacitor at $t = 0$? (b) For $t > 0$, find the energy stored in the capacitor as a function of time, and (c) sketch a plot of the energy stored in the capacitor versus time t.

Picture the Problem (*a*) The initial energy stored in the capacitor is given by $U_0 = \frac{1}{2}C\mathcal{E}^2$. (*b*) The energy stored in the capacitor as a function of time is given by $U(t) = \frac{1}{2}C(V_C(t))^2$ where $V_C(t) = V_0 e^{-t/\tau}$.

(*a*) The initial energy stored in the capacitor is given by:

$$U_0 = \tfrac{1}{2}(6.00\ \mu\text{F})(100\ \text{V})^2 = \boxed{30.0\ \text{mJ}}$$

(*b*) Express the energy stored in the discharging capacitor as a function of time:

$$U(t) = \tfrac{1}{2}C(V_C(t))^2$$

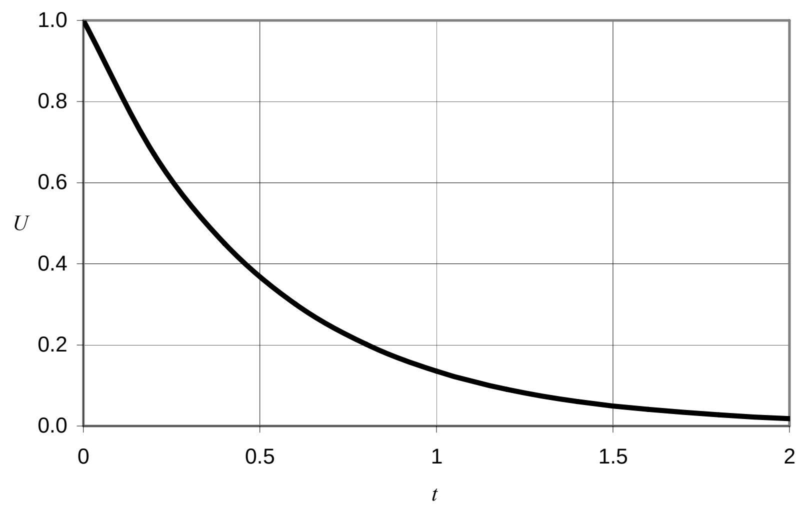
where

$$V_C(t) = \mathcal{E}\, e^{-t/\tau}$$

Substitute for $V_C(t)$ and simplify to obtain:

$$U(t) = \tfrac{1}{2}C\left(\mathcal{E}\, e^{-t/\tau}\right)^2 = \tfrac{1}{2}C\mathcal{E}^2 e^{-2t/\tau} = \boxed{U_0 e^{-2t/\tau}}$$

(*c*) A graph of *U* versus *t* is shown below. *U* is in units of U_0 and *t* is in units of τ.



97 •• **[SSM]** In the circuit in Figure 25-69, the emf equals 50.0 V and the capacitance equals 2.00 μF. Switch *S* is opened after having been closed for a long time, and 4.00 s later the voltage drop across the resistor is 20.0 V. Find the resistance of the resistor.

Picture the Problem We can find the resistance of the circuit from its time constant and use Ohm's law and the expression for the current in a charging *RC* circuit to express τ as a function of time, V_0 and $V(t)$.

Express the resistance of the resistor in terms of the time constant of the circuit:

$$R = \frac{\tau}{C} \qquad (1)$$

Using Ohm's law, express the voltage drop across the resistor as a function of time:

$$V(t) = I(t)R$$

Express the current in the circuit as a function of the elapsed time after the switch is closed:

$$I(t) = I_0 e^{-t/\tau}$$

Substitute for $I(t)$ to obtain:

$$V(t) = I_0 e^{-t/\tau} R = (I_0 R)e^{-t/\tau} = V_0 e^{-t/\tau}$$

Take the natural logarithm of both sides of the equation and solve for τ to obtain:

$$\tau = -\frac{t}{\ln\left[\frac{V(t)}{V_0}\right]}$$

Substitute for τ in equation (1) to obtain:

$$R = -\frac{t}{C\ln\left[\frac{V(t)}{V_0}\right]}$$

Substitute numerical values and evaluate R using the data given for $t = 4.00$ s:

$$R = -\frac{4.00\,\text{s}}{(2.00\,\mu\text{F})\ln\left(\frac{20.0\,\text{V}}{50.0\,\text{V}}\right)} = \boxed{2.18\,\text{M}\Omega}$$

98 •• For the circuit shown in Figure 25-68, $C = 0.120\ \mu$F and $\mathcal{E} = 100$ V. The switch throw is rotated to contact b after having been at contact a for a long time, and 4.00 s later the potential difference across the capacitor is equal to $\frac{1}{2}\mathcal{E}$. What is the value of R?

Picture the Problem We can find the resistance of the circuit from its time constant and use the expression for the charge on a discharging capacitor as a function of time to express τ as a function of time, V_0, and $V(t)$.

Express the effective resistance across the capacitor in terms of the time constant of the circuit:

$$R = \frac{\tau}{C} \qquad (1)$$

Express the voltage across the capacitor as a function of the elapsed time after the switch is closed:

$$V(t) = V_0 e^{-t/\tau}$$

Take the natural logarithm of both sides of the equation and solve for τ to obtain:

$$\tau = -\frac{t}{\ln\left(\frac{V(t)}{V_0}\right)}$$

Substitute for τ in equation (1) to obtain:

$$R = -\frac{t}{C\ln\left(\frac{V(t)}{V_0}\right)}$$

Substitute numerical values and evaluate R:

$$R = -\frac{4.00\,\text{s}}{(0.120\,\mu\text{F})\ln\left(\frac{\frac{1}{2}V_0}{V_0}\right)} = \boxed{48.1\,\text{M}\Omega}$$

99 •• In the circuit in Figure 25-70, the emf equals 6.00 V and has negligible internal resistance. The capacitance equals 1.50 μF and the resistance equals 2.00-MΩ. Switch S has been closed for a long time. Switch S is opened. After a time interval equal to one time constant of the circuit has elapsed, find: (*a*) the charge on the capacitor plate on the right, (*b*) the rate at which the charge is increasing, (*c*) the current, (*d*) the power supplied by the battery, (*e*) the power delivered to the resistor, and (*f*) the rate at which the energy stored in the capacitor is increasing.

Picture the Problem We can use $Q(t) = Q_\text{f}\left(1 - e^{-t/\tau}\right) = C\mathcal{E}\left(1 - e^{-t/\tau}\right)$ to find the charge on the capacitor at $t = \tau$ and differentiate this expression with respect to time to find the rate at which the charge is increasing (the current). The power supplied by the battery is given by $P_\tau = I_\tau \mathcal{E}$ and the power dissipated in the resistor by $P_{R,\tau} = I_\tau^2 R$. In Part (*f*) we can differentiate $U(t) = Q^2(t)/2C$ with respect to time and evaluate the derivative at $t = \tau$ to find the rate at which the energy stored in the capacitor is increasing.

(*a*) Express the charge Q on the capacitor as a function of time:

$$Q(t) = Q_\text{f}\left(1 - e^{-t/\tau}\right) = C\mathcal{E}\left(1 - e^{-t/\tau}\right) \quad (1)$$

where $\tau = RC$.

Evaluate $Q(\tau)$ to obtain:

$$Q(\tau) = (1.50\,\mu\text{F})(6.00\,\text{V})\left(1 - e^{-1}\right) = 5.689\,\mu\text{C} = \boxed{5.69\,\mu\text{C}}$$

(*b*) and (*c*) Differentiate equation (1) with respect to *t* to obtain:

$$\frac{dQ(t)}{dt} = I(t) = I_0 e^{-t/\tau}$$

Apply Kirchhoff's loop rule to the circuit just after the circuit is completed to obtain:

$$\mathcal{E} - RI_0 - V_{C0} = 0$$

Because $V_{C0} = 0$ we have:

$$I_0 = \frac{\mathcal{E}}{R}$$

Substituting for I_0 yields:

$$\frac{dQ(t)}{dt} = I(t) = \frac{\mathcal{E}}{R} e^{-t/\tau}$$

Substitute numerical values and evaluate $\frac{dQ(t)}{dt} = I(t)$:

$$\frac{dQ(t)}{dt} = I(t) = \frac{6.00\,\text{V}}{2.00\,\text{M}\Omega} e^{-1}$$

$$= 1.104\,\mu\text{C/s} = \boxed{1.10\,\mu\text{C/s}}$$

(*d*) Express the power supplied by the battery as the product of its emf and the current drawn from it at $t = \tau$:

$$P(\tau) = I(\tau)\mathcal{E} = (1.104\,\mu\text{A})(6.00\,\text{V})$$

$$= \boxed{6.62\,\mu\text{W}}$$

(*e*) The power dissipated in the resistor is given by:

$$P_R(\tau) = I^2(\tau)R = (1.104\,\mu\text{A})^2(2.00\,\text{M}\Omega)$$

$$= \boxed{2.44\,\mu\text{W}}$$

(*f*) Express the energy stored in the capacitor as a function of time:

$$U(t) = \frac{Q^2(t)}{2C}$$

Differentiate this expression with respect to time to obtain:

$$\frac{dU(t)}{dt} = \frac{1}{2C}\frac{d}{dt}\left[Q^2(t)\right]$$

$$= \frac{1}{2C}(2Q(t))\frac{dQ(t)}{dt}$$

$$= \frac{Q(t)}{C} I(t)$$

Evaluate $\frac{dU(t)}{dt}$ when $t = \tau$ to obtain:

$$\frac{dU(\tau)}{dt} = \frac{5.689\,\mu\text{C}}{1.50\,\mu\text{F}}(1.104\,\mu\text{A})$$

$$= \boxed{4.19\,\mu\text{W}}$$

Remarks: Note that our answer for Part (*f*) is the difference between the power delivered by the battery at $t = \tau$ and the rate at which energy is dissipated in the resistor at the same time.

100 •• A constant charge of 1.00 mC is on the positively charged plate of the 5.00-μF capacitor in the circuit shown in Figure 25-70. Find (*a*) the battery current, and (*b*) the resistances R_1, R_2, and R_3.

Picture the Problem We can apply Kirchhoff's junction rule to find the current in each branch of this circuit and then use the loop rule to obtain equations solvable for R_1, R_2, and R_3.

(*a*) Apply Kirchhoff's junction rule at the junction of the 5.00-μF capacitor and the 10.0-Ω and 50.0-Ω resistors under steady-state conditions:

$$I_{\text{bat}} = I_{10\,\Omega} + 5.00\,\text{A} \qquad (1)$$

Because the potential differences across the 5.00-μF capacitor and the 10.0-Ω resistor are the same:

$$I_{10\Omega} = \frac{V_{10\,\Omega}}{10.0\,\Omega} = \frac{V_{\text{C}}}{10.0\,\Omega}$$

Express the potential difference across the capacitor to its steady-state charge:

$$V_{\text{C}} = \frac{Q_{\text{f}}}{C}$$

Substitute for V_{C} to obtain:

$$I_{10\Omega} = \frac{Q_{\text{f}}}{(10.0\,\Omega)C}$$

Substitute in equation (1) to obtain:

$$I_{\text{bat}} = \frac{Q_{\text{f}}}{(10.0\,\Omega)C} + 5.00\,\text{A}$$

Substitute numerical values and evaluate I_{bat}:

$$I_{\text{bat}} = \frac{1000\,\mu\text{C}}{(10.0\,\Omega)(5.00\,\mu\text{F})} + 5.00\,\text{A} = \boxed{25.0\,\text{A}}$$

(*b*) Use Kirchhoff's junction rule to find the currents $I_{5\,\Omega}$, I_{R3}, and I_{R1}:

$I_{5\Omega} = 10.0\,\text{A}$, $I_{R3} = 15.0\,\text{A}$, and
$I_{R1} = I_{\text{bat}} = 25.0\,\text{A}$

Apply the loop rule to the loop that includes the battery, R_1, and the 50.0-Ω and 5.00-Ω resistors:

$$310\,\text{V} - (25.0\,\text{A})R_1 - (5.00\,\text{A})(50.0\,\Omega) - (10.0\,\text{A})(5.00\,\Omega) = 0$$

Solve for R_1 to obtain:

$$R_1 = \boxed{0.400\,\Omega}$$

Apply the loop rule to the loop that includes the battery, R_1, the 10.0-Ω resistor and R_3:

$$310\,\text{V} - (25.0\,\text{A})(0.400\,\Omega) - (20.0\,\text{A})(10.0\,\Omega) - (15.0\,\text{A})R_3 = 0$$

Solving for R_3 yields:

$$R_3 = \boxed{6.67\,\Omega}$$

Apply the loop rule to the loop that includes the 10.0-Ω and 50.0-Ω resistors and R_2:

$$-(20.0\,\text{A})(10.0\,\Omega) - (5.00\,\text{A})R_2 + (5.00\,\text{A})(50.0\,\Omega) = 0$$

Solving for R_2 yields:

$$R_2 = \boxed{10.0\,\Omega}$$

101 •• Show that Equation 25-39 can be rearranged and written as $\dfrac{dQ}{\mathcal{E}C - Q} = \dfrac{dt}{RC}$. Integrate this equation to derive the solution given by Equation 25-40.

Picture the Problem We can separate the variables in Equation 25-39 to obtain the equation given in the problem statement. Integrating this differential equation will yield Equation 25-40.

Solve Equation 25-39 for dQ/dt to obtain:

$$\frac{dQ}{dt} = \frac{\mathcal{E}C - Q}{RC}$$

Separate the variables to obtain:

$$\boxed{\frac{dQ}{\mathcal{E}C - Q} = \frac{dt}{RC}}$$

Integrate dQ' from 0 to Q and dt' from 0 to t:

$$\int_0^Q \frac{dQ'}{\mathcal{E}C - Q'} = \frac{1}{RC}\int_0^t dt'$$

and

$$\ln\left(\frac{\mathcal{E}C}{\mathcal{E}C - Q}\right) = \frac{t}{RC}$$

Transform from logarithmic to exponential form to obtain:

$$\frac{\mathcal{E}C}{\mathcal{E}C-Q}=e^{\frac{t}{RC}}$$

Solve for Q to obtain Equation 25-40:

$$Q=\mathcal{E}C\left(1-e^{-t/RC}\right)=\boxed{Q_{\mathrm{f}}\left(1-e^{-t/RC}\right)}$$

102 •• Switch S, shown in Figure 25-71, is closed after having been open for a long time. (*a*) What is the initial value of the battery current just after switch S is closed? (*b*) What is the battery current a long time after switch S is closed? (*c*) What are the charges on the plates of the capacitors a long time after switch S is closed? (*d*) Switch S is reopened. What are the charges on the plates of the capacitors a long time after switch *S* is reopened?

Picture the Problem When the switch is closed, the initial potential differences across the capacitors are zero (they have no charge) and the resistors in the bridge portion of the circuit are in parallel. When a long time has passed, the current through the capacitors will be zero and the resistors will be in series. In both cases, the application of Kirchhoff's loop rule to the entire circuit will yield the current in the circuit. To find the final charges on the capacitors we can use the definition of capacitance and apply Kirchhoff's loop rule to the loops containing two resistors and a capacitor to find the potential differences across the capacitors.

(*a*) Apply Kirchhoff's loop rule to the circuit immediately after the switch is closed:

$$50.0\,\mathrm{V}-I_0(10.0\,\Omega)-I_0R_{\mathrm{eq}}=0$$

Solving for I_0 yields:

$$I_0=\frac{50.0\,\mathrm{V}}{10.0\,\Omega+R_{\mathrm{eq}}}$$

Find the equivalent resistance of 15.0 Ω, 12.0 Ω, and 15.0 Ω in parallel:

$$\frac{1}{R_{\mathrm{eq}}}=\frac{1}{15.0\,\Omega}+\frac{1}{12.0\,\Omega}+\frac{1}{15.0\,\Omega}$$

and

$$R_{\mathrm{eq}}=4.615\,\Omega$$

Substitute for R_{eq} and evaluate I_0:

$$I_0=\frac{50.0\,\mathrm{V}}{10.0\,\Omega+4.615\,\Omega}=\boxed{3.42\,\mathrm{A}}$$

(*b*) Apply Kirchhoff's loop rule to the circuit a long time after the switch is closed:

$$50.0\,\mathrm{V}-I_\infty(10.0\,\Omega)-I_\infty R_{\mathrm{eq}}=0$$

Solving for I_∞ yields:

$$I_\infty = \frac{50.0\,\text{V}}{10.0\,\Omega + R_{\text{eq}}}$$

Find the equivalent resistance of 15.0 Ω, 12.0 Ω, and 15.0 Ω in series:

$$R_{\text{eq}} = 15.0\,\Omega + 12.0\,\Omega + 15.0\,\Omega = 42.0\,\Omega$$

Substitute for R_{eq} and evaluate I_∞:

$$I_\infty = \frac{50.0\,\text{V}}{10.0\,\Omega + 42.0\,\Omega} = \boxed{0.962\,\text{A}}$$

(*c*) Using the definition of capacitance, express the charge on the capacitors in terms of their final potential differences:

$$Q_{10\,\mu\text{F}} = C_{10\,\mu\text{F}} V_{10\,\mu\text{F}} \qquad (1)$$

and

$$Q_{5\,\mu\text{F}} = C_{5\,\mu\text{F}} V_{5\,\mu\text{F}} \qquad (2)$$

Apply Kirchhoff's loop rule to the loop containing the 15.0-Ω and 12.0-Ω resistors and the 10.0 μF capacitor to obtain:

$$V_{10\,\mu\text{F}} - (15.0\,\Omega)I_\infty - (12.0\,\Omega)I_\infty = 0$$

Solving for $V_{10\,\mu\text{F}}$ yields:

$$V_{10\,\mu\text{F}} = (27.0\,\Omega)I_\infty$$

Substitute numerical values in equation (1) and evaluate $Q_{10\,\mu\text{F}}$:

$$Q_{10\,\mu\text{F}} = (10.0\,\mu\text{F})(27.0\,\Omega)(0.962\,\text{A}) = \boxed{260\,\mu\text{C}}$$

Apply Kirchhoff's loop rule to the loop containing the 15.0-Ω and 12.0-Ω resistors and the 5.00 μF capacitor to obtain:

$$V_{5\,\mu\text{F}} - (15.0\,\Omega)I_\infty - (12.0\,\Omega)I_\infty = 0$$

Solve for $V_{5\,\mu\text{F}}$:

$$V_{5\,\mu\text{F}} = (27.0\,\Omega)I_\infty$$

Substitute numerical values in equation (2) and evaluate $Q_{5\,\mu\text{F}}$:

$$Q_{5\,\mu\text{F}} = (5.00\,\mu\text{F})(27.0\,\Omega)(0.962\,\text{A}) = \boxed{130\,\mu\text{C}}$$

(*d*) The charges on the plates of the capacitors a long time after switch S is reopened will be 0.

103 ••• In the circuit shown in Figure 25-72, switch S has been open for a long time. At time $t = 0$ the switch is then closed. (*a*) What is the battery current just after switch S is closed? (*b*) What is the battery current a long time after switch S is closed? (*c*) What is the current in the 600-Ω resistor as a function of time?

Picture the Problem Let $R_1 = 200\ \Omega$, $R_2 = 600\ \Omega$, I_1 and I_2 their currents, and I_3 the current into the capacitor. We can apply Kirchhoff's loop rule to find the initial battery current I_0 and the battery current I_∞ a long time after the switch is closed. In Part (*c*) we can apply both the loop and junction rules to obtain equations that we can use to obtain a linear differential equation with constant coefficients describing the current in the 600-Ω resistor as a function of time. We can solve this differential equation by assuming a solution of a given form, differentiating this assumed solution and substituting it and its derivative in the differential equation. Equating coefficients, requiring the solution to hold for all values of the assumed constants, and invoking an initial condition will allow us to find the constants in the assumed solution.

(*a*) Apply Kirchhoff's loop rule to the circuit at the instant the switch is closed:

$$\mathcal{E} - (200\,\Omega)I_0 - V_{C0} = 0$$

Because the capacitor is initially uncharged:

$$V_{C0} = 0$$

Solve for and evaluate I_0:

$$I_0 = \frac{\mathcal{E}}{200\,\Omega} = \frac{50.0\,\text{V}}{200\,\Omega} = \boxed{0.250\,\text{A}}$$

(*b*) Apply Kirchhoff's loop rule to the circuit after a long time has passed:

$$50.0\,\text{V} - (200\,\Omega)I_\infty - (600\,\Omega)I_\infty = 0$$

Solve for I_∞ to obtain:

$$I_\infty = \frac{50.0\,\text{V}}{800\,\Omega} = \boxed{62.5\,\text{mA}}$$

(*c*) Apply the junction rule at the junction between the 200-Ω resistor and the capacitor to obtain:

$$I_1 = I_2 + I_3 \qquad (1)$$

Apply the loop rule to the loop containing the source, the 200-Ω resistor and the capacitor to obtain:

$$\mathcal{E} - R_1 I_1 - \frac{Q}{C} = 0 \qquad (2)$$

Apply the loop rule to the loop containing the 600-Ω resistor and the capacitor to obtain:

$$\frac{Q}{C} - R_2 I_2 = 0 \qquad (3)$$

Differentiate equation (2) with respect to time to obtain:

$$\frac{d}{dt}\left[\mathcal{E} - R_1 I_1 - \frac{Q}{C}\right] = 0 - R_1\frac{dI_1}{dt} - \frac{1}{C}\frac{dQ}{dt}$$

$$= -R_1\frac{dI_1}{dt} - \frac{1}{C}I_3 = 0$$

or

$$R_1\frac{dI_1}{dt} = -\frac{1}{C}I_3 \qquad (4)$$

Differentiate equation (3) with respect to time to obtain:

$$\frac{d}{dt}\left[\frac{Q}{C} - R_2 I_2\right] = \frac{1}{C}\frac{dQ}{dt} - R_2\frac{dI_2}{dt} = 0$$

or

$$R_2\frac{dI_2}{dt} = \frac{1}{C}I_3 \qquad (5)$$

Using equation (1), substitute for I_3 in equation (5) to obtain:

$$\frac{dI_2}{dt} = \frac{1}{R_2 C}\left(I_1 - I_2\right) \qquad (6)$$

Solve equation (2) for I_1:

$$I_1 = \frac{\mathcal{E} - Q/C}{R_1} = \frac{\mathcal{E} - R_2 I_2}{R_1}$$

Substitute for I_1 in equation (6) and simplify to obtain the differential equation for I_2:

$$\frac{dI_2}{dt} = \frac{1}{R_2 C}\left(\frac{\mathcal{E} - R_2 I_2}{R_1} - I_2\right)$$

$$= \frac{\mathcal{E}}{R_1 R_2 C} - \left(\frac{R_1 + R_2}{R_1 R_2 C}\right) I_2$$

To solve this linear differential equation with constant coefficients we can assume a solution of the form:

$$I_2(t) = a + be^{-t/\tau} \qquad (7)$$

Differentiate $I_2(t)$ with respect to time to obtain:

$$\frac{dI_2}{dt} = \frac{d}{dt}\left[a + be^{-t/\tau}\right] = -\frac{b}{\tau}e^{-t/\tau}$$

Substitute for I_2 and dI_2/dt to obtain:

$$-\frac{b}{\tau}e^{-t/\tau} = \frac{\varepsilon}{R_1R_2C} - \left(\frac{R_1+R_2}{R_1R_2C}\right)\left(a + be^{-t/\tau}\right)$$

Equate coefficients of $e^{-t/\tau}$ to obtain:

$$\tau = \frac{R_1R_2C}{R_1+R_2}$$

Requiring the equation to hold for all values of a yields:

$$a = \frac{\varepsilon}{R_1+R_2}$$

If I_2 is to be zero when $t = 0$:

$$0 = a + b \Rightarrow b = -a = -\frac{\varepsilon}{R_1+R_2}$$

Substitute in equation (7) to obtain:

$$I_2(t) = \frac{\varepsilon}{R_1+R_2} - \frac{\varepsilon}{R_1+R_2}e^{-t/\tau}$$
$$= \frac{\varepsilon}{R_1+R_2}\left(1 - e^{-t/\tau}\right)$$

where

$$\tau = \frac{R_1R_2C}{R_1+R_2} = \frac{(200\,\Omega)(600\,\Omega)(5.00\,\mu\text{F})}{200\,\Omega + 600\,\Omega}$$
$$= 0.750\,\text{ms}$$

Substitute numerical values and evaluate $I_2(t)$:

$$I_2(t) = \frac{50.0\,\text{V}}{200\,\Omega + 600\,\Omega}\left(1 - e^{-t/0.750\,\text{ms}}\right)$$
$$= \boxed{(62.5\,\text{mA})\left(1 - e^{-t/0.750\,\text{ms}}\right)}$$

104 ••• In the circuit shown in Figure 25-72, switch S has been open for a long time. At time t =0 the switch is then closed. (*a*) What is the battery current just after switch S is closed? (*b*) What is the battery current a long time after switch S is closed? (*c*) The switch has been closed for a long time. At t =0 the switch is then opened. Find the current through the 600-kΩ resistor as a function of time.

Picture the Problem Let R_1 represent the 1.20-MΩ resistor and R_2 the 600-kΩ resistor. Immediately after switch S is closed, the capacitor has zero charge and so the potential difference across it (and the 600 kΩ-resistor) is zero. A long time after the switch is closed, the capacitor will be fully charged and the potential difference across it will be given by both Q/C and $I_\infty R_2$. When the switch is opened after having been closed for a long time, both the source and the

1.20-MΩ resistor will be out of the circuit and the fully charged capacitor will discharge through R_2. We can use Kirchhoff's loop to find the currents drawn from the source immediately after the switch is closed and a long time after the switch is closed, as well as the current in the RC circuit when the switch is again opened and the capacitor discharges through R_2.

(*a*) Apply Kirchhoff's loop rule to the circuit immediately after the switch is closed to obtain:

$$\mathcal{E} - I_0R_1 - V_{C0} = 0$$

or, because $V_{C0} = 0$,

$$\mathcal{E} - I_0R_1 = 0 \Rightarrow I_0 = \frac{\mathcal{E}}{R_1}$$

Substitute numerical values and evaluate I_0:

$$I_0 = \frac{50.0\,\text{V}}{1.20\,\text{M}\Omega} = \boxed{41.7\,\mu\text{A}}$$

(*b*) Apply Kirchhoff's loop rule to the circuit a long time after the switch is closed to obtain:

$$\mathcal{E} - I_\infty R_1 - I_\infty R_2 = 0 \Rightarrow I_\infty = \frac{\mathcal{E}}{R_1 + R_2}$$

Substitute numerical values and evaluate I_∞:

$$I_\infty = \frac{50.0\,\text{V}}{1.20\,\text{M}\Omega + 600\,\text{k}\Omega} = \boxed{27.8\,\mu\text{A}}$$

(*c*) Apply Kirchhoff's loop rule to the RC circuit sometime after the switch is opened and solve for $I(t)$ to obtain:

$$V_C(t) - R_2I(t) = 0 \Rightarrow I(t) = \frac{V_C(t)}{R_2}$$

Substituting for $V_C(t)$ yields:

$$I(t) = \frac{V_{C\infty}}{R_2}e^{-t/\tau} = I_\infty e^{-t/\tau}$$

where $\tau = R_2C$.

Substitute numerical values to obtain:

$$I(t) = (27.8\,\mu\text{A})e^{-t/(600\,\text{k}\Omega)(2.50\,\mu\text{F})}$$
$$= \boxed{(27.8\,\mu\text{A})e^{-t/1.50\,\text{s}}}$$

105 ••• [SSM] In the circuit shown in Figure 25-74, the capacitor has a capacitance of 2.50 μF and the resistor has a resistance of 0.500 MΩ. Before the switch is closed, the potential drop across the capacitor is 12.0 V, as shown. Switch S is closed at $t = 0$. (*a*) What is the current immediately after switch S is closed? (*b*) At what time t is the voltage across the capacitor 24.0 V?

Picture the Problem We can apply Kirchhoff's loop rule to the circuit immediately after the switch is closed in order to find the initial current I_0. We

can find the time at which the voltage across the capacitor is 24.0 V by again applying Kirchhoff's loop rule to find the voltage across the resistor when this condition is satisfied and then using the expression $I(t)=I_0e^{-t/\tau}$ for the current through the resistor as a function of time and solving for t.

(*a*) Apply Kirchhoff's loop rule to the circuit immediately after the switch is closed:

$$\mathcal{E}-12.0\,\text{V}-I_0R=0$$

Solving for I_0 yields:

$$I_0=\frac{\mathcal{E}-12.0\,\text{V}}{R}$$

Substitute numerical values and evaluate I_0:

$$I_0=\frac{36.0\,\text{V}-12.0\,\text{V}}{0.500\,\text{M}\Omega}=\boxed{48.0\,\mu\text{A}}$$

(*b*) Apply Kirchhoff's loop rule to the circuit when V_C = 24.0 V and solve for V_R:

$$36.0\,\text{V}-24.0\,\text{V}-I(t)R=0$$

and

$$I(t)R=12.0\,\text{V}$$

Express the current through the resistor as a function of I_0 and τ:

$I(t)=I_0e^{-t/\tau}$ where $\tau=RC$.

Substitute to obtain:

$$RI_0e^{-t/\tau}=12.0\,\text{V}\Rightarrow e^{-t/\tau}=\frac{12.0\,\text{V}}{RI_0}$$

Take the natural logarithm of both sides of the equation to obtain:

$$-\frac{t}{\tau}=\ln\left(\frac{12.0\,\text{V}}{RI_0}\right)$$

Solving for t yields:

$$t=-\tau\ln\left(\frac{12.0\,\text{V}}{RI_0}\right)=-RC\ln\left(\frac{12.0\,\text{V}}{RI_0}\right)$$

Substitute numerical values and evaluate t:

$$t=-(0.500\,\text{M}\Omega)(2.50\,\mu\text{F})\ln\left[\frac{12.0\,\text{V}}{(0.500\,\text{M}\Omega)(48.0\,\mu\text{A})}\right]=\boxed{0.866\,\text{s}}$$

106 ••• Repeat Problem 105 if the initial polarity of the capacitor opposite to that shown in Figure 25-74.

Picture the Problem We can apply Kirchhoff's loop rule to the circuit immediately after the switch is closed in order to find the initial current I_0. We can find the time at which the voltage across the capacitor is 24.0 V by again applying Kirchhoff's loop rule to find the voltage across the resistor when this condition is satisfied and then using the expression $I(t)=I_0e^{-t/\tau}$ for the current through the resistor as a function of time and solving for t.

(*a*) Apply Kirchhoff's loop rule to the circuit immediately after the switch is closed:

$$\mathcal{E}+12.0\,\text{V}-I_0R=0 \Rightarrow I_0=\frac{\mathcal{E}+12.0\,\text{V}}{R}$$

Substitute numerical values and evaluate I_0:

$$I_0=\frac{36.0\,\text{V}+12.0\,\text{V}}{0.500\,\text{M}\Omega}=\boxed{96.0\,\mu\text{A}}$$

(*b*) Apply Kirchhoff's loop rule to the circuit when V_C = 24.0 V and solve for V_R:

$$36.0\,\text{V}-24.0\,\text{V}-I(t)R=0$$

and

$$I(t)R=12.0\,\text{V}$$

Express the current through the resistor as a function of I_0 and τ:

$$I(t)=I_0e^{-t/\tau} \text{ where } \tau=RC.$$

Substitute for $I(t)$ to obtain:

$$RI_0e^{-t/\tau}=12.0\,\text{V} \Rightarrow e^{-t/\tau}=\frac{12.0\,\text{V}}{RI_0}$$

Taking the natural logarithm of both sides of the equation yields:

$$-\frac{t}{\tau}=\ln\left(\frac{12.0\,\text{V}}{RI_0}\right)$$

Solving for t yields:

$$t=-\tau\ln\left(\frac{12.0\,\text{V}}{RI_0}\right)=-RC\ln\left(\frac{12.0\,\text{V}}{RI_0}\right)$$

Substitute numerical values and evaluate t:

$$t=-(0.500\,\text{M}\Omega)(2.50\,\mu\text{F})\ln\left[\frac{12.0\,\text{V}}{(0.500\,\text{M}\Omega)(96.0\,\mu\text{A})}\right]=\boxed{1.73\,\text{s}}$$

General Problems

107 •• **[SSM]** In Figure 25-75, R_1 = 4.00 Ω, R_2 = 6.00 Ω, R_3 = 12.0 Ω, and the battery emf is 12.0 V. Denote the currents through these resistors as I_1, I_2 and

I_3, respectively, (*a*) Decide which of the following inequalities holds for this circuit. Explain your answer conceptually. (1) $I_1 > I_2 > I_3$, (2) $I_2 = I_3$, (3) $I_3 > I_2$, (4) None of the above (*b*) To verify that your answer to Part (*a*) is correct, calculate all three currents.

Determine the Concept We can use Kirchhoff's rules in Part (*b*) to confirm our choices in Part (*a*).

(*a*) 1. The potential drops across R_2 and R_3 are equal, so $I_2 > I_3$. The current in R_1 equals the sum of the currents I_2 and I_3, so I_1 is greater than either I_2 or I_3.

(*b*) Apply Kirchhoff's junction rule to obtain:

$$I_1 - I_2 - I_3 = 0 \quad (1)$$

Applying Kirchhoff's loop rule in the clockwise direction to the loop defined by the two resistors in parallel yields:

$$R_3 I_3 - R_2 I_2 = 0$$

or

$$0I_1 - R_2 I_2 + R_3 I_3 = 0 \quad (2)$$

Apply Kirchhoff's loop rule in the clockwise direction to the loop around the perimeter of the circuit to obtain:

$$\mathcal{E} - R_1 I_1 - R_2 I_2 = 0$$

or

$$R_1 I_1 + R_2 I_2 - 0I_3 = \mathcal{E} \quad (3)$$

Substituting numerical values in equations (1), (2), and (3) yields:

$$I_1 - I_2 - I_3 = 0$$
$$0I_1 - (6.00\,\Omega)I_2 + (12.0\,\Omega)I_3 = 0$$
$$(4.00\,\Omega)I_1 + (6.00\,\Omega)I_2 - 0I_3 = 12.0\text{ V}$$

Solve this system of three equations in three unknowns for the currents in the branches of the circuit to obtain:

$I_1 = \boxed{1.50\text{ A}}$, $I_2 = \boxed{1.00\text{ A}}$, and $I_3 = \boxed{0.50\text{ A}}$, confirming our choice in Part (*a*).

108 •• A 120-V, 25.0-W light bulb is connected in series with a 120-V, 100-W light bulb and a potential difference of 120 V is placed across the combination. Assume the bulbs have constant resistance. (*a*) Which bulb should be brighter under these conditions? Explain your answer conceptually. *Hint: What does the phrase "25.0-W light bulb" mean? That is, under what conditions is 25-W of power delivered to the bulb?* (*b*) Determine the power delivered to each bulb under these conditions. Do your results support your answer to Part (*a*)?

Picture the Problem In Part (*b*) we need to find the current drawn by the series combination of the two light bulbs in order to calculate the actual power output of each bulb. To find this current, we first need to determine the resistances of the bulbs. These resistances are given by $R = \mathcal{E}^2/P$, one of the three forms of Equation 25-14.

(*a*) The 25-W bulb will be brighter. The more power delivered to a bulb the brighter the bulb. The resistance of the 25-W bulb is 4 times greater than that of the 100-W bulb, and in the series combination, the same current *I* flows through the bulbs. Hence, $I^2R_{25} > I^2R_{100}$.

(*b*) The actual power output of each bulb is given by:

$$P_{25} = I^2R_{25} \quad (1)$$

and

$$P_{100} = I^2R_{100} \quad (2)$$

We need to find the current drawn by the series combination of the two light bulbs. To find this current, we first need to determine the resistances of the bulbs. There resistances are given by:

$$R_{25} = \frac{\mathcal{E}^2}{P_{25}} = \frac{(120\ \text{V})^2}{25\ \text{W}} = 576\Omega$$

and

$$R_{100} = \frac{\mathcal{E}^2}{P_{100}} = \frac{(120\ \text{V})^2}{100\ \text{W}} = 144\Omega$$

Use Ohm's law to express the current drawn by the series combination of the light bulbs:

$$I = \frac{\mathcal{E}}{R_{\text{eq}}} = \frac{\mathcal{E}}{R_{25} + R_{100}}$$

Substitute numerical values and evaluate *I*:

$$I = \frac{120\ \text{V}}{576\ \Omega + 144\ \Omega} = 0.1667\ \text{A}$$

Substitute numerical values in equations (1) and (2) and evaluate P_{25} and P_{100}:

$$P_{25} = (0.1667\ \text{A})^2(576\ \Omega) = \boxed{16\ \text{W}}$$

and

$$P_{100} = (0.1667\ \text{A})^2(144\ \Omega) = \boxed{4\ \text{W}}$$

confirming our choice in Part (*a*).

109 •• The circuit shown in Figure 25-76 is a *Wheatstone bridge*, and the variable resistor is being used as a slide-wire potentiometer. The resistance R_0 is known. This "bridge" is used to determine an unknown resistance R_x. The resistances R_1 and R_2 comprise a wire 1.00 m long. Point *a* is a sliding contact that is moved along the wire to vary these resistances. Resistance R_1 is proportional to the distance from the left end of the wire (labeled 0.00 cm) to point *a*, and R_2 is proportional to the distance from point *a* to the right end of the wire (labeled

100 cm). The sum of R_1 and R_2 remains constant. When points *a* and *b* are at the same potential, there is no current in the galvanometer and the bridge is said to be balanced. (Because the galvanometer is used to detect the absence of a current, it is called a *null detector*.) If the fixed resistance $R_0 = 200\ \Omega$, find the unknown resistance R_x if (*a*) the bridge balances at the 18.0-cm mark, (*b*) the bridge balances at the 60.0-cm mark, and (*c*) the bridge balances at the 95.0-cm mark.

Picture the Problem Let the current flowing through the galvanometer be I_G. By applying Kirchhoff's rules to the loops including 1) R_1, the galvanometer, and R_x, and 2) R_2, the galvanometer, and R_0, we can obtain two equations relating the unknown resistance to R_1, R_2 and R_0. Using $R = \rho L/A$ will allow us to express R_x in terms of the length of wire L_1 that corresponds to R_1 and the length of wire L_2 that corresponds to R_2.

Apply Kirchhoff's loop rule to the loop that includes R_1, the galvanometer, and R_x to obtain:

$$-R_1I_1 + R_xI_2 = 0 \quad (1)$$

Apply Kirchhoff's loop rule to the loop that includes R_2, the galvanometer, and R_0 to obtain:

$$-R_2(I_1 - I_G) + R_0(I_2 + I_G) = 0 \quad (2)$$

When the bridge is balanced, $I_G = 0$ and equations (1) and (2) become:

$$R_1I_1 = R_xI_2 \quad (3)$$

and

$$R_2I_1 = R_0I_2 \quad (4)$$

Divide equation (3) by equation (4) and solve for R_x to obtain:

$$R_x = R_0\frac{R_1}{R_2} \quad (5)$$

Express R_1 and R_2 in terms of their lengths, cross-sectional areas, and the resistivity of their wire:

$$R_1 = \rho\frac{L_1}{A} \text{ and } R_2 = \rho\frac{L_2}{A}$$

Substitute in equation (5) to obtain:

$$R_x = R_0\frac{L_1}{L_2}$$

(*a*) When the bridge balances at the 18.0-cm mark, $L_1 = 18.0$ cm, $L_2 = 82.0$ cm and:

$$R_x = (200\,\Omega)\frac{18.0\,\text{cm}}{82.0\,\text{cm}} = \boxed{43.9\,\Omega}$$

(*b*) When the bridge balances at the 60.0-cm mark, L_1 = 60.0 cm, L_2 = 40.0 cm and:

$$R_x = (200\,\Omega)\frac{60.0\,\text{cm}}{40.0\,\text{cm}} = \boxed{300\,\Omega}$$

(*c*) When the bridge balances at the 95.0-cm mark, L_1 = 95.0 cm, L_2 = 5.0 cm and:

$$R_x = (200\,\Omega)\frac{95.0\,\text{cm}}{5.0\,\text{cm}} = \boxed{3.8\,\text{k}\Omega}$$

110 •• For the Wheatstone bridge in Problem 109, suppose the bridge balances at the 98.0-cm mark. (*a*) What is the unknown resistance? (*b*) What is the percentage error in the measured value of R_x if there is an error of 2.00 mm in the location of the balance point? (*c*) To what value should R_0 be changed to so that the balance point for this unknown resistor will be nearer the 50.0-cm mark? (*d*) If the balance point is at the 50.0-cm mark, what is the percentage error in the measured value of R_x if there is an error of 2.00 mm in the location of the balance point?

Picture the Problem Let the current flowing through the galvanometer by I_G. By applying Kirchhoff's rules to the loops including 1) R_1, the galvanometer, and R_x, and 2) R_2, the galvanometer, and R_0, we can obtain two equations relating the unknown resistance to R_1, R_2 and R_0. Using $R = \rho L/A$ will allow us to express R_x in terms of the length of wire L_1 that corresponds to R_1 and the length of wire L_2 that corresponds to R_2. To find the effect of an error of 2.00 mm in the location of the balance point we can use the relationship $\Delta R_x = (dR_x/dL)\Delta L$ to determine ΔR_x and then divide by $R_x = R_0\,L/(1-L)$ to find the fractional change (error) in R_x resulting from a given error in the determination of the balance point.

Apply Kirchhoff's loop rule to the loop that includes R_1, the galvanometer, and R_x to obtain:

$$-R_1I_1 + R_xI_2 = 0 \quad (1)$$

Apply Kirchhoff's loop rule to the loop that includes R_2, the galvanometer, and R_0 to obtain:

$$-R_2(I_1 - I_G) + R_0(I_2 + I_G) = 0 \quad (2)$$

When the bridge is balanced, $I_G = 0$ and equations (1) and (2) become:

$$R_1I_1 = R_xI_2 \quad (3)$$

and

$$R_2I_1 = R_0I_2 \quad (4)$$

Divide equation (3) by equation (4) and solve for R_x to obtain:

$$R_x = R_0\frac{R_1}{R_2} \quad (5)$$

Express R_1 and R_2 in terms of their lengths, cross-sectional areas, and the resistivity of their wire:

$$R_1 = \rho\frac{L_1}{A} \text{ and } R_2 = \rho\frac{L_2}{A}$$

Substitute in equation (5) to obtain:

$$R_x = R_0\frac{L_1}{L_2} \qquad (6)$$

(*a*) When the bridge balances at the 98.0-cm mark, $L_1 = 98.0$ cm, $L_2 = 2.0$ cm and:

$$R_x = (200\,\Omega)\frac{98.0\,\text{cm}}{2.0\,\text{cm}} = \boxed{9.8\,\text{k}\Omega}$$

(*b*) Express R_x in terms of the distance to the balance point:

$$R_x = R_0\frac{L}{1-L}$$

Express the error ΔR_x in R_x resulting from an error ΔL in L:

$$\Delta R_x = \frac{dR_x}{dL}\Delta L = R_0\frac{d}{dL}\left[\frac{L}{1-L}\right]\Delta L$$

$$= R_0\frac{1}{(1-L)^2}\Delta L$$

Divide ΔR_x by R_x to obtain:

$$\frac{\Delta R_x}{R_x} = \frac{R_0\dfrac{1}{(1-L)^2}\Delta L}{R_0\dfrac{L}{1-L}} = \frac{1}{1-L}\frac{\Delta L}{L}$$

Evaluate $\Delta R_x/R_x$ for $L = 98.0$ cm and $\Delta L = 2.00$ mm:

$$\frac{\Delta R_x}{R_x} = \left(\frac{1.00\,\text{m}}{1.00\,\text{m} - 0.98\,\text{m}}\right)\left(\frac{2.00\,\text{mm}}{1.00\,\text{m}}\right)$$

$$= \boxed{10\%}$$

(*c*) Solve equation (6) for the ratio of L_1 to L_2:

$$\frac{L_1}{L_2} = \frac{R_x}{R_0}$$

For $L_1 = 50.0$ cm, $L_2 = 50.0$ cm, $R_0 = R_x = 9.8$ kΩ. Hence, a resistor of approximately 10 kΩ will cause the bridge to balance near the 50.0-cm mark.

(*d*) From Part (*b*) we have:

$$\frac{\Delta R_x}{R_x} = \frac{1}{1-L}\frac{\Delta L}{L}$$

Evaluate $\Delta R_x/R_x$ for L = 50.0 cm and ΔL = 2.00 mm:

$$\frac{\Delta R_x}{R_x}=\left(\frac{1.00\,\text{m}}{1.00\,\text{m}-0.50\,\text{m}}\right)\left(\frac{2.00\,\text{mm}}{1.00\,\text{m}}\right)=\boxed{0.40\%}$$

111 •• **[SSM]** You are running an experiment that uses an accelerator that produces a 3.50-μA proton beam. Each proton in the beam has 60.0-MeV of kinetic energy. The protons impinge upon, and come to rest inside, a 50.0-g copper target within a vacuum chamber. You are concerned that the target will get too hot and melt the solder on some connecting wires that are crucial to the experiment. (*a*) Determine the number of protons that strike the target per second. (*b*) Find the amount of energy delivered to the target each second. (*c*) Determine how much time elapses before the target temperature increases to 300°C? (Neglect any heat released by the target.)

Picture the Problem Knowing the beam current and charge per proton, we can use $I = ne$ to determine the number of protons striking the target per second. The energy deposited per second is the power delivered to the target and is given by $P = IV$. We can find the elapsed time before the target temperature rises 300°C using $\Delta Q = P\Delta t = mc_{\text{Cu}}\Delta T$.

(*a*) Relate the current to the number of protons per second n arriving at the target:

$$I = ne \Rightarrow n=\frac{I}{e}$$

Substitute numerical values and evaluate n:

$$n=\frac{3.50\,\mu\text{A}}{1.602\times10^{-19}\,\text{C}}=\boxed{2.18\times10^{13}\,\text{s}^{-1}}$$

(*b*) Express the power of the beam in terms of the beam current and energy:

$$P = IV = (3.50\,\mu\text{A})\left(60.0\frac{\text{MeV}}{\text{proton}}\right)=\boxed{210\text{ W}}$$

(*c*) Relate the energy delivered to the target to its heat capacity and temperature change:

$$\Delta Q = P\Delta t = C_{\text{Cu}}\Delta T = mc_{\text{Cu}}\Delta T$$

Solving for Δt yields:

$$\Delta t=\frac{mc_{\text{Cu}}\Delta T}{P}$$

Substitute numerical values (see Table 19-1 for the specific heat of copper)and evaluate Δt:

$$\Delta t = \frac{(50.0\,\text{g})(0.386\,\text{kJ/kg}\cdot\text{K})(300°\text{C})}{210\,\text{J/s}} = \boxed{27.6\,\text{s}}$$

112 •• The belt of a Van de Graaff generator carries a surface charge density of 5.00 mC/m^2. The belt is 0.500 m wide and moves at 20.0 m/s. (*a*) What current does the belt carry? (*b*) If the potential of the dome of the generator is 100 kV above ground, what is the minimum power of the motor needed to drive the belt?

Picture the Problem We can use the definition of current to express the current delivered by the belt in terms of the surface charge density, width, and speed of the belt. The minimum power needed to drive the belt can be found from $P = IV$.

(*a*) Use its definition to express the current carried by the belt:

$$I = \frac{dQ}{dt} = \sigma w \frac{dx}{dt} = \sigma w v$$

Substitute numerical values and evaluate I:

$$I = (5.00\,\text{mC/m}^2)(0.500\,\text{m})(20.0\,\text{m/s}) = \boxed{50.0\,\text{mA}}$$

(*b*) Express the minimum power of the motor in terms of the current delivered and the potential of the charge:

$$P = IV$$

Substitute numerical values and evaluate P:

$$P = (50.0\,\text{mA})(100\,\text{kV}) = \boxed{5.00\,\text{kW}}$$

113 •• Large conventional electromagnets use water cooling to prevent excessive heating of the magnet coils. A large laboratory electromagnet carries a current equal to 100 A when a voltage of 240 V is applied to the terminals of the energizing coils. To cool the coils, water at an initial temperature of 15°C is circulated around the coils. How many liters of water must circulate by the coils each second if the temperature of the coils is not to exceed 50°C?

Picture the Problem We can differentiate the expression relating the amount of heat required to produce a given temperature change with respect to time to express the mass flow-rate required to maintain the temperature of the coils at 50°C. We can then use the definition of density to find the necessary volume flow rate.

Express the heat that must be dissipated in terms of the specific heat and mass of the water and the desired temperature change of the water:

$$Q = mc_{\text{water}}\Delta T$$

Differentiate this expression with respect to time to obtain an expression for the power dissipation:

$$P = \frac{dQ}{dt} = \frac{dm}{dt}c_{\text{water}}\Delta T$$

Solving for $\frac{dm}{dt}$ yields:

$$\frac{dm}{dt} = \frac{P}{c_{\text{water}}\Delta T}$$

Substitute for the power dissipated to obtain:

$$\frac{dm}{dt} = \frac{IV}{c_{\text{water}}\Delta T}$$

Substitute numerical values and evaluate $\frac{dm}{dt}$:

$$\frac{dm}{dt} = \frac{(100\,\text{A})(240\,\text{V})}{\left(4.18\frac{\text{kJ}}{\text{kg}\cdot\text{K}}\right)(50°\text{C} - 15°\text{C})} = 0.164\,\text{kg/s}$$

Using the definition of density, express the volume flow rate in terms of the mass flow rate to obtain:

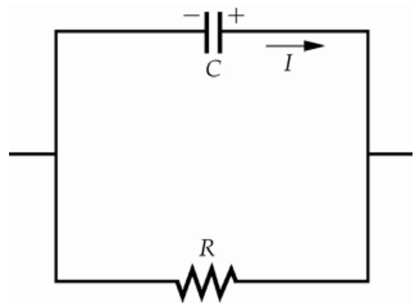
$$\frac{dV}{dt} = \frac{1}{\rho}\frac{dm}{dt}$$

Substitute numerical values and evaluate $\frac{dV}{dt}$:

$$\frac{dV}{dt} = \left(\frac{0.164\frac{\text{kg}}{\text{s}}}{1.00\times10^{3}\,\frac{\text{kg}}{\text{m}^3}}\right)\left(\frac{1\,\text{L}}{10^{-3}\,\text{m}^3}\right) = \boxed{0.16\,\text{L/s}}$$

114 ••• (*a*) Give support to the assertion that a leaky capacitor (one for which the resistance of the dielectric is finite) can be modeled as a capacitor that has an infinite resistance in parallel with a resistor. (*b*) Show that the time constant for discharging this capacitor is given by $\tau = \kappa\epsilon_0\rho$. (For simplicity, assume the capacitor is a parallel plate variety filled completely with a leaky dielectric.) (*c*) Mica has a dielectric constant equal to about 5.0 and a resistivity equal to about 9.0×10^{13} Ω·m. Calculate the time it takes for the charge of a mica-filled capacitor to decrease to 10 percent of its initial value.

Picture the Problem We'll assume that the capacitor is fully charged initially and apply Kirchhoff's loop rule to the circuit fragment to obtain the differential equation describing the discharge of the leaky capacitor. We'll show that the solution to this equation is the familiar expression for an exponential decay with time constant $\tau = \epsilon_0 \rho\kappa$.



(*a*) If we think of the leaky capacitor as a resistor/capacitor combination, the voltage drop across the resistor must be the same as the voltage drop across the capacitor. Hence they must be in parallel.

(*b*) Assuming that the capacitor is initially fully charged, apply Kirchhoff's loop rule to the circuit fragment to obtain:

$$\frac{Q}{C} - RI = 0$$

or, because $I = -\frac{dQ}{dt}$,

$$\frac{Q}{C} + R\frac{dQ}{dt} = 0$$

Separate variables in this differential equation to obtain:

$$\frac{dQ}{Q} = -\frac{1}{RC}dt \qquad (1)$$

The capacitance of a dielectric-filled parallel-plate capacitor with plate area A and plate separation d is given by:

$$C = \frac{\kappa \epsilon_0 A}{d}$$

The resistance of a conductor with the same dimensions is given by:

$$R = \frac{\rho d}{A}$$

The product of R and C is:

$$RC = \epsilon_0 \rho\kappa$$

Substituting for RC in the differential equation yields:

$$\frac{dQ}{Q} = -\frac{1}{\epsilon_0 \rho\kappa}dt$$

Integrate this equation from $Q' = Q_0$ to Q to obtain:

$$Q = Q_0 e^{-t/\tau} \text{ where } \tau = \boxed{\epsilon_0 \rho\kappa}$$

(*c*) Because $Q/Q_0 = 0.10$:

$$e^{-t/\tau} = 0.10$$

Solve for t by taking the natural logarithm of both sides of the equation:

$$-\frac{t}{\tau}=\ln(0.10)\Rightarrow t=-\epsilon_0\ \rho\kappa\ln(0.10)$$

Substitute numerical values and evaluate t:

$$t=-\left(8.854\times10^{-12}\ \frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(9.0\times10^{13}\ \Omega\cdot\text{m}\right)(5)\ln(0.10)=9.17\times10^3\ \text{s}\approx\boxed{2.5\,\text{h}}$$

115 ••• Figure 25-77 shows the basis of the sweep circuit used in an oscilloscope. Switch S is an electronic switch that closes whenever the potential across the switch *S* increases to a value V_c and opens when the potential across switch S decreases to 0.200 V. The emf $\mathcal{E}$], which is much greater than V_c, charges the capacitor C through a resistor R_1. The resistor R_2 represents the small but finite resistance of the electronic switch. In a typical circuit, $\mathcal{E}$ = 800 V, V_c = 4.20 V, R_2 = 1.00 mΩ, R_1 = 0.500 MΩ, and C = 20.0 nF. (*a*) What is the time constant for charging of the capacitor C? (*b*) Show that as the potential across switch S increases from 0.200 V to 4.20 V, the potential across the capacitor increases almost linearly with time. *Hint*: *Use the approximation* $e^x \approx 1 + x$, for $|x| << 1$. *(This approximation of* e^x *can be derived using the differential approximation.)* (*c*) What should the value of R_1 be changed to so that the capacitor charges from 0.200 V to 4.20 V in 0.100 s? (*d*) How much time elapses during the discharge of the capacitor when switch S closes? (*e*) At what average rate is energy dissipated in the resistor R_1 during charging and in the switch resistance R_2 during discharge?

Picture the Problem We can use its definition to find the time constant of the charging circuit in Part (*a*). In Part (*b*) we can use the expression for the potential difference as a function of time across a charging capacitor and utilize the hint given in the problem statement to show that the voltage across the capacitor increases almost linearly over the time required to bring the potential across the switch to its critical value. In Part (*c*) we can use the result derived in Part (*b*) to find the value of R_1 such that C charges from 0.200 V to 4.20 V in 0.100 s. In Part (*d*) we can use the expression for the potential difference as a function of time across a discharging capacitor to find the discharge time. Finally, in Part (*e*) we can integrate I^2R_1 over the discharge time to find the rate at which energy is dissipated in R_1 during the discharge of the capacitor and use the difference in the energy stored in the capacitor initially and when the switch opens to find the rate of energy dissipation in resistance of the capacitor.

(a) When the capacitor is charging, the switch is open and the resistance in the charging circuit is R_1. Hence:

$$\tau = R_1 C = (0.500\,\text{M}\Omega)(20.0\,\text{nF}) = \boxed{10.0\,\text{ms}}$$

(b) Express the voltage across the charging capacitor as a function of time:

$$V(t) = \mathcal{E}\left(1 - e^{-t/\tau}\right)$$

Use the power series for e^x to expand $e^{t/\tau}$:

$$e^{t/\tau} = 1 + \frac{t}{\tau} + \frac{1}{2!}\left(\frac{t}{\tau}\right)^2 + \ldots \approx 1 + \frac{1}{\tau}t$$

provided $t/\tau << 1$.

Substitute for $e^{t/\tau}$ to obtain:

$$V(t) = \mathcal{E}\left\{1 - \left(1 + \frac{1}{\tau}t\right)\right\} = \boxed{\frac{\mathcal{E}}{\tau}t}$$

(c) Using the result derived in (b), relate the time Δt required to change the voltage across the capacitor by an amount ΔV to $\Delta V(t)$:

$$\Delta V(t) = \frac{\mathcal{E}}{\tau}\Delta t$$

or

$$\tau = R_1 C = \frac{\mathcal{E}}{\Delta V(t)}\Delta t \Rightarrow R_1 = \frac{\mathcal{E}}{C\Delta V(t)}\Delta t$$

Substitute numerical values and evaluate R_1:

$$R_1 = \frac{(800\,\text{V})(0.100\,\text{s})}{(20.0\,\text{nF})(4.20\,\text{V} - 0.200\,\text{V})} = \boxed{1.00\,\text{G}\Omega}$$

(d) Express the potential difference across the capacitor as a function of time:

$$V_\text{C}(t) = V_\text{C0}e^{-t/\tau'}$$

where

$\tau' = R_2C$.

Solve for t to obtain:

$$t = -\tau' \ln\left(\frac{V_\text{C}(t)}{V_\text{C0}}\right) = -R_2 C \ln\left(\frac{V_\text{C}(t)}{V_\text{C0}}\right)$$

Substitute numerical values and evaluate t:

$$t = -(1.00\,\text{m}\Omega)(20.0\,\text{nF})\ln\left(\frac{0.200\,\text{V}}{4.20\,\text{V}}\right) = 60.89\,\text{ps} = \boxed{60.9\,\text{ps}}$$

(*e*) Express the rate at which energy is dissipated in R_1 as a function of its resistance and the current through it:

$$P_1 = \frac{\Delta E_1}{\Delta t} = I^2 R_1$$

Because the current varies with time, we need to integrate over time to find ΔE_1:

$$\Delta E_1 = \int_{t_1}^{t_2} I^2 R_1 dt = \int_{t_1}^{t_2} \left(\frac{V(t)}{R_1}\right)^2 R_1 dt$$

$$= \int_{t_1}^{t_2} \left(\frac{\mathcal{E}t}{\tau R_1}\right)^2 R_1 dt$$

$$= \left(\frac{\mathcal{E}}{\tau}\right)^2 \frac{1}{R_1} \int_{0.005\text{ s}}^{0.105\text{ s}} t^2 dt$$

$$= \left(\frac{800\,\text{V}}{20.0\,\text{s}}\right)^2 \frac{1}{1.00\,\text{G}\Omega} \left[\frac{t^3}{3}\right]_{0.00500\text{ s}}^{0.105\text{ s}}$$

$$= 6.17\times10^{-10}\text{ J}$$

Substitute numerical values and evaluate P_1:

$$P_1 = \frac{6.17\times10^{-10}\text{ J}}{0.100\,\text{s}} = \boxed{6.17\,\text{nW}}$$

Express the rate at which energy is dissipated in the switch resistance:

$$P_2 = \frac{\Delta U_\text{C}}{\Delta t} = \frac{U_\text{Ci} - U_\text{Cf}}{\Delta t}$$

$$= \frac{\frac{1}{2}CV_\text{i}^2 - \frac{1}{2}CV_\text{f}^2}{\Delta t} = \frac{\frac{1}{2}C\left(V_\text{i}^2 - V_\text{f}^2\right)}{\Delta t}$$

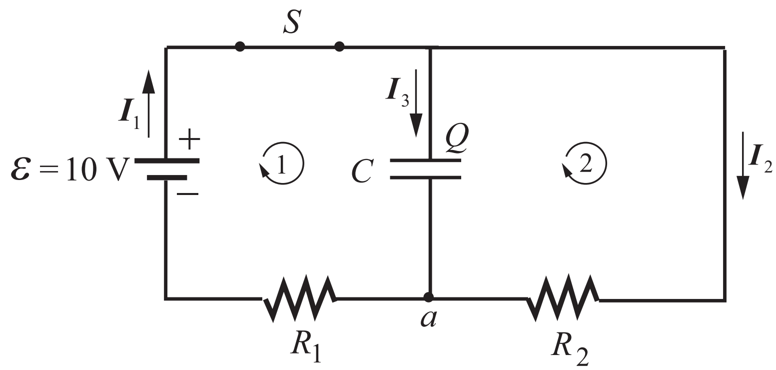
Substitute numerical values and evaluate P_2:

$$P_2 = \frac{\frac{1}{2}(20.0\,\text{nF})\left[(4.20\,\text{V})^2 - (0.200\,\text{V})^2\right]}{60.89\,\text{ps}} = \boxed{2.89\,\text{kW}}$$

116 ••• In the circuit shown in Figure 25-78, $R_1 = 2.00$ MΩ, $R_2 = 5.00$ MΩ, and $C = 1.00$ μF. The capacitor is initially without charge on either plate. At $t = 0$, switch S is closed, and at $t = 2.00$ s switch S is opened. (*a*) Sketch a graph of the voltage across C and the current in R_2 between $t = 0$ and $t = 10.0$ s. (*b*) Find the voltage across the capacitor at $t = 2.00$ s and at $t = 8.00$ s.

Picture the Problem We can apply both the loop and junction rules to obtain equations that we can use to obtain a linear differential equation with constant coefficients describing the current in R_2 as a function of time. We can solve this differential equation by assuming a solution of an appropriate form, differentiating this assumed solution and substituting it and its derivative in the differential equation. Equating coefficients, requiring the solution to hold for all

values of the assumed constants, and invoking an initial condition will allow us to find the constants in the assumed solution. Once we know how the current varies with time in R_2, we can express the potential difference across it (as well as across C because they are in parallel). To find the voltage across the capacitor at $t = 8.00$ s, we can express the dependence of the voltage on time for a discharging capacitor (C is discharging after $t = 2.00$ s) and evaluate this function, with a time constant differing from that found in (a), at $t = 6.00$ s. The diagram shows the circuit shortly after the switch is closed. The directions of the currents in the resistors and the capacitor have been chosen as shown.



(a) Apply the junction rule at junction a to obtain:

$$I_1 = I_2 + I_3 \quad (1)$$

Apply the loop rule to loop 1 to obtain:

$$\mathcal{E} - \frac{Q}{C} - R_1 I_1 = 0 \quad (2)$$

Apply the loop rule to loop 2 to obtain:

$$\frac{Q}{C} - R_2 I_2 = 0 \quad (3)$$

Differentiate equation (2) with respect to time to obtain:

$$\frac{d}{dt}\left[\mathcal{E} - R_1 I_1 - \frac{Q}{C}\right] = 0 - R_1\frac{dI_1}{dt} - \frac{1}{C}\frac{dQ}{dt}$$

$$= -R_1\frac{dI_1}{dt} - \frac{1}{C}I_3 = 0$$

or

$$R_1\frac{dI_1}{dt} = -\frac{1}{C}I_3 \quad (4)$$

Differentiate equation (3) with respect to time to obtain:

$$\frac{d}{dt}\left[\frac{Q}{C} - R_2 I_2\right] = \frac{1}{C}\frac{dQ}{dt} - R_2\frac{dI_2}{dt} = 0$$

or

$$R_2\frac{dI_2}{dt} = \frac{1}{C}I_3 \quad (5)$$

Using equation (1), substitute for I_3 in equation (5) to obtain:

$$\frac{dI_2}{dt}=\frac{1}{R_2C}\left(I_1-I_2\right) \qquad (6)$$

Solve equation (2) for I_1:

$$I_1=\frac{\mathcal{E}-Q/C}{R_1}=\frac{\mathcal{E}-R_2I_2}{R_1}$$

Substitute for I_1 in equation (6) and simplify to obtain the differential equation for I_2:

$$\frac{dI_2}{dt}=\frac{1}{R_2C}\left(\frac{\mathcal{E}-R_2I_2}{R_1}-I_2\right)=\frac{\mathcal{E}}{R_1R_2C}-\left(\frac{R_1+R_2}{R_1R_2C}\right)I_2$$

To solve this linear differential equation with constant coefficients we can assume a solution of the form:

$$I_2(t)=a+be^{-t/\tau} \qquad (7)$$

Differentiate $I_2(t)$ with respect to time to obtain:

$$\frac{dI_2}{dt}=\frac{d}{dt}\left[a+be^{-t/\tau}\right]=-\frac{b}{\tau}e^{-t/\tau}$$

Substitute for I_2 and dI_2/dt to obtain:

$$-\frac{b}{\tau}e^{-t/\tau}=\frac{\mathcal{E}}{R_1R_2C}-\left(\frac{R_1+R_2}{R_1R_2C}\right)\left(a+be^{-t/\tau}\right)$$

Equate coefficients of $e^{-t/\tau}$ to obtain:

$$\tau=\frac{R_1R_2C}{R_1+R_2}$$

Requiring the equation to hold for all values of a yields:

$$a=\frac{\mathcal{E}}{R_1+R_2}$$

If I_2 is to be zero when $t = 0$:

$$0=a+b\Rightarrow b=-a=-\frac{\mathcal{E}}{R_1+R_2}$$

Substitute in equation (7) to obtain:

$$I_2(t)=\frac{\mathcal{E}}{R_1+R_2}-\frac{\mathcal{E}}{R_1+R_2}e^{-t/\tau}=\frac{\mathcal{E}}{R_1+R_2}\left(1-e^{-t/\tau}\right)$$

where $\tau=\dfrac{R_1R_2C}{R_1+R_2}$

Substitute numerical values and evaluate τ:

$$\tau = \frac{(2.00\,\mathrm{M\Omega})(5.00\,\mathrm{M\Omega})(1.00\,\mu\mathrm{F})}{2.00\,\mathrm{M\Omega}+5.00\,\mathrm{M\Omega}} = 1.43\,\mathrm{s}$$

Substitute numerical values and evaluate $I_2(t)$:-

$$I_2(t) = \frac{10.0\,\mathrm{V}}{2.00\,\mathrm{M\Omega}+5.00\,\mathrm{M\Omega}}\left(1-e^{-t/1.429\,\mathrm{s}}\right) = (1.429\,\mu\mathrm{A})\left(1-e^{-t/1.43\,\mathrm{s}}\right)$$

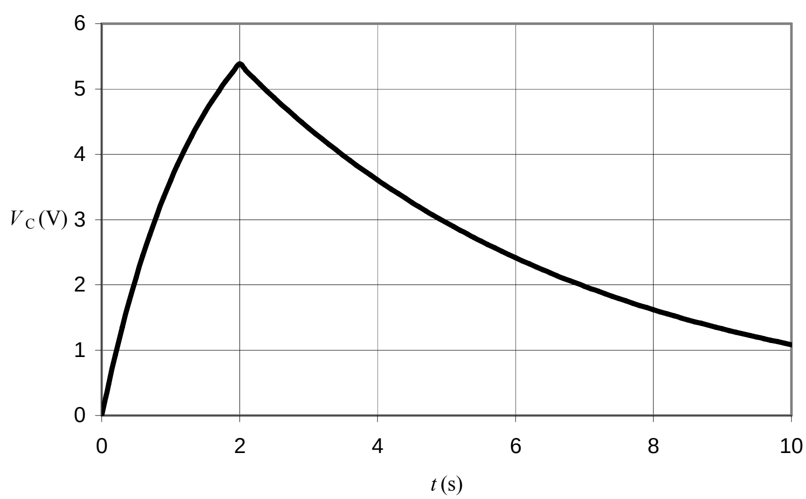
Because C and R_2 are in parallel, they have a common potential difference given by:

$$V_C(t) = V_2(t) = I_2(t)R_2 = (1.429\,\mu\mathrm{A})(5.00\,\mathrm{M\Omega})\left(1-e^{-t/1.429\mathrm{s}}\right) = (7.143\,\mathrm{V})\left(1-e^{-t/1.429\mathrm{s}}\right)$$

Evaluate V_C at $t = 2.00$ s:

$$V_C(2\,\mathrm{s}) = (7.143\,\mathrm{V})\left(1-e^{-2.00\,\mathrm{s}/1.429\,\mathrm{s}}\right) = 5.381\,\mathrm{V}$$

The voltage across the capacitor as a function of time is shown in the following graph. The current through the 5.00-MΩ resistor R_2 follows the same time course, its value being $V_C/(5.00\times10^6)$ A.



(b) The value of V_C at $t = 2.00$ s has already been determined to be:

$$V_C(2.00\,\mathrm{s}) = 5.381\,\mathrm{V} = \boxed{5.38\,\mathrm{V}}$$

When S is opened at $t = 2.00$ s, C discharges through R_2 with a time constant given by:

$$\tau' = R_2C = (5.00\,\mathrm{M\Omega})(1.00\,\mu\mathrm{F}) = 5.00\,\mathrm{s}$$

Express the potential difference across C as a function of time:

$$V_C(t) = V_{C0}e^{-(t-2.00\,\text{s})/\tau'} = (5.381\,\text{V})e^{-(t-2.00\,\text{s})/5.00\,\text{s}}$$

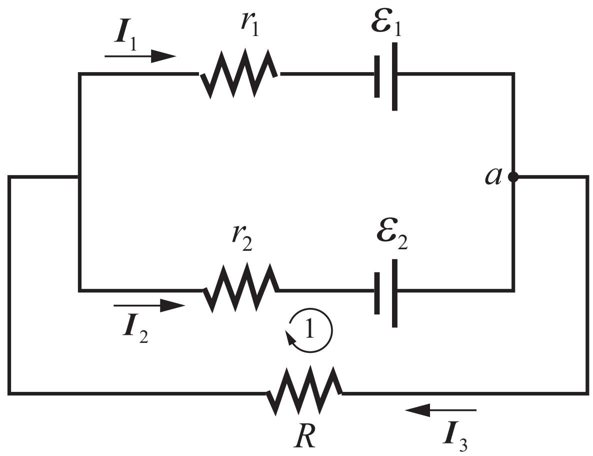
Evaluate V_C at t = 8.00 s to obtain:

$$V_C(8.00\,\text{s}) = (5.381\,\text{V})e^{-6.00\,\text{s}/5.00\,\text{s}} = \boxed{1.62\,\text{V}}$$

in good agreement with the graph.

117 ••• Two batteries that have emfs $\mathcal{E}_1$ and $\mathcal{E}_2$ and internal resistances r_1 and r_2 are connected in parallel. Prove that if a resistor of resistance R is connected in parallel with combination, the optimal load resistance (the value of R at which maximum power is delivered) is given by $R = r_1r_2/(r_1 + r_2)$.

Picture the Problem Let I_1 be the current supplied by the battery whose emf is $\mathcal{E}_1$, I_2 the current supplied by the battery whose emf is $\mathcal{E}_2$, and I_3 the current through the resistor R. We can apply Kirchhoff's rules to obtain three equations in the unknowns I_1, I_2, and I_3 that we can solve simultaneously to find I_3. We can then express the power delivered by the sources to R. Setting the derivative of this expression equal to zero will allow us to solve for the value of R that maximizes the power delivered by the sources.



Apply Kirchhoff's junction rule at a to obtain:

$$I_1 + I_2 = I_3 \tag{1}$$

Apply the loop rule around the outside of the circuit to obtain:

$$\mathcal{E}_1 - I_3R - r_1I_1 = 0 \tag{2}$$

Apply the loop rule to loop 1 to obtain:

$$\mathcal{E}_2 - I_3R - r_2I_2 = 0 \tag{3}$$

Eliminate I_1 from equations (1) and (2) to obtain:

$$\mathcal{E}_1 - I_3 R - r_1 (I_3 - I_2) = 0 \qquad (4)$$

Solving equation (3) for I_2 yields:

$$I_2 = \frac{\mathcal{E}_2 - I_3 R}{r_2}$$

Substitute for I_2 in equation (4) to obtain:

$$\mathcal{E}_1 - I_3 R - r_1\left(I_3 - \frac{\mathcal{E}_2 - I_3 R}{r_2}\right) = 0$$

Solving for I_3 yields:

$$I_3 = \frac{\mathcal{E}_1 r_2 + \mathcal{E}_2 r_1}{r_1 r_2 + R(r_1 + r_2)}$$

Express the power delivered to R:

$$P = I_3^2 R = \left(\frac{\mathcal{E}_1 r_2 + \mathcal{E}_2 r_1}{r_1 r_2 + R(r_1 + r_2)}\right)^2 R$$

$$= \left(\frac{\mathcal{E}_1 r_2 + \mathcal{E}_2 r_1}{r_1 + r_2}\right)^2 \left[\frac{R}{(R + A)^2}\right]$$

where $A = \dfrac{r_1 r_2}{r_1 + r_2}$

Noting that the quantity in parentheses is independent of R and that therefore we can ignore it, differentiate P with respect to R and set the derivative equal to zero:

$$\frac{dP}{dR} = \frac{d}{dR}\left[\frac{R}{(R + A)^2}\right]$$

$$= \frac{(R + A)^2 - R\dfrac{d}{dR}(R + A)^2}{(R + A)^4}$$

$$= \frac{(R + A)^2 - 2R(R + A)}{(R + A)^4}$$

$$= 0 \text{ for extrema}$$

Solving for R yields:

$$R = A = \frac{r_1 r_2}{r_1 + r_2}$$

To establish that this value for R corresponds to a maximum, we need to evaluate the second derivative of P with respect to R at $R = A$ and show that this quantity is negative; that is, concave downward:

$$\frac{d^2P}{dR^2} = \frac{d}{dR}\left[\frac{(R+A)^2 - 2R(R+A)}{(R+A)^4}\right] = \frac{2R-4A}{(R+A)^4}$$

and

$$\left.\frac{d^2P}{dR^2}\right|_{R=A} = \frac{-2A}{(R+A)^4} < 0$$

Because $\left.\frac{d^2P}{dR^2}\right|_{R=A} < 0$ we can conclude that:

$R = \boxed{\frac{r_1r_2}{r_1+r_2}}$ maximizes the power delivered by the sources.

118 ••• Capacitors C_1 and C_2 are connected to a resistor of resistance R and an ideal battery that has terminal voltage V_0 as shown in Figure 25-79. Initially the throw of switch S is at contact a and both capacitors are without charge. The throw is then rotated to contact b and left there for a long time. Finally, at time $t = 0$, the throw is returned to contact a. (*a*) Quantitatively compare the total energy stored in the two capacitors at $t = 0$ and a long time later. (*b*) Find the current through R as a function of time. (*c*) Find the energy dissipated in the resistor as a function of time. (*d*) Find the total energy dissipated in the resistor and compare it with the loss of stored energy found in Part (*a*).

Picture the Problem (*a*) Let Q_1 and Q_2 represent the final charges on the capacitors C_1 and C_2. Knowing that charge is conserved as it is redistributed to the two capacitors and that the final-state potential differences across the two capacitors will be the same, we can obtain two equations in the unknowns Q_1 and Q_2 that we can solve simultaneously. We can compare the initial and final energies stored in this system by examining their ratio. (*b*) Let q_1 and q_2 be the time-dependent charges on the two capacitors after the switches are closed. We can use Kirchhoff's loop rule and the conservation of charge to obtain a first-order linear differential equation describing the current I_2 through R after the switches are closed. We can solve this differential equation by assuming a solution of the form $q_2(t) = a + be^{-t/\tau}$ and requiring that the solution satisfy the initial condition $q_2(0) = 0$ and the differential equation be satisfied for all values of t. (*c*) Once we know I_2, we can find the energy dissipated in the resistor as a function of time and (*d*) the total energy dissipated in the resistor.

(*a*) The initial and final energies stored in the capacitors are:

$$U_i = \frac{1}{2}C_1V_0^2 \qquad (1)$$

and

$$U_f = \frac{1}{2}\frac{Q_1^2}{C_1} + \frac{1}{2}\frac{Q_2^2}{C_2} \qquad (2)$$

Relate the total charge stored initially to the final charges Q_1 and Q_2 on C_1 and C_2:

$$Q = C_1V_0 = Q_1 + Q_2 \qquad (3)$$

Because, in their final state, the potential differences across the two capacitors will be the same:

$$\frac{Q_1}{C_1} = \frac{Q_2}{C_2} \qquad (4)$$

Solve equation (4) for Q_1 and substitute in equation (3) to obtain:

$$\frac{C_1}{C_2}Q_2 + Q_2 = C_1V_0 \Rightarrow Q_2 = \frac{C_1C_2}{C_1 + C_2}V_0$$

Substitute for Q_2 in either equation (3) or equation (4) and solve for Q_1 to obtain:

$$Q_1 = \frac{C_1^2}{C_1 + C_2}V_0$$

Substitute for Q_1 and Q_2 in equation (2) and simplify to obtain:

$$U_f = \frac{1}{2}\frac{\left(\frac{C_1^2}{C_1 + C_2}V_0\right)^2}{C_1} + \frac{1}{2}\frac{\left(\frac{C_1C_2}{C_1 + C_2}V_0\right)^2}{C_2} = \frac{1}{2}\frac{C_1^2}{C_1 + C_2}V_0^2$$

Expressing the difference between U_i and U_f yields:

$$U_i - U_f = \frac{1}{2}C_1V_0^2 - \frac{1}{2}\frac{C_1^2}{C_1 + C_2}V_0^2 = \boxed{\frac{1}{2}\frac{C_1C_2}{C_1 + C_2}V_0^2}$$

Note that, if we express the ratio of U_i and U_f we obtain:

$$\frac{U_i}{U_f}=\frac{C_1V_0^2}{\dfrac{\left(\dfrac{C_1^2}{C_1+C_2}V_0\right)^2}{C_1}+\dfrac{\left(\dfrac{C_1C_2}{C_1+C_2}V_0\right)^2}{C_2}}$$

$$=1+\frac{C_2}{C_1}$$

That is, U_i is greater than U_f by a factor of $1 + C_2/C_1$.

(b) Apply Kirchhoff's loop rule to the circuit when the switch is in position a to obtain:

$$\frac{q_1}{C_1}-IR-\frac{q_2}{C_2}=0$$

or, because $I=\dfrac{dq_2}{dt}$,

$$\frac{q_1}{C_1}-R\frac{dq_2}{dt}-\frac{q_2}{C_2}=0$$

Apply conservation of charge during the redistribution of charge to obtain:

$$q_1=Q-q_2=C_1V_0-q_2$$

Substituting for q_1 yields:

$$V_0-\frac{q_2}{C_1}-R\frac{dq_2}{dt}-\frac{q_2}{C_2}=0$$

Rearrange to obtain a first- order differential equation:

$$R\frac{dq_2}{dt}+\left(\frac{C_1+C_2}{C_1C_2}\right)q_2=V_0$$

Assume a solution of the form:

$$q_2(t)=a+be^{-t/\tau} \qquad (4)$$

Differentiate the assumed solution with respect to time to obtain:

$$\frac{dq_2(t)}{dt}=\frac{d}{dt}\left[a+be^{-t/\tau}\right]=-\frac{b}{\tau}e^{-t/\tau}$$

Substitute for dq_2/dt and q_2 in the differential equation to obtain:

$$R\left(-\frac{b}{\tau}e^{-t/\tau}\right)+\left(\frac{C_1+C_2}{C_1C_2}\right)\left(a+be^{-t/\tau}\right)=V_0$$

Rearranging yields:

$$\left[-\frac{R}{\tau}e^{-t/\tau}\right]b+\left(\frac{C_1+C_2}{C_1C_2}\right)a+\left[\left(\frac{C_1+C_2}{C_1C_2}\right)e^{-t/\tau}\right]b=V_0$$

If this equation is to be satisfied for all values of t:

$$a=\frac{C_1C_2}{C_1+C_2}V_0=C_{\text{eq}}V_0$$

and

$$\left[-\frac{R}{\tau}e^{-t/\tau}\right]b+\left[\left(\frac{C_1+C_2}{C_1C_2}\right)e^{-t/\tau}\right]b=0$$

Simplifying further yields:

$$-\frac{R}{\tau}+\frac{C_1+C_2}{C_1C_2}=0$$

Solve for τ to obtain:

$$\tau=R\frac{C_1C_2}{C_1+C_2}=RC_{\text{eq}}$$

Applying the initial condition $q_2(0)=0$ to equation (4) yields:

$$0=a+b$$

or

$$b=-a=-C_{\text{eq}}V_0$$

Substitute for a and b in equation (4) to obtain:

$$q_2(t)=C_{\text{eq}}V_0-C_{\text{eq}}V_0\,e^{-t/\tau}=C_{\text{eq}}V_0\left(1-e^{-t/\tau}\right)$$

Differentiate $q_2(t)$ with respect to time to find the current through R as a function of time:

$$I(t)=\frac{dq_2(t)}{dt}=C_{\text{eq}}V_0\frac{d}{dt}\left(1-e^{-t/\tau}\right)=C_{\text{eq}}V_0\left(-e^{-t/\tau}\right)\left(-\frac{1}{\tau}\right)=\frac{C_{\text{eq}}V_0}{\tau}e^{-t/\tau}=\boxed{\frac{V_0}{R}e^{-t/\tau}}$$

where $\tau=\boxed{R\frac{C_1C_2}{C_1+C_2}}$.

(*c*) Express the energy dissipated in the resistor as a function of time:

$$P(t)=I^2R=\left(\frac{V_0}{R}e^{-t/\tau}\right)^2R=\boxed{\frac{V_0^2}{R}e^{-2t/\tau}}$$

where $\tau=\boxed{R\frac{C_1C_2}{C_1+C_2}}$

(*d*) The total energy dissipated in the resistor is the integral of $P(t)$ between $t = 0$ and $t = \infty$:

$$E = \frac{V_0^2}{R}\int_0^\infty e^{-2t/RC_{\text{eq}}}\,dt = \tfrac{1}{2}V_0^2 C_{\text{eq}}$$

Because the capacitors are in series:

$$C_{\text{eq}} = \frac{C_1 C_2}{C_1 + C_2}$$

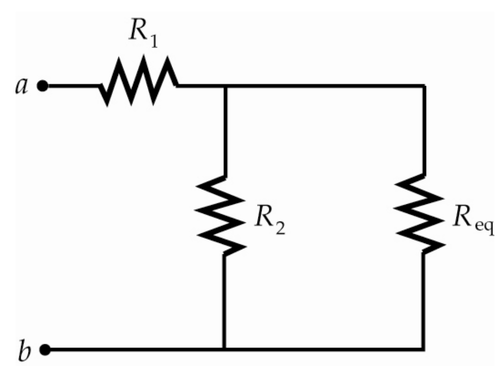
Substituting for C_{eq} yields:

$$E = \boxed{\frac{1}{2}\frac{C_1 C_2}{C_1 + C_2}V_0^2}$$

This energy, dissipated as Joule heating in the resistor, is exactly the difference between the initial and final energies found in Part (*a*).

119 ••• (*a*) Calculate the equivalent resistance (in terms of R, the resistance of each individual resistor) between points *a* and *b* for the infinite ladder of resistors shown in Figure 25-80 assuming the resistors are identical. That is assuming $R = R_1 + R_2$. (*b*) Repeat Part (*a*) but do not assume that $R_1 = R_2$ and express your answer in terms of R_1 and R_2. (*c*), Check your results by showing that your result from Part (*b*) agrees with your result from Part (*a*) if you substitute R for both R_1 and R_2.

Picture the Problem Let R be the resistance of each resistor in the ladder and let R_{eq} be the equivalent resistance of the infinite ladder. If the resistance is finite and non-zero, then adding one or more stages to the ladder will not change the resistance of the network. We can apply the rules for resistance combination to the diagram shown to the right to obtain a quadratic equation in R_{eq} that we can solve for the equivalent resistance between points *a* and *b*.



(*a*) The equivalent resistance of the series combination of R and ($R \parallel R_{\text{eq}}$) is R_{eq}, so:

$$R_{\text{eq}} = R + R\|R_{\text{eq}} = R + \frac{RR_{\text{eq}}}{R + R_{\text{eq}}}$$

Simplify to obtain:

$$R_{\text{eq}}^2 - RR_{\text{eq}} - R^2 = 0$$

Solve for R_{eq} to obtain:

$$R_{\text{eq}} = \left(\frac{1+\sqrt{5}}{2}\right)R \approx \boxed{1.618R}$$

(*b*) The equivalent resistance of the series combination of R_1 and ($R_2 \parallel R_{eq}$) is R_{eq}, so:

$$R_{eq} = R_1 + R_2 \| R_{eq} = R_1 + \frac{R_2 R_{eq}}{R_2 + R_{eq}}$$

Simplify to obtain:

$$R_{eq}^2 - R_1 R_{eq} - R_1 R_2 = 0$$

Solve for the positive value of R_{eq} to obtain:

$$R_{eq} = \boxed{\frac{R_1 + \sqrt{R_1^2 + 4R_1 R_2}}{2}}$$

(*c*) If $R_1 = R_2 = R$, then:

$$R_{eq} = \frac{R + \sqrt{R^2 + 4RR}}{2} = \boxed{\left(\frac{1+\sqrt{5}}{2}\right)R}$$

in agreement with Part (*a*).

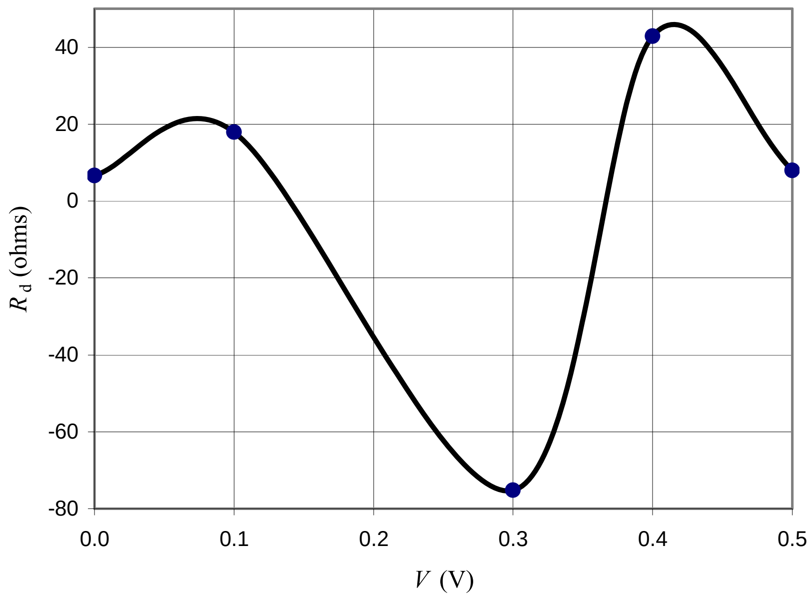
120 ••• A graph of current as a function of voltage for an Esaki diode is shown in Figure 25-81. (*a*) Make a graph of the differential resistance of the diode as a function of voltage. The differential resistance R_d of a circuit element is defined as $R_d = dV/dI$, where V is the voltage drop across the element and I is the current in the element. (*b*) At what value of the voltage drop does the differential resistance become negative? (*c*) What is the maximum differential resistance for this diode in the range shown and at what voltage does it occur? (*d*) Are there any places in the voltage range shown where the diode exhibits a differential resistance equal to zero? If so, under value(s) of the voltage does this (do these) occur?

Picture the Problem We can approximate the slope of the graph in Figure 25-81 and take its reciprocal to obtain values for R_d that we can plot as a function of V.

(*a*) Use the graph in Figure 25-81 to complete the table to the right.

V (V)	R_d (Ω)
0	6.67
0.1	17.9
0.3	−75.2
0.4	42.9
0.5	8

The following graph was plotted using a spreadsheet program.



(*b*) The differential resistance becomes negative at approximately 0.14 V.

(*c*) The maximum differential resistance for this diode is approximately 45 Ω and occurs at about 0.42 V.

(*d*) The diode exhibits no resistance where the curve crosses the V axis; that is at $V = 0.14$ V and 0.36 V.

Chapter 26
The Magnetic Field

Conceptual Problems

1 • [SSM] When the axis of a cathode-ray tube is horizontal in a region in which there is a magnetic field that is directed vertically upward, the electrons emitted from the cathode follow one of the dashed paths to the face of the tube in Figure 26-30. The correct path is (*a*) 1, (*b*) 2, (*c*) 3, (*d*) 4, (*e*) 5.

Determine the Concept Because the electrons are initially moving at 90° to the magnetic field, they will be deflected in the direction of the magnetic force acting on them. Use the right-hand rule based on the expression for the magnetic force acting on a moving charge $\vec{F} = q\vec{v} \times \vec{B}$, remembering that, for a negative charge, the force is in the direction opposite that indicated by the right-hand rule, to convince yourself that the particle will follow the path whose terminal point on the screen is 2. $\boxed{(b)}$ is correct.

2 •• We define the direction of the electric field to be the same as the direction of the force on a positive test charge. Why then do we *not* define the direction of the magnetic field to be the same as the direction of the magnetic force on a moving positive test charge?

Determine the Concept The direction of the force depends on the direction of the velocity. We do not define the direction of the magnetic field to be in the direction of the force because if we did, the magnetic field would be in a different direction each time the velocity was in a different direction. If this were the case, the magnetic field would not be a useful construct.

3 • [SSM] A *flicker bulb* is a light bulb that has a long, thin flexible filament. It is meant to be plugged into an ac outlet that delivers current at a frequency of 60 Hz. There is a small permanent magnet inside the bulb. When the bulb is plugged in the filament oscillates back and forth. At what frequency does it oscillate? Explain.

Determine the Concept Because the alternating current running through the filament is changing direction every 1/60 s, the filament experiences a force that changes direction at the frequency of the current.

4 • In a cyclotron, the potential difference between the dees oscillates with a period given by $T = 2\pi m/(qB)$. Show that the expression to the right of the equal sign has units of seconds if q, B and m have units of coulombs, teslas and kilograms, respectively.

Determine the Concept Substituting the SI units for q, B, and m yields:

$$\frac{\mathrm{C\cdot T}}{\mathrm{kg}}=\frac{\mathrm{C}\left(\frac{\mathrm{N}}{\mathrm{A\cdot m}}\right)}{\mathrm{kg}}=\frac{\mathrm{C}\left(\frac{\mathrm{N\cdot s}}{\mathrm{C\cdot m}}\right)}{\mathrm{kg}}=\frac{\frac{\frac{\mathrm{kg\cdot m}}{\mathrm{s^2}}\cdot\mathrm{s}}{\mathrm{m}}}{\mathrm{kg}}=\frac{\frac{\mathrm{kg\cdot m}}{\mathrm{s}}}{\mathrm{kg\cdot m}}=\boxed{\frac{1}{\mathrm{s}}}$$

5 • A ^{7}Li nucleus has a charge equal to $+3e$ and a mass that is equal to the mass of seven protons. A ^{7}Li nucleus and a proton are both moving perpendicular to a uniform magnetic field $\vec{B}$. The magnitude of the momentum of the proton is equal to the magnitude of the momentum of the nucleus. The path of the proton has a radius of curvature equal to R_p and the path of the ^{7}Li nucleus has a radius of curvature equal to R_Li. The ratio $R_\mathrm{p}/R_\mathrm{Li}$ is closest to (*a*) 3/1, (*b*) 1/3, (*c*) 1/7, (*d*) 7/1, (*e*) 3/7, (*f*) 7/3.

Determine the Concept We can use Newton's second law for circular motion to express the radius of curvature R of each particle in terms of its charge, momentum, and the magnetic field. We can then divide the proton's radius of curvature by that of the ^{7}Li nucleus to decide which of these alternatives is correct.

Apply Newton's second law to the lithium nucleus to obtain:

$$qvB=m\frac{v^2}{R}\Rightarrow R=\frac{mv}{qB}$$

For the ^{7}Li nucleus this becomes:

$$R_\mathrm{Li}=\frac{p_\mathrm{Li}}{3eB} \qquad (1)$$

For the proton we have:

$$R_\mathrm{p}=\frac{p_\mathrm{p}}{eB} \qquad (2)$$

Divide equation (2) by equation (1) and simplify to obtain:

$$\frac{R_\mathrm{p}}{R_\mathrm{Li}}=\frac{\frac{p_\mathrm{p}}{eB}}{\frac{p_\mathrm{Li}}{3eB}}=3\frac{p_\mathrm{p}}{p_\mathrm{Li}}$$

Because the momenta are equal:

$$\frac{R_\mathrm{p}}{R_\mathrm{Li}}=3\Rightarrow\boxed{(a)}\text{ is correct.}$$

6 • An electron moving in the $+x$ direction enters a region that has a uniform magnetic field in the $+y$ direction. When the electron enters this region, it will (*a*) be deflected toward the $+y$ direction, (*b*) be deflected toward the $-y$ direction, (*c*) be deflected toward the $+z$ direction, (*d*) be deflected toward the $-z$ direction, (*e*) continue undeflected in the $+x$ direction.

Determine the Concept Application of the right-hand rule indicates that a positively charged body would experience a downward force and, in the absence of other forces, be deflected downward. Because the direction of the magnetic force on an electron is opposite that of the force on a positively charged object, an electron will be deflected upward. $\boxed{(c)}$ is correct.

7 • **[SSM]** In a velocity selector, the speed of the undeflected charged particle is given by the ratio of the magnitude of the electric field to the magnitude of the magnetic field. Show that E/B in fact does have the units of m/s if E and B are in units of volts per meter and teslas, respectively.

Determine the Concept Substituting the SI units for E and B yields:

$$\frac{\dfrac{\text{N}}{\text{C}}}{\dfrac{\text{N}}{\text{A}\cdot\text{m}}}=\frac{\text{A}\cdot\text{m}}{\text{C}}==\frac{\dfrac{\text{C}}{\text{s}}\cdot\text{m}}{\text{C}}=\boxed{\frac{\text{m}}{\text{s}}}$$

8 • How are the properties of magnetic field lines similar to the properties of electric field lines? How are they different?

Similarities	Differences
1. Their density on a surface perpendicular to the lines is a measure of the strength of the field 2. The lines point in the direction of the field 3. The lines do not cross.	1. Magnetic field lines neither begin nor end. Electric field lines begin on positive charges and end on negative charges. 2. Electric forces are parallel or anti-parallel to the field lines. Magnetic forces are perpendicular to the field lines.

9 • True or false:

(*a*) The magnetic moment of a bar magnet points from its north pole to its south pole.
(*b*) Inside the material of a bar magnet, the magnetic field due to the bar magnet points from the magnet's south pole toward its north pole.
(*c*) If a current loop simultaneously has its current doubled and its area cut in half, then the magnitude of its magnetic moment remains the same.
(*d*) The maximum torque on a current loop placed in a magnetic field occurs when the plane of the loop is perpendicular to the direction of the magnetic field.

(*a*) False. By definition, the magnetic moment of a small bar magnet points from its south pole to its north pole.

(*b*) True. The external magnetic field of a bar magnet points from the north pole of the magnet to south pole. Because magnetic field lines are continuous, the magnet's internal field lines point from the south pole to the north pole.

(*c*) True. Because the magnetic dipole moment of a current loop is given by $\vec{\boldsymbol{\mu}} = NIA\vec{\boldsymbol{n}}$, simultaneously doubling the current and halving its area leaves the magnetic dipole moment unchanged.

(*d*) False. The magnitude of the torque acting on a magnetic dipole moment is given $\tau = \mu B\sin\theta$ where θ is the angle between the axis of the current loop and the direction of the magnetic field. When the plane of the loop is perpendicular to the field direction $\theta = 0$ and the torque is zero.

10 •• Show that the von Klitzing constant, h/e^2, gives the SI unit for resistance (the ohm) h and e are in units of joule seconds and coulombs, respectively.

Determine the Concept The von Klitzing resistance is related to the Hall resistance according to $R_K = nR_H$ where $R_K = h/e^2$.

Substituting the SI units of h and e yields: $\dfrac{\mathrm{J}\cdot\mathrm{s}}{\mathrm{C}^2} = \dfrac{\mathrm{J/C}}{\mathrm{C/s}} = \mathrm{V/A} = \boxed{\Omega}$

11 ••• The theory of relativity states that no law of physics can be described using the absolute velocity of an object, which is in fact impossible to define due to a lack of an absolute reference frame. Instead, the behavior of interacting objects can only be described by the relative velocities between the objects. New physical insights result from this idea. For example, in Figure 26-31 a magnet moving at high speed relative to some observer passes by an electron that is at rest relative to the same observer. Explain why you are sure that a force must be acting on the electron. In what direction will the force point at the instant the north pole of the magnet passes directly underneath the electron? Explain your answer.

Determine the Concept From relativity; this is equivalent to the electron moving from right to left at speed v with the magnet stationary. When the electron is directly over the magnet, the field points directly up, so there is a force directed out of the page on the electron.

Estimation and Approximation

12 • Estimate the maximum magnetic force per meter that Earth's magnetic field could exert on a current-carrying wire in a 20-A circuit in your house.

Picture the Problem Because the magnetic force on a current-carrying wire is given by $\vec{F} = I\vec{L} \times \vec{B}$, the maximum force occurs when θ = 90°. Under this condition, $F_{\text{max}} = ILB$.

The maximum force per unit length that Earth's magnetic field could exert on a current-carrying wire in your home is given by:

$$\left.\frac{F}{L}\right]_{\text{max}} = IB$$

For a 20-A circuit and $B = 0.5 \times 10^{-4}$ T:

$$\left.\frac{F}{L}\right]_{\text{max}} = (20\ \text{A})(0.5 \times 10^{-4}\ \text{T}) = \boxed{1\ \text{mN/m}}$$

13 •• Your friend wants to be magician and intends to use Earth's magnetic field to suspend a current-carrying wire above the stage. He asks you to estimate the minimum current needed to suspend the wire just above Earth's surface at the equator (where Earth's magnetic field is horizontal). Assume the wire has a linear mass density of 10 g/m. Would you advise him to proceed with his plans for this act?

Picture the Problem Because the magnetic force on a current-carrying wire is given by $\vec{F} = I\vec{L} \times \vec{B}$, the maximum force occurs when θ = 90°. Under this condition, $F_{\text{max}} = ILB$. In order to suspend the wire, this magnetic force would have to be equal in magnitude to the gravitational force exerted by Earth on the wire:

Letting the upward direction be the $+y$ direction, apply $\sum F_y = 0$ to the wire to obtain:

$$F_{\text{m}} - F_{\text{g}} = 0$$

or,

$$ILB - mg = 0$$

Solving for I yields:

$$I = \frac{mg}{LB} = \left(\frac{m}{L}\right)\frac{g}{B}$$

where m/L is the linear density of the wire.

Substitute numerical values and evaluate I:

$$I = (10\text{ g/m})\frac{9.81\text{ m/s}^2}{0.5\times10^{-4}\text{ T}} \approx \boxed{2\text{ kA}}$$

You should advise him to develop some other act. A current of 2000 A would overheat the wire (which is a gross understatement).

The Force Exerted by a Magnetic Field

14 • Find the magnetic force on a proton moving in the $+x$ direction at a speed of 0.446 Mm/s in a uniform magnetic field of 1.75 T in the $+z$ direction.

Picture the Problem The magnetic force acting on a charge is given by $\vec{F} = q\vec{v}\times\vec{B}$. We can express $\vec{v}$ and $\vec{B}$, form their vector ("cross") product, and multiply by the scalar q to find $\vec{F}$.

The magnetic force acting on the proton is given by:

$$\vec{F} = q\vec{v}\times\vec{B}$$

Express $\vec{v}$:

$$\vec{v} = (0.446\text{ Mm/s})\hat{i}$$

Express $\vec{B}$:

$$\vec{B} = (1.75\text{ T})\hat{k}$$

Substitute numerical values and evaluate $\vec{F}$:

$$\vec{F} = (1.602\times10^{-19}\text{ C})\left[(0.446\text{ Mm/s})\hat{i}\times(1.75\text{ T})\hat{k}\right] = \boxed{-(0.125\text{ pN})\hat{j}}$$

15 • A point particle has a charge equal to –3.64 nC and a velocity equal to 2.75×10^3 m/s $\hat{i}$. Find the force on the charge if the magnetic field is (*a*) $0.38\text{ T}\,\hat{j}$, (*b*) $0.75\text{ T}\,\hat{i} + 0.75\text{ T}\,\hat{j}$, (*c*) $0.65\text{ T}\,\hat{i}$, and (*d*) $0.75\text{ T}\,\hat{i} + 0.75\text{ T}\,\hat{k}$.

Picture the Problem The magnetic force acting on the charge is given by $\vec{F} = q\vec{v}\times\vec{B}$. We can express $\vec{v}$ and $\vec{B}$, form their vector (also known as the "cross") product, and multiply by the scalar q to find $\vec{F}$.

Express the force acting on the charge:

$$\vec{F} = q\vec{v}\times\vec{B}$$

Substitute numerical values to obtain:

$$\vec{F} = (-3.64\text{ nC})\left[(2.75\times10^3\text{ m/s})\hat{i}\times\vec{B}\right]$$

(a) Evaluate $\vec{F}$ for $\vec{B} = 0.38\ \text{T}\ \hat{j}$:

$$\vec{F} = (-3.64\,\text{nC})\left[(2.75\times10^3\ \text{m/s})\hat{i}\times(0.38\,\text{T})\hat{j}\right] = \boxed{-(3.8\,\mu\text{N})\hat{k}}$$

(b) Evaluate $\vec{F}$ for $\vec{B} = 0.75\ \text{T}\ \hat{i} + 0.75\ \text{T}\ \hat{j}$:

$$\vec{F} = (-3.64\,\text{nC})\left[(2.75\times10^3\ \text{m/s})\hat{i}\times\left\{(0.75\,\text{T})\hat{i}+(0.75\,\text{T})\hat{j}\right\}\right] = \boxed{-(7.5\,\mu\text{N})\hat{k}}$$

(c) Evaluate $\vec{F}$ for $\vec{B} = 0.65\ \text{T}\ \hat{i}$:

$$\vec{F} = (-3.64\,\text{nC})\left[(2.75\times10^3\ \text{m/s})\hat{i}\times(0.65\,\text{T})\hat{i}\right] = \boxed{0}$$

(d) Evaluate $\vec{F}$ for $\vec{B} = 0.75\ \text{T}\ \hat{i} + 0.75\ \text{T}\hat{k}$:

$$\vec{F} = (-3.64\,\text{nC})\left[(2.75\times10^3\ \text{m/s})\hat{i}\times(0.75\,\text{T})\hat{i}+(0.75\,\text{T})\hat{k}\right] = \boxed{(7.5\,\mu\text{N})\hat{j}}$$

16 • A uniform magnetic field equal to 1.48 T is in the +z direction. Find the force exerted by the field on a proton if the velocity of the proton is (a) $2.7\ \text{km/s}\ \hat{i}$, ($b$) $3.7\ \text{km/s}\ \hat{j}$, ($c$) $6.8\ \text{km/s}\ \hat{k}$, and ($d$) $4.0\ \text{km/s}\ \hat{i} + 3.0\ \text{km/s}\ \hat{j}$.

Picture the Problem The magnetic force acting on the proton is given by $\vec{F} = q\vec{v}\times\vec{B}$. We can express $\vec{v}$ and $\vec{B}$, form their vector product, and multiply by the scalar q to find $\vec{F}$.

The magnetic force acting on the proton is given by:

$$\vec{F} = q\vec{v}\times\vec{B}$$

(a) Evaluate $\vec{F}$ for $\vec{v} = 2.7\ \text{km/s}\ \hat{i}$:

$$\vec{F} = (1.602\times10^{-19}\ \text{C})\left[(2.7\,\text{km/s})\hat{i}\times(1.48\,\text{T})\hat{k}\right] = \boxed{-(6.4\times10^{-16}\ \text{N})\hat{j}}$$

(b) Evaluate $\vec{F}$ for $\vec{v} = 3.7\ \text{km/s}\ \hat{j}$:

$$\vec{F} = (1.602\times10^{-19}\ \text{C})\left[(3.7\,\text{km/s})\hat{j}\times(1.48\,\text{T})\hat{k}\right] = \boxed{(8.8\times10^{-16}\ \text{N})\hat{i}}$$

(c) Evaluate $\vec{F}$ for $\vec{v}$ = 6.8 km/s $\hat{k}$:

$$\vec{F} = \left(1.602\times10^{-19}\text{ C}\right)\left[\left(6.8\text{ km/s}\right)\hat{k}\times\left(1.48\text{ T}\right)\hat{k}\right] = \boxed{0}$$

(d) Evaluate $\vec{F}$ for $\vec{v} = 4.0\text{ km/s}\,\hat{i} + 3.0\text{ km/s}\,\hat{j}$:

$$\begin{aligned}\vec{F} &= \left(1.602\times10^{-19}\text{ C}\right)\left[\left\{\left(4.0\text{ km/s}\right)\hat{i} + \left(3.0\text{ km/s}\right)\hat{j}\right\}\times\left(1.48\text{ T}\right)\hat{k}\right]\\ &= \boxed{\left(7.1\times10^{-16}\text{ N}\right)\hat{i} - \left(9.5\times10^{-16}\text{ N}\right)\hat{j}}\end{aligned}$$

17 • A straight wire segment that is 2.0 m long makes an angle of 30º with a uniform 0.37-T magnetic field. Find the magnitude of the force on the wire if the wire carries a current of 2.6 A.

Picture the Problem The magnitude of the magnetic force acting on a segment of wire carrying a current I is given by $F = I\ell B\sin\theta$ where ℓ is the length of the segment of wire, B is the magnetic field, and θ is the angle between direction of the current in the segment of wire and the direction of the magnetic field.

Express the magnitude of the magnetic force acting on the segment of wire:

$$F = I\ell B\sin\theta$$

Substitute numerical values and evaluate F:

$$\begin{aligned}F &= \left(2.6\text{ A}\right)\left(2.0\text{ m}\right)\left(0.37\text{ T}\right)\sin30° \\ &= \boxed{0.96\text{ N}}\end{aligned}$$

18 • A straight segment of a current-carrying wire has a current element $I\vec{L}$, where I = 2.7 A and $\vec{L} = 3.0\text{ cm}\,\hat{i} + 4.0\text{ cm}\,\hat{j}$. The segment is in a region with a uniform magnetic field given by $1.3\text{ T}\hat{i}$. Find the force on the segment of wire.

Picture the Problem We can use $\vec{F} = I\vec{L}\times\vec{B}$ to find the force acting on the wire segment.

Express the force acting on the wire segment:

$$\vec{F} = I\vec{L}\times\vec{B}$$

Substitute numerical values and evaluate $\vec{F}$:

$$\begin{aligned}\vec{F} &= \left(2.7\text{ A}\right)\left[\left(3.0\text{ cm}\right)\hat{i} + \left(4.0\text{ cm}\right)\hat{j}\right]\times\left(1.3\text{ T}\right)\hat{i} \\ &= \boxed{-\left(0.14\text{ N}\right)\hat{k}}\end{aligned}$$

19 • What is the force on an electron that has a velocity equal to $2.0\times10^{6}\ \text{m/s}\,\hat{\boldsymbol{i}} - 3.0\times10^{6}\ \hat{\boldsymbol{j}}$ when it is in a region with a magnetic field given by $0.80\ \text{T}\,\hat{\boldsymbol{i}} + 0.60\ \text{T}\,\hat{\boldsymbol{k}}$?

Picture the Problem The magnetic force acting on the electron is given by $\vec{\boldsymbol{F}} = q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$.

The magnetic force acting on the proton is given by:

$$\vec{\boldsymbol{F}} = q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{F}}$:

$$\begin{aligned}\vec{\boldsymbol{F}} &= \left(-1.602\times10^{-19}\ \text{C}\right)\left[\left\{\left(2\ \text{Mm/s}\right)\hat{\boldsymbol{i}} - \left(3\ \text{Mm/s}\right)\hat{\boldsymbol{j}}\right\}\times\left(0.8\,\hat{\boldsymbol{i}} + 0.6\,\hat{\boldsymbol{j}} - 0.4\,\hat{\boldsymbol{k}}\right)\text{T}\right]\\ &= \left(-0.192\ \text{pN}\right)\hat{\boldsymbol{k}} + \left(-0.128\ \text{pN}\right)\hat{\boldsymbol{j}} + \left(-0.384\ \text{pN}\right)\hat{\boldsymbol{k}} + \left(-0.192\ \text{pN}\right)\hat{\boldsymbol{i}}\\ &= -\left(0.192\ \text{pN}\right)\hat{\boldsymbol{i}} - \left(0.128\ \text{pN}\right)\hat{\boldsymbol{j}} - \left(0.577\ \text{pN}\right)\hat{\boldsymbol{k}}\\ &= \boxed{-\left(0.19\ \text{pN}\right)\hat{\boldsymbol{i}} - \left(0.13\ \text{pN}\right)\hat{\boldsymbol{j}} - \left(0.58\ \text{pN}\right)\hat{\boldsymbol{k}}}\end{aligned}$$

20 •• The section of wire shown in Figure 26-32 carries a current equal to 1.8 A from *a* to *b*. The segment is in a region that has a magnetic field whose value is $1.2\ \text{T}\,\hat{\boldsymbol{k}}$. Find the total force on the wire and show that the total force is the same as if the wire were in the form of a straight wire directly from *a* to *b* and carrying the same current.

Picture the Problem We can use $\vec{\boldsymbol{F}} = I\vec{\ell}\times\vec{\boldsymbol{B}}$ to find the force acting on the segments of the wire as well as the magnetic force acting on the wire if it were a straight segment from *a* to *b*.

Express the magnetic force acting on the wire:

$$\vec{\boldsymbol{F}} = \vec{\boldsymbol{F}}_{3\,\text{cm}} + \vec{\boldsymbol{F}}_{4\,\text{cm}}$$

Evaluate $\vec{\boldsymbol{F}}_{3\,\text{cm}}$:

$$\begin{aligned}\vec{\boldsymbol{F}}_{3\,\text{cm}} &= \left(1.8\ \text{A}\right)\left[\left(3.0\ \text{cm}\right)\hat{\boldsymbol{i}}\times\left(1.2\ \text{T}\right)\hat{\boldsymbol{k}}\right]\\ &= \left(0.0648\ \text{N}\right)\left(-\hat{\boldsymbol{j}}\right)\\ &= -\left(0.0648\ \text{N}\right)\hat{\boldsymbol{j}}\end{aligned}$$

Evaluate $\vec{\boldsymbol{F}}_{4\,\text{cm}}$:

$$\begin{aligned}\vec{\boldsymbol{F}}_{4\,\text{cm}} &= \left(1.8\ \text{A}\right)\left[\left(4.0\ \text{cm}\right)\hat{\boldsymbol{j}}\times\left(1.2\ \text{T}\right)\hat{\boldsymbol{k}}\right]\\ &= \left(0.0864\ \text{N}\right)\hat{\boldsymbol{i}}\end{aligned}$$

Substitute to obtain:

$$\vec{F} = -(0.0648\,\text{N})\hat{j} + (0.0864\,\text{N})\hat{i} = \boxed{(86\,\text{mN})\hat{i} - (65\,\text{mN})\hat{j}}$$

If the wire were straight from *a* to *b*:

$$\vec{\ell} = (3.0\,\text{cm})\hat{i} + (4.0\,\text{cm})\hat{j}$$

The magnetic force acting on the wire is:

$$\vec{F} = (1.8\,\text{A})\left[(3.0\,\text{cm})\hat{i} + (4.0\,\text{cm})\hat{j}\right] \times (1.2\,\text{T})\hat{k} = -(0.0648\,\text{N})\hat{j} + (0.0864\,\text{N})\hat{i}$$
$$= \boxed{(86\,\text{mN})\hat{i} - (65\,\text{mN})\hat{j}}$$

in agreement with the result obtained above when we treated the two straight segments of the wire separately.

21 •• A straight, stiff, horizontal 25-cm-long wire that has a mass equal to 50 g is connected to a source of emf by light, flexible leads. A magnetic field of 1.33 T is horizontal and perpendicular to the wire. Find the current necessary to "float" the wire, that is, when it is released from rest it remains at rest.

Picture the Problem Because the magnetic field is horizontal and perpendicular to the wire, the force it exerts on the current-carrying wire will be vertical. Under equilibrium conditions, this upward magnetic force will be equal to the downward gravitational force acting on the wire.

Apply $\sum F_{\text{vertical}} = 0$ to the wire:

$$F_{\text{mag}} - w = 0$$

Express F_{mag}:

$$F_{\text{mag}} = I\ell B \text{ because } \theta = 90°.$$

Substitute for F_{mag} to obtain:

$$I\ell B - mg = 0 \Rightarrow I = \frac{mg}{\ell B}$$

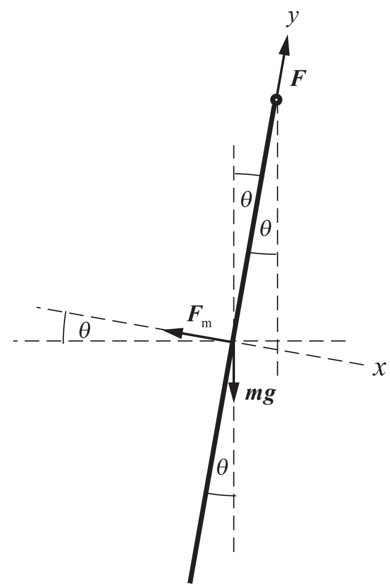
Substitute numerical values and evaluate I:

$$I = \frac{(50\,\text{g})(9.81\,\text{m/s}^2)}{(25\,\text{cm})(1.33\,\text{T})} = \boxed{1.5\,\text{A}}$$

22 •• In your physics laboratory class, you have constructed a simple *gaussmeter* for measuring the horizontal component of magnetic fields. The setup consists of a stiff 50-cm wire that hangs vertically from a conducting pivot so that its free end makes contact with a pool of mercury in a dish below (Figure 26-33). The mercury provides an electrical contact without constraining the movement of the wire. The wire has a mass of 5.0 g and conducts a current downward.
(*a*) What is the equilibrium angular displacement of the wire from vertical if the horizontal component of the magnetic field is 0.040 T and the current is 0.20 A?

(*b*) What is the sensitivity of this gaussmeter? That is, what is the ratio of the output to the input (in radians per tesla).

Picture the Problem The magnetic field is out of the page. The diagram shows the gaussmeter displaced from equilibrium under the influence of the gravitational force $m\vec{g}$, the magnetic force $\vec{F}_{\text{m}}$, and the force exerted by the conducting pivot $\vec{F}$. We can apply the condition for translational equilibrium in the *x* direction to find the equilibrium angular displacement of the wire from the vertical. In Part (*b*) we can solve the equation derived in Part (*a*) for *B* and evaluate this expression for the given data to find the horizontal magnetic field sensitivity of this gaussmeter.



(*a*) Apply $\sum F_x = 0$ to the wire to obtain:

$$\sum F_x = -F_{\text{m}} + mg\sin\theta = 0$$

The magnitude of the magnetic force acting on the wire is given by:

$F_{\text{m}} = I\ell B\sin\phi$

or, because $\phi = 90°$,

$F_{\text{m}} = I\ell B$

Substitute for F_{m} to obtain:

$$-I\ell B + mg\sin\theta = 0 \qquad (1)$$

Solving for θ yields:

$$\theta = \sin^{-1}\left[\frac{I\ell B}{mg}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{(0.20\,\text{A})(0.50\,\text{m})(0.040\,\text{T})}{(0.0050\,\text{kg})(9.81\,\text{m/s}^2)}\right] = 4.679° = \boxed{4.7°} = \boxed{82\,\text{mrad}}$$

(*b*) The sensitivity of this gaussmeter is the ratio of the output to the input:

$$\text{sensitivity} = \frac{\theta}{B}$$

Substitute numerical values and evaluate the sensitivity of the gaussmeter:

$$\text{sensitivity} = \frac{82\ \text{mrad}}{0.040\ \text{T}} = \boxed{2.0\ \text{rad/T}}$$

23 •• [SSM] A 10-cm long straight wire is parallel with the x axis and carries a current of 2.0 A in the $+x$ direction. The force on this wire due to the presence of a magnetic field $\vec{B}$ is $3.0\ \text{N}\hat{j} + 2.0\ \text{N}\hat{k}$. If this wire is rotated so that it is parallel with the y axis with the current in the $+y$ direction, the force on the wire becomes $-3.0\ \text{N}\hat{i} - 2.0\ \text{N}\hat{k}$. Determine the magnetic field $\vec{B}$.

Picture the Problem We can use the information given in the 1st and 2nd sentences to obtain an expression containing the components of the magnetic field $\vec{B}$. We can then use the information in the 1st and 3rd sentences to obtain a second equation in these components that we can solve simultaneously for the components of $\vec{B}$.

Express the magnetic field $\vec{B}$ in terms of its components:

$$\vec{B} = B_x\hat{i} + B_y\hat{j} + B_z\hat{k} \qquad (1)$$

Express $\vec{F}$ in terms of $\vec{B}$:

$$\begin{aligned}\vec{F} &= I\vec{\ell}\times\vec{B} = (2.0\,\text{A})\left[(0.10\,\text{m})\hat{i}\right]\times\left(B_x\hat{i} + B_y\hat{j} + B_z\hat{k}\right)\\ &= (0.20\,\text{A}\cdot\text{m})\hat{i}\times\left(B_x\hat{i} + B_y\hat{j} + B_z\hat{k}\right) = -(0.20\,\text{A}\cdot\text{m})B_z\hat{j} + (0.20\,\text{A}\cdot\text{m})B_y\hat{k}\end{aligned}$$

Equate the components of this expression for $\vec{F}$ with those given in the second sentence of the statement of the problem to obtain:

$$-(0.20\,\text{A}\cdot\text{m})B_z = 3.0\,\text{N}$$
and
$$(0.20\,\text{A}\cdot\text{m})B_y = 2.0\,\text{N}$$

Noting that B_x is undetermined, solve for B_z and B_y:

$$B_z = -15\,\text{T} \text{ and } B_y = 10\,\text{T}$$

When the wire is rotated so that the current flows in the positive y direction:

$$\begin{aligned}\vec{F} &= I\vec{\ell}\times\vec{B} = (2.0\,\text{A})\left[(0.10\,\text{m})\hat{j}\right]\times\left(B_x\hat{i} + B_y\hat{j} + B_z\hat{k}\right)\\ &= (0.20\,\text{A}\cdot\text{m})\hat{j}\times\left(B_x\hat{i} + B_y\hat{j} + B_z\hat{k}\right) = (0.20\,\text{A}\cdot\text{m})B_z\hat{i} - (0.20\,\text{A}\cdot\text{m})B_x\hat{k}\end{aligned}$$

Equate the components of this expression for $\vec{F}$ with those given in the third sentence of the problem statement to obtain:

$$(0.20\,\text{A}\cdot\text{m})B_x = -2.0\,\text{N}$$
and
$$-(0.20\,\text{A}\cdot\text{m})B_z = -3.0\,\text{N}$$

Solve for B_x and B_z to obtain:

$B_x = 10\,\text{T}$ and, in agreement with our results above, $B_z = -15\,\text{T}$

Substitute in equation (1) to obtain:

$$\vec{B} = \boxed{(10\,\text{T})\hat{\boldsymbol{i}} + (10\,\text{T})\hat{\boldsymbol{j}} - (15\,\text{T})\hat{\boldsymbol{k}}}$$

24 •• A 10-cm long straight wire is parallel with the z axis and carries a current of 4.0 A in the + z direction. The force on this wire due to a uniform magnetic field $\vec{B}$ is $-0.20\ \text{N}\,\hat{\boldsymbol{i}} + 0.20\ \text{N}\,\hat{\boldsymbol{j}}$. If this wire is rotated so that it is parallel with the x axis with the current is in the +x direction, the force on the wire becomes $0.20\,\hat{\boldsymbol{k}}\,\text{N}$. Find $\vec{B}$.

Picture the Problem We can use the information given in the 1st and 2nd sentences to obtain an expression containing the components of the magnetic field $\vec{B}$. We can then use the information in the 1st and 3rd sentences to obtain a second equation in these components that we can solve simultaneously for the components of $\vec{B}$.

Express the magnetic field $\vec{B}$ in terms of its components:

$$\vec{B} = B_x\hat{\boldsymbol{i}} + B_y\hat{\boldsymbol{j}} + B_z\hat{\boldsymbol{k}} \qquad (1)$$

Express $\vec{F}$ in terms of $\vec{B}$:

$$\begin{aligned}\vec{F} &= I\vec{\ell}\times\vec{B}\\ &= (4.0\,\text{A})\left[(0.1\,\text{m})\hat{\boldsymbol{k}}\right]\times\left(B_x\hat{\boldsymbol{i}} + B_y\hat{\boldsymbol{j}} + B_z\hat{\boldsymbol{k}}\right)\\ &= (0.40\,\text{A}\cdot\text{m})\hat{\boldsymbol{k}}\times\left(B_x\hat{\boldsymbol{i}} + B_y\hat{\boldsymbol{j}} + B_z\hat{\boldsymbol{k}}\right)\\ &= (0.40\,\text{A}\cdot\text{m})B_y\hat{\boldsymbol{j}} - (0.40\,\text{A}\cdot\text{m})B_y\hat{\boldsymbol{i}}\end{aligned}$$

Equate the components of this expression for $\vec{F}$ with those given in the second sentence of the statement of the problem to obtain:

$$(0.40\,\text{A}\cdot\text{m})B_y = 0.20\,\text{N}$$
and
$$(0.40\,\text{A}\cdot\text{m})B_x = 0.20\,\text{N}$$

Noting that B_z is undetermined, solve for B_x and B_y:

$B_x = 0.50\,\text{T}$ and $B_y = 0.50\,\text{T}$

When the wire is rotated so that the current flows in the positive x direction:

$$\vec{F} = I\vec{\ell} \times \vec{B} = (4.0\,\text{A})\left[(0.10\,\text{m})\hat{i}\right] \times \left(B_x\hat{i} + B_y\hat{j} + B_z\hat{k}\right)$$
$$= (0.40\,\text{A}\cdot\text{m})\hat{i} \times \left(B_x\hat{i} + B_y\hat{j} + B_z\hat{k}\right) = -(0.40\,\text{A}\cdot\text{m})B_z\hat{j} + (0.40\,\text{A}\cdot\text{m})B_y\hat{k}$$

Equate the components of this expression for $\vec{F}$ with those given in the third sentence of the problem statement to obtain:

$$-(0.40\,\text{A}\cdot\text{m})B_z = 0$$
and
$$(0.40\,\text{A}\cdot\text{m})B_y = 0.2\,\text{N}$$

Solve for B_z and B_y to obtain:

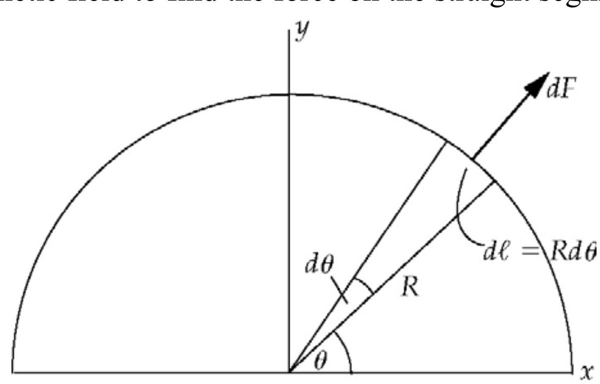
$$B_z = 0$$
and, in agreement with our results above,
$$B_y = 0.50\,\text{T}$$

Substitute in equation (1) to obtain:

$$\vec{B} = \boxed{(0.50\,\text{T})\hat{i} + (0.50\,\text{T})\hat{j}}$$

25 •• [SSM] A current-carrying wire is bent into a closed semicircular loop of radius R that lies in the xy plane (Figure 26-34). The wire is in a uniform magnetic field that is in the $+z$ direction, as shown. Verify that the force acting on the loop is zero.

Picture the Problem With the current in the direction indicated and the magnetic field in the z direction, pointing out of the plane of the page, the force is in the radial direction and we can integrate the element of force dF acting on an element of length $d\ell$ between $\theta = 0$ and π to find the force acting on the semicircular portion of the loop and use the expression for the force on a current-carrying wire in a uniform magnetic field to find the force on the straight segment of the loop.



Express the net force acting on the semicircular loop of wire:

$$\vec{F} = \vec{F}_{\substack{\text{semicircular}\\\text{loop}}} + \vec{F}_{\substack{\text{straight}\\\text{segment}}} \qquad (1)$$

Express the force acting on the straight segment of the loop:

$$\vec{F}_{\substack{\text{straight}\\ \text{segment}}} = I\vec{\ell} \times \vec{B} = 2RI\hat{i} \times B\hat{k} = -2RIB\hat{j}$$

Express the force dF acting on the element of the wire of length $d\ell$:

$$dF = Id\ell B = IRBd\theta$$

Express the x and y components of dF:

$$dF_x = dF\cos\theta \text{ and } dF_y = dF\sin\theta$$

Because, by symmetry, the x component of the force is zero, we can integrate the y component to find the force on the wire:

$$dF_y = IRB\sin\theta\, d\theta$$

and

$$\vec{F}_{\substack{\text{semicircular}\\ \text{loop}}} = F_y\hat{j} = \left(RIB\int_0^{\pi}\sin\theta\, d\theta\right)\hat{j}$$
$$= 2RIB\hat{j}$$

Substitute in equation (1) to obtain:

$$\vec{F} = 2RIB\hat{j} - 2RIB\hat{j} = \boxed{0}$$

26 ••• A wire bent in some arbitrary shape carries a current I. The wire is in a region with a uniform magnetic field $\vec{B}$. Show that the total force on the part of the wire from some arbitrary point on the wire (designated as a) to some other arbitrary point on the wire (designated as b) is $\vec{F} = I\vec{L} \times \vec{B}$, where $\vec{L}$ is the vector from point a to point b. In other words, show that the force on an arbitrary section of the bent wire is the same as the force would be on a straight section wire carrying the same current and connecting the two endpoints of the arbitrary section.

Picture the Problem We can integrate the expression for the force $d\vec{F}$ acting on an element of the wire of length $d\vec{L}$ from a to b to show that $\vec{F} = I\vec{L} \times \vec{B}$.

Express the force $d\vec{F}$ acting on the element of the wire of length $d\vec{L}$:

$$d\vec{F} = Id\vec{L} \times \vec{B}$$

Integrate this expression to obtain:

$$\vec{F} = \int_a^b Id\vec{L} \times \vec{B}$$

Because $\vec{B}$ and I are constant:

$$\vec{F} = I\left(\int_a^b d\vec{L}\right) \times \vec{B} = \boxed{I\vec{L} \times \vec{B}}$$

where $\vec{L}$ is the vector from a to b.

Motion of a Point Charge in a Magnetic Field

27 • [SSM] A proton moves in a 65-cm-radius circular orbit that is perpendicular to a uniform magnetic field of magnitude 0.75 T. (*a*) What is the orbital period for the motion? (*b*) What is the speed of the proton? (*c*) What is the kinetic energy of the proton?

Picture the Problem We can apply Newton's second law to the orbiting proton to relate its speed to its radius. We can then use $T = 2\pi r/v$ to find its period. In Part (*b*) we can use the relationship between T and v to determine v. In Part (*c*) we can use its definition to find the kinetic energy of the proton.

(*a*) Relate the period T of the motion of the proton to its orbital speed v:

$$T = \frac{2\pi r}{v} \quad (1)$$

Apply Newton's second law to the proton to obtain:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Substitute for r in equation (1) and simplify to obtain:

$$T = \frac{2\pi m}{qB}$$

Substitute numerical values and evaluate T:

$$T = \frac{2\pi\left(1.673\times10^{-27}\ \text{kg}\right)}{\left(1.602\times10^{-19}\ \text{C}\right)\left(0.75\,\text{T}\right)} = 87.4\,\text{ns}$$
$$= \boxed{87\,\text{ns}}$$

(*b*) From equation (1) we have:

$$v = \frac{2\pi r}{T}$$

Substitute numerical values and evaluate v:

$$v = \frac{2\pi\left(0.65\,\text{m}\right)}{87.4\,\text{ns}} = 4.67\times10^{7}\ \text{m/s}$$
$$= \boxed{4.7\times10^{7}\ \text{m/s}}$$

(*c*) Using its definition, express and evaluate the kinetic energy of the proton:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}\left(1.673\times10^{-27}\ \text{kg}\right)\left(4.67\times10^{7}\ \text{m/s}\right)^2 = 1.82\times10^{-12}\ \text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}}$$
$$= \boxed{11\,\text{MeV}}$$

28 • A 4.5-keV electron (an electron that has a kinetic energy equal to 4.5 keV) moves in a circular orbit that is perpendicular to a magnetic field of 0.325 T. (*a*) Find the radius of the orbit. (*b*) Find the frequency and period of the orbital motion.

Picture the Problem (*a*) We can apply Newton's second law to the orbiting electron to obtain an expression for the radius of its orbit as a function of its mass *m*, charge *q*, speed *v*, and the magnitude of the magnetic field *B*. Using the definition of kinetic energy will allow us to express *r* in terms of *m*, *q*, *B*, and the electron's kinetic energy *K*. (*b*) The period of the orbital motion is given by $T = 2\pi r/v$. Substituting for *r* (or r/v) from Part (*a*) will eliminate the orbital speed of the electron and leave us with an expression for *T* that depends only on *m*, *q*, and *B*. The frequency of the orbital motion is the reciprocal of the period of the orbital motion.

(*a*) Apply Newton's second law to the orbiting electron to obtain:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Express the kinetic energy of the electron:

$$K = \tfrac{1}{2}mv^2 \Rightarrow v = \sqrt{\frac{2K}{m}}$$

Substituting for *v* in the expression for *r* and simplifying yields:

$$r = \frac{m}{qB}\sqrt{\frac{2K}{m}} = \frac{\sqrt{2Km}}{qB}$$

Substitute numerical values and evaluate *r*:

$$r = \frac{\sqrt{2(4.5\,\text{keV})\left(9.109\times10^{-31}\,\text{kg}\right)\left(\dfrac{1.602\times10^{-19}\,\text{J}}{\text{eV}}\right)}}{\left(1.602\times10^{-19}\,\text{C}\right)(0.325\,\text{T})} = 0.696\,\text{mm} = \boxed{0.70\,\text{mm}}$$

(*b*) Relate the period of the electron's motion to the radius of its orbit and its orbital speed:

$$T = \frac{2\pi r}{v}$$

Because $r = \dfrac{mv}{qB}$:

$$T = \frac{2\pi\dfrac{mv}{qB}}{v} = \frac{2\pi\, m}{qB}$$

Substitute numerical values and evaluate T:

$$T = \frac{2\pi\left(9.109\times10^{-31}\ \text{kg}\right)}{\left(1.602\times10^{-19}\ \text{C}\right)\left(0.325\ \text{T}\right)} = 1.099\times10^{-10}\ \text{s} = \boxed{0.11\ \text{ns}}$$

The frequency of the motion is known as the cyclotron frequency and is the reciprocal of the period of the electron's motion:

$$f = \frac{1}{T} = \frac{1}{0.110\ \text{ns}} = \boxed{9.1\ \text{GHz}}$$

29 •• A proton, a deuteron and an alpha particle in a region with a uniform magnetic field each follow circular paths that have the same radius. The deuteron has a charge that is equal to the charge a proton has, and an alpha particle has a charge that is equal to twice the charge a proton has. Assume that $m_\alpha = 2m_\text{d} = 4m_\text{p}$. Compare (*a*) their speeds, (*b*) their kinetic energies, and (*c*) the magnitudes of their angular momenta about the centers of the orbits.

Picture the Problem We can apply Newton's second law to the orbiting particles to derive an expression for their orbital speeds as a function of their charge, their mass, the magnetic field in which they are moving, and the radii of their orbits. We can then compare their speeds by expressing their ratios. In Parts (*b*) and (*c*) we can proceed similarly starting with the definitions of kinetic energy and angular momentum.

(*a*) Apply Newton's second law to an orbiting particle to obtain:

$$qvB = m\frac{v^2}{r} \Rightarrow v = \frac{qBr}{m}$$

The speeds of the orbiting particles are given by:

$$v_\text{p} = \frac{q_\text{p}Br}{m_\text{p}}, \qquad (1)$$

$$v_\alpha = \frac{q_\alpha Br}{m_\alpha}, \text{ and} \qquad (2)$$

$$v_\text{d} = \frac{q_\text{d}Br}{m_\text{d}} \qquad (3)$$

Divide equation (2) by equation (1) and simplify to obtain:

$$\frac{v_\alpha}{v_\text{p}} = \frac{\dfrac{q_\alpha Br}{m_\alpha}}{\dfrac{q_\text{p}Br}{m_\text{p}}} = \frac{q_\alpha m_\text{p}}{q_\text{p}m_\alpha} = \frac{2em_\text{p}}{e\left(4m_\text{p}\right)} = \tfrac{1}{2}$$

or

$$2v_\alpha = v_\text{p}$$

Divide equation (3) by equation (1) and simplify to obtain:

$$\frac{v_\mathrm{d}}{v_\mathrm{p}}=\frac{\dfrac{q_\mathrm{d}Br}{m_\mathrm{d}}}{\dfrac{q_\mathrm{p}Br}{m_\mathrm{p}}}=\frac{q_\mathrm{d}m_\mathrm{p}}{q_\mathrm{p}m_\mathrm{d}}=\frac{em_\mathrm{p}}{e(2m_\mathrm{p})}=\tfrac{1}{2}$$

or

$$2v_\mathrm{d}=v_\mathrm{p}$$

Combining these results yields:

$$\boxed{2v_\alpha=2v_\mathrm{d}=v_\mathrm{p}}$$

(*b*) Using the expression for its orbital speed derived in (*a*), express the kinetic energy of an orbiting particle:

$$K=\tfrac{1}{2}mv^2=\tfrac{1}{2}m\left(\frac{qBr}{m}\right)^2=\frac{q^2B^2r^2}{2m}$$

The kinetic energies of the three particles are given by:

$$K_\mathrm{p}=\frac{q_\mathrm{p}^2B^2r^2}{2m_\mathrm{p}},\qquad(4)$$

$$K_\alpha=\frac{q_\alpha^2B^2r^2}{2m_\alpha},\ \text{and}\qquad(5)$$

$$K_\mathrm{d}=\frac{q_\mathrm{d}^2B^2r^2}{2m_\mathrm{d}}\qquad(6)$$

Dividing equation (7) by equation (6) and simplifying yields:

$$\frac{K_\alpha}{K_\mathrm{p}}=\frac{\tfrac{1}{2}\dfrac{q_\alpha^2B^2r^2}{m_\alpha}}{\tfrac{1}{2}\dfrac{q_\mathrm{p}^2B^2r^2}{m_\mathrm{p}}}=\frac{q_\alpha^2m_\mathrm{p}}{q_\mathrm{p}^2m_\alpha}=\frac{(2e)^2m_\mathrm{p}}{e^2(4m_\mathrm{p})}$$

$$=1\Rightarrow K_\alpha=K_\mathrm{p}$$

Divide equation (8) by equation (6) and simplify to obtain:

$$\frac{K_\mathrm{d}}{K_\mathrm{p}}=\frac{\dfrac{q_\mathrm{d}^2B^2r^2}{2m_\mathrm{d}}}{\dfrac{q_\mathrm{p}^2B^2r^2}{2m_\mathrm{p}}}=\frac{q_\mathrm{d}^2m_\mathrm{p}}{q_\mathrm{p}^2m_\mathrm{d}}=\frac{e^2m_\mathrm{p}}{e^2(2m_\mathrm{p})}$$

$$=\tfrac{1}{2}\Rightarrow K_\mathrm{p}=2K_\mathrm{d}$$

Combining these results yields:

$$\boxed{K_\alpha=2K_\mathrm{d}=K_\mathrm{p}}$$

(*c*) The angular momenta of the orbiting particles are given by:

$$L_p = m_p v_p r\,,$$
$$L_\alpha = m_\alpha v_\alpha r\,, \text{ and}$$
$$L_d = m_d v_d r$$

Express the ratio of L_α to L_p:

$$\frac{L_\alpha}{L_p} = \frac{m_\alpha v_\alpha r}{m_p v_p r} = \frac{(4m_p)\left(\frac{1}{2}v_p\right)}{m_p v_p} = 2$$
or
$$L_\alpha = 2L_p$$

Express the ratio of L_d to L_p:

$$\frac{L_d}{L_p} = \frac{m_d v_d r}{m_p v_p r} = \frac{(2m_p)\left(\frac{1}{2}v_p\right)}{m_p v_p} = 1$$
or
$$L_d = L_p$$

Combining these results yields:

$$\boxed{L_\alpha = 2L_d = 2L_p}$$

30 •• A particle has a charge q, a mass m, a linear momentum of magnitude p and a kinetic energy K. The particle moves in a circular orbit of radius R perpendicular to a uniform magnetic field $\vec{B}$. Show that (*a*) $p = BqR$ and (*b*) $K = \frac{1}{2}B^2q^2R^2/m$.

Picture the Problem We can use the definition of momentum to express p in terms of v and apply Newton's second law to the orbiting particle to express v in terms of q, B, R, and m. In Part (*b*) we can express the particle's kinetic energy in terms of its momentum and use our result from Part (*a*) to show that $K = \frac{1}{2}B^2q^2R^2/m.$

(*a*) Express the momentum of the particle:

$$p = mv \qquad (1)$$

Apply $\sum F_{\text{radial}} = ma_c$ to the orbiting particle to obtain:

$$qvB = m\frac{v^2}{R} \Rightarrow v = \frac{qBR}{m}$$

Substitute for v in equation (1) to obtain:

$$p = m\left(\frac{qBR}{m}\right) = \boxed{qBR}$$

(*b*) Express the kinetic energy of the orbiting particle as a function of its momentum:

$$K = \frac{p^2}{2m}$$

Substitute our result for *p* from Part (*a*) to obtain:

$$K = \frac{(qBR)^2}{2m} = \boxed{\frac{q^2B^2R^2}{2m}}$$

31 •• **[SSM]** A beam of particles with velocity $\vec{v}$ enters a region that has a uniform magnetic field $\vec{B}$ in the $+x$ direction. Show that when the x component of the displacement of one of the particles is $2\pi(m/qB)v\cos\theta$, where θ is the angle between $\vec{v}$ and $\vec{B}$, the velocity of the particle is in the same direction as it was when the particle entered the field.

Picture the Problem The particle's velocity has a component v_1 parallel to $\vec{B}$ and a component v_2 normal to $\vec{B}$. $v_1 = v\cos\theta$ and is constant, whereas $v_2 = v\sin\theta$, being normal to $\vec{B}$, will result in a magnetic force acting on the beam of particles and circular motion perpendicular to $\vec{B}$. We can use the relationship between distance, rate, and time and Newton's second law to express the distance the particle moves in the direction of the field during one period of the motion.

Express the distance moved in the direction of $\vec{B}$ by the particle during one period:

$$x = v_1T \qquad (1)$$

Express the period of the circular motion of the particles in the beam:

$$T = \frac{2\pi r}{v_2} \qquad (2)$$

Apply Newton's second law to a particle in the beam to obtain:

$$qv_2B = m\frac{v_2^2}{r} \Rightarrow v_2 = \frac{qBr}{m}$$

Substituting for v_2 in equation (2) and simplifying yields:

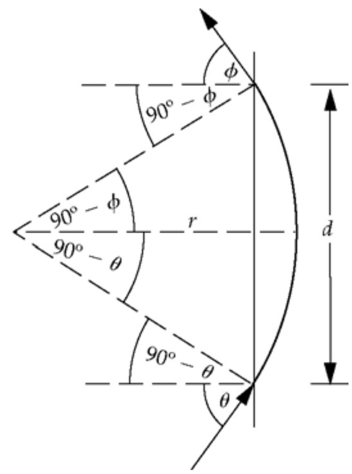
$$T = \frac{2\pi r}{\frac{qBr}{m}} = \frac{2\pi m}{qB}$$

Because $v_1 = v\cos\theta$, equation (1) becomes:

$$x = (v\cos\theta)\left(\frac{2\pi m}{qB}\right) = \boxed{2\pi\left(\frac{m}{qB}\right)v\cos\theta}$$

32 •• A proton that has a speed equal to 1.00×10^6 m/s enters a region that has a uniform magnetic field that has a magnitude of 0.800 T and points into the page, as shown in Figure 26-35. The proton enters the region at an angle θ = 60º. Find the exit angle ϕ and the distance d.

Picture the Problem The trajectory of the proton is shown to the right. We know that, because the proton enters the uniform field perpendicularly to the field, its trajectory while in the field will be circular. We can use symmetry considerations to determine ϕ. The application of Newton's second law to the proton while it is in the magnetic field and of trigonometry will allow us to conclude that $r = d$ and to determine the value of d.



From symmetry, it is evident that the angle θ in Figure 26-35 equals the angle ϕ:

$$\phi = \boxed{60°}$$

Apply $\sum F_{\text{radial}} = ma_c$ to the proton while it is in the magnetic field to obtain:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Use trigonometry to obtain:

$$\sin(90° - \theta) = \sin 30° = \frac{1}{2} = \frac{d/2}{r}$$

Solving for d yields:

$$r = d$$

Substitute for r to obtain:

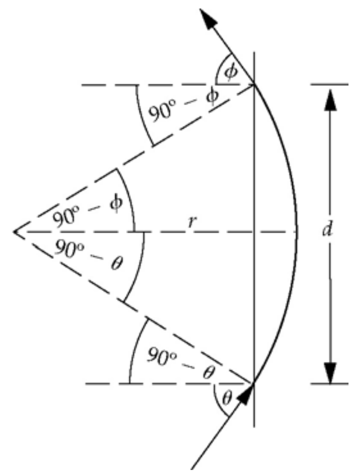
$$d = \frac{mv}{qB}$$

Substitute numerical values and evaluate d:

$$d = r = \frac{(1.673\times10^{-27}\text{ kg})(1.00\times10^{6}\text{ m/s})}{(1.602\times10^{-19}\text{ C})(0.800\text{ T})} = \boxed{13.1\text{ mm}}$$

33 •• [SSM] Suppose that in Figure 26-35, the magnetic field has a magnitude of 60 mT, the distance d is 40 cm, and θ is 24º. Find the speed v at which a particle enters the region and the exit angle ϕ if the particle is a (*a*) proton and (*b*) deuteron. Assume that $m_d = 2m_p$.

Picture the Problem The trajectory of the proton is shown to the right. We know that, because the proton enters the uniform field perpendicularly to the field, its trajectory while in the field will be circular. We can use symmetry considerations to determine ϕ. The application of Newton's second law to the proton and deuteron while they are in the uniform magnetic field will allow us to determine the values of v_p and v_d.



(*a*) From symmetry, it is evident that the angle θ in Figure 26-35 equals the angle ϕ:

$$\phi = \boxed{24°}$$

Apply $\sum F_{\text{radial}} = ma_c$ to the proton while it is in the magnetic field to obtain:

$$q_p v_p B = m_p \frac{v_p^2}{r_p} \Rightarrow v_p = \frac{q_p r_p B}{m_p} \quad (1)$$

Use trigonometry to obtain:

$$\sin(90° - \theta) = \sin 66° = \frac{d/2}{r}$$

Solving for r yields:

$$r = \frac{d}{2\sin 66°}$$

Substituting for r in equation (1) and simplifying yields:

$$v_p = \frac{q_p B d}{2m_p \sin 66°} \quad (2)$$

Substitute numerical values and evaluate v_p:

$$v_p = \frac{(1.602\times10^{-19}\ \text{C})(60\ \text{mT})(0.40\ \text{m})}{2(1.673\times10^{-27}\ \text{kg})\sin 66°} = \boxed{1.3\times10^{6}\ \text{m/s}}$$

(*b*) From symmetry, it is evident that the angle θ in Figure 26-35 equals the angle ϕ:

$\phi = \boxed{24°}$ independently of whether the particles are protons or deuterons.

For deuterons equation (2) becomes:

$$v_d = \frac{q_d Bd}{2m_d \sin 66°}$$

Because $m_d = 2m_p$ and $q_d = q_p$:

$$v_d \approx \frac{q_p Bd}{2(2m_p)\sin 66°} = \frac{q_p Bd}{4m_p \sin 66°}$$

Substitute numerical values and evaluate v_d:

$$v_d = \frac{(1.602\times10^{-19}\text{ C})(60\text{ mT})(0.40\text{ m})}{4(1.673\times10^{-27}\text{ kg})\sin 66°} = \boxed{6.3\times10^5\text{ m/s}}$$

34 •• The galactic magnetic field in some region of interstellar space has a magnitude of 1.00×10^{-9} T. A particle of interstellar dust has a mass of 10.0 μg and a total charge of 0.300 nC. How many years does it take for the particle to complete revolution of the circular orbit caused by its interaction with the magnetic field?

Picture the Problem We can apply Newton's second law of motion to express the orbital speed of the particle and then find the period of the dust particle from this orbital speed. Assume that the particle moves in a direction perpendicular to $\vec{B}$.

The period of the dust particle's motion is given by:

$$T = \frac{2\pi r}{v}$$

Apply $\sum F = ma_c$ to the particle:

$$qvB = m\frac{v^2}{r} \Rightarrow v = \frac{qBr}{m}$$

Substitute for v in the expression for T and simplify:

$$T = \frac{2\pi rm}{qBr} = \frac{2\pi m}{qB}$$

Substitute numerical values and evaluate T:

$$T = \frac{2\pi(10.0\times10^{-6}\text{ g}\times10^{-3}\text{ kg/g})}{(0.300\text{ nC})(1.00\times10^{-9}\text{ T})}$$

$$= 2.094\times10^{11}\text{ s}\times\frac{1\text{ y}}{31.56\text{ Ms}}$$

$$= \boxed{6.64\times10^3\text{ y}}$$

Applications of the Magnetic Force Acting on Charged Particles

35 • **[SSM]** A velocity selector has a magnetic field that has a magnitude equal to 0.28 T and is perpendicular to an electric field that has a magnitude equal

to 0.46 MV/m. (*a*) What must the speed of a particle be for that particle to pass through the velocity selector undeflected? What kinetic energy must (*b*) protons and (*c*) electrons have in order to pass through the velocity selector undeflected?

Picture the Problem Suppose that, for positively charged particles, their motion is from left to right through the velocity selector and the electric field is upward. Then the magnetic force must be downward and the magnetic field out of the page. We can apply the condition for translational equilibrium to relate v to E and B. In (*b*) and (*c*) we can use the definition of kinetic energy to find the energies of protons and electrons that pass through the velocity selector undeflected.

(*a*) Apply $\sum F_y = 0$ to the particle to obtain:

$$F_{\text{elec}} - F_{\text{mag}} = 0$$

or

$$qE - qvB = 0 \Rightarrow v = \frac{E}{B}$$

Substitute numerical values and evaluate v:

$$v = \frac{0.46\,\text{MV/m}}{0.28\,\text{T}} = 1.64\times10^{6}\ \text{m/s} = \boxed{1.6\times10^{6}\ \text{m/s}}$$

(*b*) The kinetic energy of protons passing through the velocity selector undeflected is:

$$K_{\text{p}} = \tfrac{1}{2}m_{\text{p}}v^2 = \tfrac{1}{2}\left(1.673\times10^{-27}\,\text{kg}\right)\left(1.64\times10^{6}\ \text{m/s}\right)^2 = 2.26\times10^{-15}\ \text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}} = \boxed{14\,\text{keV}}$$

(*c*) The kinetic energy of electrons passing through the velocity selector undeflected is:

$$K_{\text{e}} = \tfrac{1}{2}m_{\text{e}}v^2 = \tfrac{1}{2}\left(9.109\times10^{-31}\,\text{kg}\right)\left(1.64\times10^{6}\ \text{m/s}\right)^2 = 1.23\times10^{-18}\ \text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}} = \boxed{7.7\,\text{eV}}$$

36 •• A beam of protons is moving in the +*x* direction with a speed of 12.4 km/s through a region in which the electric field is perpendicular to the magnetic field. The beam is not deflected in this region. (*a*) If the magnetic field has a magnitude of 0.85 T and points in the + *y* direction, find the magnitude and direction of the electric field. (*b*) Would electrons that have the same velocity as the protons be deflected by these fields? If so, in what direction would they be deflected? If not, why not?

Picture the Problem Because the beam of protons is not deflected; we can conclude that the electric force acting on them is balanced by the magnetic force. Hence, we can find the magnetic force from the given data and use its definition to express the electric field.

(*a*) Because the beam of protons is not deflected:

$$\vec{F}_{\text{elec}} + \vec{F}_{\text{mag}} = 0$$

or

$$q\vec{E} + q\left(v\hat{\boldsymbol{i}} \times B\hat{\boldsymbol{j}}\right) = 0$$

Solving for $\vec{E}$ gives:

$$\vec{E} = -\left(v\hat{\boldsymbol{i}} \times B\hat{\boldsymbol{j}}\right) = -vB\hat{\boldsymbol{k}}$$

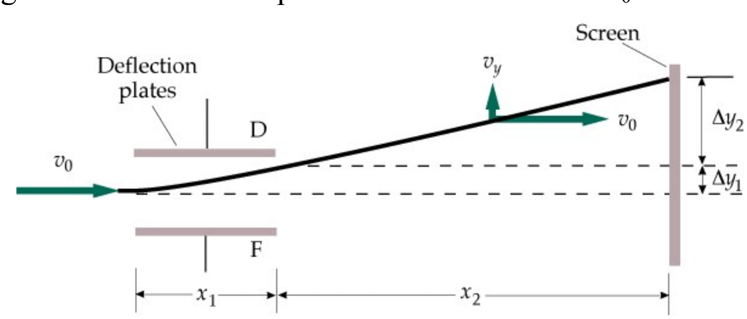
Substitute numerical values and evaluate $\vec{E}$:

$$\vec{E} = -(12.4\text{ km/s})(0.85\text{ T})\hat{\boldsymbol{k}}$$
$$= \boxed{-(11\text{kV/m})\hat{\boldsymbol{k}}}$$

(*b*) Because both $\vec{F}_{\text{mag}}$ and $\vec{F}_{\text{elec}}$ would be reversed, electrons are not deflected either.

37 •• The plates of a Thomson q/m apparatus are 6.00 cm long and are separated by 1.20 cm. The end of the plates is 30.0 cm from the tube screen. The kinetic energy of the electrons is 2.80 keV. If a potential difference of 25.0 V is applied across the deflection plates, by how much will the point where the beam strikes the screen displaced?

Picture the Problem Figure 26-18 is reproduced below. We can express the total deflection of the electron beam as the sum of the deflections while the beam is in the field between the plates and its deflection while it is in the field-free space. We can, in turn, use constant-acceleration equations to express each of these deflections. The resulting equation is in terms of v_0 and E. We can find v_0 from the kinetic energy of the beam and E from the potential difference across the plates and their separation. In Part (*b*) we can equate the electric and magnetic forces acting on an electron to express B in terms of E and v_0.



Express the total deflection Δy of the electrons:

$$\Delta y = \Delta y_1 + \Delta y_2 \qquad (1)$$

where Δy_1 is the deflection of the beam while it is in the electric field and Δy_2 is the deflection of the beam while it travels along a straight-line path outside the electric field.

Use a constant-acceleration equation to express Δy_1:

$$\Delta y_1 = \tfrac{1}{2} a_y (\Delta t)^2 \qquad (2)$$

where $\Delta t = x_1/v_0$ is the time an electron is in the electric field between the plates.

Apply Newton's second law to an electron between the plates to obtain:

$$qE = ma_y \Rightarrow a_y = \frac{qE}{m}$$

Substitute for a_y in equation (2) to obtain:

$$\Delta y_1 = \tfrac{1}{2}\left(\frac{qE}{m}\right)\left(\frac{x_1}{v_0}\right)^2 \qquad (3)$$

Express the vertical deflection Δy_2 of the electrons once they are out of the electric field:

$$\Delta y_2 = v_y \Delta t_2 \qquad (4)$$

Use a constant-acceleration equation to find the vertical speed of an electron as it leaves the electric field:

$$\begin{aligned} v_y &= v_{0y} + a_y \Delta t_1 \\ &= 0 + \frac{qE}{m}\left(\frac{x_1}{v_0}\right) \end{aligned}$$

Substitute in equation (4) to obtain:

$$\Delta y_2 = \frac{qE}{m}\left(\frac{x_1}{v_0}\right)\left(\frac{x_2}{v_0}\right) = \frac{qEx_1x_2}{mv_0^2} \qquad (5)$$

Substitute equations (3) and (5) in equation (1) to obtain:

$$\Delta y = \tfrac{1}{2}\left(\frac{qE}{m}\right)\left(\frac{x_1}{v_0}\right)^2 + \frac{qEx_1x_2}{mv_0^2}$$

or

$$\Delta y = \frac{qEx_1}{mv_0^2}\left(\frac{x_1}{2} + x_2\right) \qquad (6)$$

Use the definition of kinetic energy to express the square of the speed of the electrons:

$$K = \tfrac{1}{2}mv_0^2 \Rightarrow v_0^2 = \frac{2K}{m}$$

Express the electric field between the plates in terms of their potential difference:

$$E = \frac{V}{d}$$

Substituting for E and v_0^2 in equation (6) and simplifying yields:

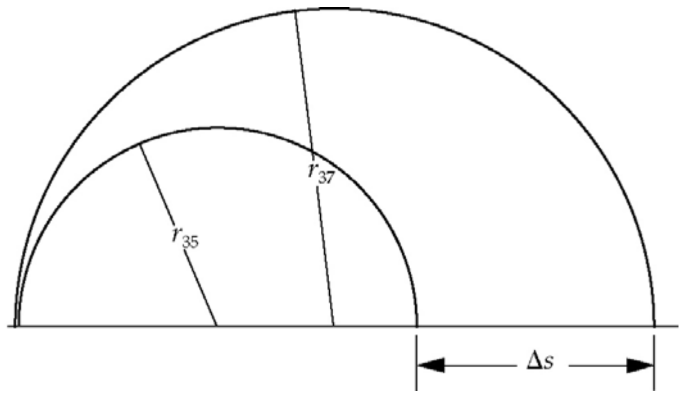
$$\Delta y = \frac{q\frac{V}{d}x_1}{m\frac{2K}{m}}\left(\frac{x_1}{2}+x_2\right) = \frac{qVx_1}{2dK}\left(\frac{x_1}{2}+x_2\right)$$

Substitute numerical values and evaluate Δy:

$$\Delta y = \frac{(1.602\times10^{-19}\ \text{C})(25.0\ \text{V})(6.00\,\text{cm})}{2(1.20\ \text{cm})(2.80\ \text{keV})}\left(\frac{6.00\,\text{cm}}{2}+30.0\,\text{cm}\right) = \boxed{7.37\,\text{mm}}$$

38 •• Chlorine has two stable isotopes, ^{35}Cl and ^{37}Cl. Chlorine gas which consists of singly-ionized ions is to be separated into its isotopic components using a mass spectrometer. The magnetic field strength in the spectrometer is 1.2 T. What is the minimum value of the potential difference through which these ions must be accelerated so that the separation between them, after they complete their semicircular path, is 1.4 cm?

Picture the Problem The diagram below represents the paths of the two ions entering the magnetic field at the left. The magnetic force acting on each causes them to travel in circular paths of differing radii due to their different masses. We can apply Newton's second law to an ion in the magnetic field to obtain an expression for its radius and then express their final separation in terms of these radii that, in turn, depend on the energy with which the ions enter the field. We can connect their energy to the potential through which they are accelerated using the work-kinetic energy theorem and relate their separation Δs to the accelerating potential difference ΔV.



Express the separation Δs of the chlorine ions:

$$\Delta s = 2(r_{37} - r_{35}) \quad (1)$$

Apply Newton's second law to an ion in the magnetic field of the mass spectrometer:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB} \quad (2)$$

Relate the speed of an ion as it enters the magnetic field to the potential difference through which it has been accelerated:

$$q\Delta V = \tfrac{1}{2}mv^2 \Rightarrow v = \sqrt{\frac{2q\Delta V}{m}}$$

Substitute for v in equation (2) to obtain:

$$r = \frac{m}{qB}\sqrt{\frac{2q\Delta V}{m}} = \sqrt{\frac{2m\Delta V}{qB^2}}$$

Use this equation to express the radii of the paths of the two chlorine isotopes to obtain:

$$r_{35} = \sqrt{\frac{2m_{35}\Delta V}{qB^2}} \text{ and } r_{37} = \sqrt{\frac{2m_{37}\Delta V}{qB^2}}$$

Substitute for r_{35} and r_{37} in equation (1) to obtain:

$$\Delta s = 2\left(\sqrt{\frac{2m_{35}\Delta V}{qB^2}} - \sqrt{\frac{2m_{35}\Delta V}{qB^2}}\right)$$
$$= 2\left(\frac{1}{B}\sqrt{\frac{2\Delta V}{q}}\left(\sqrt{m_{37}} - \sqrt{m_{35}}\right)\right)$$

Solving for ΔV yields:

$$\Delta V = \frac{qB^2\left(\frac{\Delta s}{2}\right)^2}{2\left(\sqrt{m_{37}} - \sqrt{m_{35}}\right)^2}$$

Substitute numerical values and evaluate ΔV:

$$\Delta V = \frac{(1.602\times10^{-19}\text{ C})(1.2\text{ T})^2\left(\frac{1.4\text{ cm}}{2}\right)^2}{2\left(\sqrt{37\text{ u}}-\sqrt{35\text{ u}}\right)^2}$$

$$= \frac{5.65\times10^{-24}\text{ C}\cdot\text{T}^2\cdot\text{m}^2}{\left(\sqrt{37}-\sqrt{35}\right)^2(1.66\times10^{-27}\text{ kg})}$$

$$= \boxed{0.12\text{ MV}}$$

39 •• **[SSM]** In a mass spectrometer, a singly ionized ^{24}Mg ion has a mass equal to 3.983×10^{-26} kg and is accelerated through a 2.50-kV potential difference. It then enters a region where it is deflected by a magnetic field of 557 G. (*a*) Find the radius of curvature of the ion's orbit. (*b*) What is the difference in the orbital radii of the ^{26}Mg and ^{24}Mg ions? Assume that their mass ratio is 26:24.

Picture the Problem We can apply Newton's second law to an ion in the magnetic field to obtain an expression for r as a function of m, v, q, and B and use the work-kinetic energy theorem to express the kinetic energy in terms of the potential difference through which the ion has been accelerated. Eliminating v between these equations will allow us to express r in terms of m, q, B, and ΔV.

Apply Newton's second law to an ion in the magnetic field of the mass spectrometer:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB} \qquad (1)$$

Apply the work-kinetic energy theorem to relate the speed of an ion as it enters the magnetic field to the potential difference through which it has been accelerated:

$$q\Delta V = \tfrac{1}{2}mv^2 \Rightarrow v = \sqrt{\frac{2q\Delta V}{m}}$$

Substitute for v in equation (1) and simplify to obtain:

$$r = \frac{m}{qB}\sqrt{\frac{2q\Delta V}{m}} = \sqrt{\frac{2m\Delta V}{qB^2}} \qquad (2)$$

(*a*) Substitute numerical values and evaluate equation (2) for ^{24}Mg :

$$r_{24} = \sqrt{\frac{2(3.983\times10^{-26}\text{ kg})(2.50\text{ kV})}{(1.602\times10^{-19}\text{ C})(557\times10^{-4}\text{ T})^2}}$$

$$= \boxed{63.3\text{ cm}}$$

(*b*) Express the difference in the radii for ^{24}Mg and ^{26}Mg:

$$\Delta r = r_{26} - r_{24}$$

Substituting for r_{26} and r_{24} and simplifying yields:

$$\Delta r = \sqrt{\frac{2m_{26}\Delta V}{qB^2}} - \sqrt{\frac{2m_{24}\Delta V}{qB^2}} = \frac{1}{B}\sqrt{\frac{2\Delta V}{q}}\left(\sqrt{m_{26}} - \sqrt{m_{24}}\right)$$
$$= \frac{1}{B}\sqrt{\frac{2\Delta V}{q}}\left(\sqrt{\frac{26}{24}m_{24}} - \sqrt{m_{24}}\right) = \frac{1}{B}\sqrt{\frac{2\Delta V m_{24}}{q}}\left(\sqrt{\frac{26}{24}} - 1\right)$$

Substitute numerical values and evaluate Δr:

$$\Delta r = \frac{1}{557\times10^{-4}\ \text{T}}\sqrt{\frac{2(2.50\ \text{kV})(3.983\times10^{-26}\ \text{kg})}{1.602\times10^{-19}\ \text{C}}}\left(\sqrt{\frac{26}{24}} - 1\right) = \boxed{2.58\ \text{cm}}$$

40 •• A beam of singly ionized ^{6}Li and ^{7}Li ions passes through a velocity selector and enters a region of uniform magnetic field with a velocity that is perpendicular to the direction of the field. If the diameter of the orbit of the ^{6}Li ions is 15 cm, what is the diameter of the orbit for ^{7}Li ions? Assume their mass ratio is 7:6.

Picture the Problem We can apply Newton's second law to an ion in the magnetic field of the spectrometer to relate the diameter of its orbit to its charge, mass, velocity, and the magnetic field. If we assume that the velocity is the same for the two ions, we can then express the ratio of the two diameters as the ratio of the masses of the ions and solve for the diameter of the orbit of ^{7}Li.

Apply Newton's second law to an ion in the field of the spectrometer:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Express the diameter of the orbit:

$$d = \frac{2mv}{qB}$$

The diameters of the orbits for ^{6}Li and ^{7}Li are:

$$d_6 = \frac{2m_6 v}{qB} \text{ and } d_7 = \frac{2m_7 v}{qB}$$

Assume that the velocities of the two ions are the same and divide the 2nd of these diameters by the first to obtain:

$$\frac{d_7}{d_6} = \frac{\frac{2m_7 v}{qB}}{\frac{2m_6 v}{qB}} = \frac{m_7}{m_6}$$

Solve for and evaluate d_7:

$$d_7 = \frac{m_7}{m_6} d_6 = \frac{7}{6}(15\,\text{cm}) = \boxed{18\,\text{cm}}$$

41 •• Using Example 26- 6, determine the time required for a ^{58}Ni ion and a ^{60}Ni ion to complete the semicircular path.

Picture the Problem The time required for each of the ions to complete its semicircular paths is half its period. We can apply Newton's second law to an ion in the magnetic field of the spectrometer to obtain an expression for r as a function of the charge and mass of the ion, its velocity, and the magnetic field.

Express the time for each ion to complete its semicircular path:

$$\Delta t = \tfrac{1}{2}T = \frac{\pi r}{v}$$

Apply Newton's second law to an ion in the field of the spectrometer:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Substitute for r to obtain:

$$\Delta t = \frac{\pi m}{qB}$$

Substitute numerical values and evaluate Δt_{58} and Δt_{60}:

$$\Delta t_{58} = \frac{58\pi(1.6606\times10^{-27}\,\text{kg})}{(1.602\times10^{-19}\,\text{C})(0.120\,\text{T})} = \boxed{15.7\,\mu\text{s}}$$

and

$$\Delta t_{60} = \frac{60\pi(1.6606\times10^{-27}\,\text{kg})}{(1.602\times10^{-19}\,\text{C})(0.120\,\text{T})} = \boxed{16.3\,\mu\text{s}}$$

42 •• Before entering a mass spectrometer, ions pass through a velocity selector consisting of parallel plates that are separated by 2.0 mm and have a potential difference of 160 V. The magnetic field strength is 0.42 T in the region between the plates. The magnetic field strength in the mass spectrometer is 1.2 T. Find (*a*) the speed of the ions entering the mass spectrometer and (*b*) the difference in the diameters of the orbits of singly ionized ^{238}U and ^{235}U. The mass of a ^{235}U ion is 3.903×10^{-25} kg.

Picture the Problem We can apply a condition for equilibrium to ions passing through the velocity selector to obtain an expression relating E, B, and v that we can solve for v. We can, in turn, express E in terms of the potential difference V between the plates of the selector and their separation d. In (*b*) we can apply

Newton's second law to an ion in the bending field of the spectrometer to relate its diameter to its mass, charge, velocity, and the magnetic field.

(*a*) Apply $\sum F_y = 0$ to the ions in the crossed fields of the velocity selector to obtain:

$$F_{\text{elec}} - F_{\text{mag}} = 0$$

or

$$qE - qvB = 0 \Rightarrow v = \frac{E}{B}$$

Express the electric field between the plates of the velocity selector in terms of their separation and the potential difference across them:

$$E = \frac{V}{d}$$

Substituting for *E* yields:

$$v = \frac{V}{dB}$$

Substitute numerical values and evaluate *v*:

$$v = \frac{160\,\text{V}}{(2.0\,\text{mm})(0.42\,\text{T})} = 1.905\times10^5\ \text{m/s}$$
$$= \boxed{1.9\times10^5\ \text{m/s}}$$

(*b*) Express the difference in the diameters of the orbits of singly ionized ^{238}U and ^{235}U:

$$\Delta d = d_{238} - d_{235} \qquad (1)$$

Apply $\sum F_{\text{radial}} = ma_{\text{c}}$ to an ion in the spectrometer's magnetic field:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Express the diameter of the orbit:

$$d = \frac{2mv}{qB}$$

The diameters of the orbits for ^{238}U and ^{235}U are:

$$d_{238} = \frac{2m_{238}v}{qB} \text{ and } d_{235} = \frac{2m_{235}v}{qB}$$

Substitute in equation (1) to obtain:

$$\Delta d = \frac{2m_{238}v}{qB} - \frac{2m_{235}v}{qB}$$
$$= \frac{2v}{qB}(m_{238} - m_{235})$$

Substitute numerical values and evaluate Δd:

$$\Delta d = \frac{2\left(1.905\times10^{5}\text{ m/s}\right)\left(238\text{u}-235\text{u}\right)\left(\dfrac{1.6606\times10^{-27}\text{ kg}}{\text{u}}\right)}{\left(1.602\times10^{-19}\text{ C}\right)\left(1.2\text{T}\right)} = \boxed{1\text{cm}}$$

43 •• [SSM] A cyclotron for accelerating protons has a magnetic field strength of 1.4 T and a radius of 0.70 m. (*a*) What is the cyclotron's frequency? (*b*) Find the kinetic energy of the protons when they emerge. (*c*) How will your answers change if deuterons are used instead of protons?

Picture the Problem We can express the cyclotron frequency in terms of the maximum orbital radius and speed of the protons/deuterons. By applying Newton's second law, we can relate the radius of the particle's orbit to its speed and, hence, express the cyclotron frequency as a function of the particle's mass and charge and the cyclotron's magnetic field. In Part (*b*) we can use the definition of kinetic energy and their maximum speed to find the maximum energy of the emerging protons.

(*a*) Express the cyclotron frequency in terms of the proton's orbital speed and radius:

$$f = \frac{1}{T} = \frac{1}{2\pi r/v} = \frac{v}{2\pi r} \qquad (1)$$

Apply Newton's second law to a proton in the magnetic field of the cyclotron:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB} \qquad (2)$$

Substitute for r in equation (1) and simplify to obtain:

$$f = \frac{qBv}{2\pi mv} = \frac{qB}{2\pi m} \qquad (3)$$

Substitute numerical values and evaluate f:

$$f = \frac{\left(1.602\times10^{-19}\text{ C}\right)\left(1.4\text{T}\right)}{2\pi\left(1.673\times10^{-27}\text{ kg}\right)} = 21.3\text{MHz}$$
$$= \boxed{21\text{MHz}}$$

(*b*) Express the maximum kinetic energy of a proton:

$$K_{\text{max}} = \tfrac{1}{2}mv_{\text{max}}^2$$

From equation (2), v_{max} is given by:

$$v_{\text{max}} = \frac{qBr_{\text{max}}}{m}$$

Substitute for v_{max} and simplify to obtain:

$$K_{max} = \tfrac{1}{2}m\left(\frac{qBr_{max}}{m}\right)^2 = \tfrac{1}{2}\left(\frac{q^2B^2}{m}\right)r_{max}^2$$

Substitute numerical values and evaluate K_{max}:

$$K_{max} = \tfrac{1}{2}\left(\frac{(1.602\times10^{-19}\text{ C})^2(1.4\text{ T})^2}{1.673\times10^{-27}\text{ kg}}\right)(0.7\text{ m})^2 = 7.37\times10^{-12}\text{ J}\times\frac{1\text{ eV}}{1.602\times10^{-19}\text{ J}}$$
$$= 46.0\text{ MeV} = \boxed{46\text{ MeV}}$$

(c) From equation (3) we see that doubling m halves f:

$$f_{\text{deuterons}} = \tfrac{1}{2}f_{\text{protons}} = \boxed{11\text{MHz}}$$

From our expression for K_{max} we see that doubling m halves K:

$$K_{\text{deuterons}} = \tfrac{1}{2}K_{\text{protons}} = \boxed{23\text{ MeV}}$$

44 •• A certain cyclotron that has a magnetic field whose magnitude is 1.8 T is designed to accelerate protons to a kinetic energy of 25 MeV. (a) What is the cyclotron frequency for this cyclotron? (b) What must the minimum radius of the magnet be to achieve this energy? (c) If the alternating potential difference applied to the dees has a maximum value of 50 kV, how many revolutions must the protons make before emerging with kinetic energies of 25 MeV?

Picture the Problem We can express the cyclotron frequency in terms of the maximum orbital radius and speed of the protons be accelerated in the cyclotron. By applying Newton's second law, we can relate the radius of the proton's orbit to its speed and, hence, express the cyclotron frequency as a function of the its mass and charge and the cyclotron's magnetic field. In Part (b) we can use the definition of kinetic energy express the minimum radius required to achieve the desired emergence energy. In Part (c) we can find the number of revolutions required to achieve this emergence energy from the energy acquired during each revolution.

(a) Express the cyclotron frequency in terms of the proton's orbital speed and radius:

$$f = \frac{1}{T} = \frac{1}{2\pi r/v} = \frac{v}{2\pi r}$$

Apply Newton's second law to a proton in the magnetic field of the cyclotron:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB} \qquad (1)$$

Substitute for v and simplify to obtain:

$$f=\frac{qBv}{2\pi mv}=\frac{qB}{2\pi m}$$

Substitute numerical values and evaluate f:

$$f=\frac{\left(1.602\times10^{-19}\text{ C}\right)\left(1.8\text{ T}\right)}{2\pi\left(1.673\times10^{-27}\text{ kg}\right)}$$
$$=\boxed{27\text{ MHz}}$$

(b) Using the definition of kinetic energy, relate emergence energy of the protons to their velocity:

$$K=\tfrac{1}{2}mv^2\Rightarrow v=\sqrt{\frac{2K}{m}}$$

Substitute for v in equation (1) and simplify to obtain:

$$r=\frac{m}{qB}\sqrt{\frac{2K}{m}}=\frac{\sqrt{2Km}}{qB}$$

Substitute numerical values and evaluate r_{min}:

$$r=\frac{\sqrt{2\left(25\text{ MeV}\right)\left(1.673\times10^{-27}\text{ kg}\right)}}{\left(1.602\times10^{-19}\text{ C}\right)\left(1.8\text{ T}\right)}$$
$$=\boxed{40\text{ cm}}$$

(c) Express the required number of revolutions N in terms of the energy gained per revolution:

$$N=\frac{25\text{ MeV}}{E_{\text{rev}}}$$

Because the beam is accelerated through a potential difference of 50 kV twice during each revolution:

$$E_{\text{rev}}=2q\Delta V=100\text{ keV}$$

Substitute the numerical value of E_{rev} and evaluate N:

$$N=\frac{25\text{ MeV}}{100\text{ keV/rev}}=\boxed{2.5\times10^{2}\text{ rev}}$$

45 •• Show that for a given cyclotron the cyclotron frequency for accelerating deuterons is the same as the frequency for accelerating alpha particles is half the frequency for accelerating protons in the same magnetic field. The deuteron has a charge that is equal to the charge a proton has, and an alpha particle has a charge that is equal to twice the charge a proton has. Assume that $m_\alpha = 2m_{\text{d}} = 4m_{\text{p}}$.

Picture the Problem We can express the cyclotron frequency in terms of the maximum orbital radius and speed of a particle being accelerated in the cyclotron. By applying Newton's second law, we can relate the radius of the particle's orbit

to its speed and, hence, express the cyclotron frequency as a function of its charge-to-mass ratio and the cyclotron's magnetic field. We can then use data for the relative charges and masses of deuterons, alpha particles, and protons to establish the ratios of their cyclotron frequencies.

Express the cyclotron frequency in terms of a particle's orbital speed and radius:

$$f = \frac{1}{T} = \frac{1}{2\pi r/v} = \frac{v}{2\pi r}$$

Apply Newton's second law to a particle in the magnetic field of the cyclotron:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Substitute for r to obtain:

$$f = \frac{qBv}{2\pi mv} = \frac{B}{2\pi}\frac{q}{m} \qquad (1)$$

Evaluate equation (1) for deuterons:

$$f_{\mathrm{d}} = \frac{B}{2\pi}\frac{q_{\mathrm{d}}}{m_{\mathrm{d}}} = \frac{B}{2\pi}\frac{e}{m_{\mathrm{d}}}$$

Evaluate equation (1) for alpha particles:

$$f_\alpha = \frac{B}{2\pi}\frac{q_\alpha}{m_\alpha} = \frac{B}{2\pi}\frac{2e}{2m_{\mathrm{d}}} = \frac{B}{2\pi}\frac{e}{m_{\mathrm{d}}}$$

and

$$\boxed{f_{\mathrm{d}} = f_\alpha}$$

Evaluate equation (1) for protons:

$$f_{\mathrm{p}} = \frac{B}{2\pi}\frac{q_{\mathrm{p}}}{m_{\mathrm{p}}} = \frac{B}{2\pi}\frac{e}{\frac{1}{2}m_{\mathrm{d}}} = 2\left(\frac{B}{2\pi}\frac{e}{m_{\mathrm{d}}}\right)$$

$$= 2f_{\mathrm{d}}$$

and

$$\tfrac{1}{2}f_{\mathrm{p}} = \boxed{f_{\mathrm{d}} = f_\alpha}$$

46 ••• Show that the radius of the orbit of a charged particle in a cyclotron is proportional to the square root of the number of orbits completed.

Picture the Problem We can apply Newton's second law to the orbiting charged particle to obtain an expression for its radius as a function of its particle's kinetic energy. Because the energy gain per revolution is constant, we can express this kinetic energy as the product of the number of orbits completed and the energy gained per revolution and, hence, show that the radius is proportional to the square root of the number of orbits completed.

Apply Newton's second law to a particle in the magnetic field of the cyclotron:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB} \qquad (1)$$

Express the kinetic energy of the particle in terms of its speed and solve for v:

$$K = \tfrac{1}{2}mv^2 \Rightarrow v = \sqrt{\frac{2K}{m}} \qquad (2)$$

Noting that the energy gain per revolution is constant, express the kinetic energy in terms of the number of orbits N completed by the particle and energy E_{rev} gained by the particle each revolution:

$$K = NE_{\text{rev}} \qquad (3)$$

Substitute equations (2) and (3) in equation (1) to obtain:

$$r = \frac{m}{qB}\sqrt{\frac{2K}{m}} = \frac{1}{qB}\sqrt{2mK}$$
$$= \frac{1}{qB}\sqrt{2mNE_{\text{rev}}} = \frac{\sqrt{2mE_{\text{rev}}}}{qB}N^{1/2}$$
or $\boxed{r \propto N^{1/2}}$

Torques on Current Loops, Magnets, and Magnetic Moments

47 • [SSM] A small circular coil consisting of 20 turns of wire lies in a region with a uniform magnetic field whose magnitude is 0.50 T. The arrangement is such that the normal to the plane of the coil makes an angle of 60º with the direction of the magnetic field. The radius of the coil is 4.0 cm, and the wire carries a current of 3.0 A. (*a*) What is the magnitude of the magnetic moment of the coil? (*b*) What is the magnitude of the torque exerted on the coil?

Picture the Problem We can use the definition of the magnetic moment of a coil to evaluate μ and the expression for the torque exerted on the coil $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$ to find the magnitude of τ.

(*a*) Using its definition, express the magnetic moment of the coil:

$$\mu = NIA = NI\pi r^2$$

Substitute numerical values and evaluate μ:

$$\mu = (20)(3.0\,\text{A})\pi(0.040\,\text{m})^2$$
$$= 0.302\,\text{A}\cdot\text{m}^2 = \boxed{0.30\,\text{A}\cdot\text{m}^2}$$

(*b*) Express the magnitude of the torque exerted on the coil:

$$\tau = \mu B \sin\theta$$

Substitute numerical values and evaluate τ:

$$\tau = \left(0.302\,\mathrm{A\cdot m^2}\right)\left(0.50\,\mathrm{T}\right)\sin 60° = \boxed{0.13\,\mathrm{N\cdot m}}$$

48 • What is the maximum torque on a 400-turn circular coil of radius 0.75 cm that carries a current of 1.6 mA and is in a region with a uniform magnetic field of 0.25 T?

Picture the Problem The coil will experience the maximum torque when the plane of the coil makes an angle of 90° with the direction of $\vec{B}$. The magnitude of the maximum torque is then given by $\tau_{\max} = \mu B$.

The maximum torque acting on the coil is:

$$\tau_{\max} = \mu B$$

Use its definition to express the magnetic moment of the coil:

$$\mu = NIA = NI\pi r^2$$

Substitute to obtain:

$$\tau_{\max} = NI\pi r^2 B$$

Substitute numerical values and evaluate τ:

$$\tau_{\max} = (400)(1.6\,\mathrm{mA})\pi(0.75\,\mathrm{cm})^2(0.25\,\mathrm{T}) = \boxed{28\,\mu\mathrm{N\cdot m}}$$

49 • **[SSM]** A current-carrying wire is in the shape of a square of edge-length 6.0 cm. The square lies in the $z = 0$ plane. The wire carries a current of 2.5 A. What is the magnitude of the torque on the wire if it is in a region with a uniform magnetic field of magnitude 0.30 T that points in the (*a*) +*z* direction and (*b*) +*x* direction?

Picture the Problem We can use $\vec{\tau} = \vec{\mu}\times\vec{B}$ to find the torque on the coil in the two orientations of the magnetic field.

Express the torque acting on the coil:

$$\vec{\tau} = \vec{\mu}\times\vec{B}$$

Express the magnetic moment of the coil:

$$\vec{\mu} = \pm IA\hat{k} = \pm IL^2\hat{k}$$

(*a*) Evaluate $\vec{\tau}$ for $\vec{B}$ in the $+z$ direction:

$$\vec{\tau} = \pm IL^2\hat{k}\times B\hat{k} = \pm IL^2B\left(\hat{k}\times\hat{k}\right) = \boxed{0}$$

(*b*) Evaluate $\vec{\tau}$ for $\vec{B}$ in the $+x$ direction:

$$\vec{\tau} = \pm IL^2\hat{k}\times B\hat{i} = \pm IL^2B\left(\hat{k}\times\hat{i}\right)$$
$$= \pm(2.5\,\text{A})(0.060\,\text{m})^2(0.30\,\text{T})\hat{j}$$
$$= \pm(2.7\,\text{mN}\cdot\text{m})\hat{j}$$

and

$$\left|\vec{\tau}\right| = \boxed{2.7\times10^{-3}\,\text{N}\cdot\text{m}}$$

50 • A current-carrying wire is in the shape of an equilateral triangle of edge-length 8.0 cm. The triangle lies in the $z = 0$ plane. The wire carries a current of 2.5 A. What is the magnitude of the torque on the wire if it is in a region with a uniform magnetic field of magnitude 0.30 T that points in the (*a*) $+z$ direction and (*b*) $+x$ direction?

Picture the Problem We can use $\vec{\tau} = \vec{\mu}\times\vec{B}$ to find the torque on the equilateral triangle in the two orientations of the magnetic field.

Express the torque acting on the coil:

$$\vec{\tau} = \vec{\mu}\times\vec{B}$$

Express the magnetic moment of the coil:

$$\vec{\mu} = \pm IA\hat{k}$$

Relate the area of the equilateral triangle to the length of its side:

$$A = \tfrac{1}{2}\,\text{base}\times\text{altitude}$$
$$= \frac{1}{2}(L)\left(\frac{\sqrt{3}L}{2}\right) = \frac{\sqrt{3}}{4}L^2$$

Substitute to obtain:

$$\vec{\mu} = \pm\frac{\sqrt{3}L^2I}{4}\hat{k}$$

(*a*) Evaluate $\vec{\tau}$ for $\vec{B}$ in the $+z$ direction:

$$\vec{\tau} = \pm\frac{\sqrt{3}L^2I}{4}\hat{k}\times B\hat{k}$$
$$= \pm\frac{\sqrt{3}L^2IB}{4}\left(\hat{k}\times\hat{k}\right) = \boxed{0}$$

(*b*) Evaluate $\vec{\boldsymbol{\tau}}$ for $\vec{\boldsymbol{B}}$ in the $+x$ direction:

$$\vec{\boldsymbol{\tau}} = \pm\frac{\sqrt{3}L^2 I}{4}\hat{\boldsymbol{k}}\times B\hat{\boldsymbol{i}} = \pm\frac{\sqrt{3}L^2 IB}{4}\left(\hat{\boldsymbol{k}}\times\hat{\boldsymbol{i}}\right)$$

$$= \pm\frac{\sqrt{3}(0.080\,\text{m})^2(2.5\,\text{A})(0.30\,\text{T})}{4}\hat{\boldsymbol{j}}$$

$$= \pm\left(2.1\times10^{-3}\ \text{N}\cdot\text{m}\right)\hat{\boldsymbol{j}}$$

and

$$\left|\vec{\boldsymbol{\tau}}\right| = \boxed{2.1\times10^{-3}\ \text{N}\cdot\text{m}}$$

51 •• A rigid wire is in the shape of a square of edge-length L. The square has mass m and the wire carries current I. The square lies on flat horizontal surface in a region where there is a magnetic field of magnitude B that is parallel to two edges of the square. What is the minimum value of B so that one edge of the square will lift off the surface?

Picture the Problem One edge of the square will lift off the surface when the magnitude of the magnetic torque acting on it equals the magnitude of the gravitational torque acting on it.

The condition for liftoff is that the magnitudes of the torques must be equal:

$$\tau_{\text{mag}} = \tau_{\text{grav}} \qquad (1)$$

Express the magnetic torque acting on the square:

$$\tau_{\text{mag}} = \mu B = IL^2 B$$

Express the gravitational torque acting on one edge of the square:

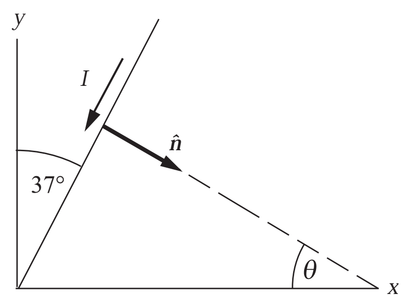
$$\tau_{\text{grav}} = mgL$$

Substituting in equation (1) yields:

$$IL^2 B_{\text{min}} = mgL \Rightarrow B_{\text{min}} = \boxed{\frac{mg}{IL}}$$

52 •• A rectangular current-carrying 50-turn coil, as shown in Figure 26-36, is pivoted about the z axis. (*a*) If the wires in the $z = 0$ plane make an angle $\theta = 37°$ with the y axis, what angle does the magnetic moment of the coil make with the unit vector $\hat{\boldsymbol{i}}$? (*b*) Write an expression for $\hat{\boldsymbol{n}}$ in terms of the unit vectors $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$, where $\hat{\boldsymbol{n}}$ is a unit vector in the direction of the magnetic moment. (*c*) What is the magnetic moment of the coil? (*d*) Find the torque on the coil when there is a uniform magnetic field $\vec{\boldsymbol{B}} = 1.5\ \text{T}\hat{\boldsymbol{j}}$ in the region occupied by the coil. (*e*) Find the potential energy of the coil in this field. (The potential energy is zero when $\theta = 0$.)

Picture the Problem The diagram shows the coil as it would appear from along the positive z axis. The right-hand rule for determining the direction of $\hat{\boldsymbol{n}}$ has been used to establish $\hat{\boldsymbol{n}}$ as shown. We can use the geometry of this figure to determine θ and to express the unit normal vector $\hat{\boldsymbol{n}}$. The magnetic moment of the coil is given by $\vec{\boldsymbol{\mu}} = NIA\hat{\boldsymbol{n}}$ and the torque exerted on the coil by $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$. Finally, we can find the potential energy of the coil in this field from $U = -\vec{\boldsymbol{\mu}} \cdot \vec{\boldsymbol{B}}$.



(*a*) Noting that θ and the angle whose measure is 37° have their right and left sides mutually perpendicular, we can conclude that:

$$\theta = \boxed{37°}$$

(*b*) Use the components of $\hat{\boldsymbol{n}}$ to express $\hat{\boldsymbol{n}}$ in terms of $\hat{\boldsymbol{i}}$ and $\hat{\boldsymbol{j}}$:

$$\hat{\boldsymbol{n}} = n_x\hat{\boldsymbol{i}} + n_y\hat{\boldsymbol{j}} = \cos 37°\hat{\boldsymbol{i}} - \sin 37°\hat{\boldsymbol{j}}$$
$$= 0.799\hat{\boldsymbol{i}} - 0.602\hat{\mathbf{j}}$$
$$= \boxed{0.80\hat{\boldsymbol{i}} - 0.60\hat{\boldsymbol{j}}}$$

(*c*) Express the magnetic moment of the coil:

$$\vec{\boldsymbol{\mu}} = NIA\hat{\boldsymbol{n}}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{\mu}}$:

$$\vec{\boldsymbol{\mu}} = (50)(1.75\,\text{A})(48.0\,\text{cm}^2)(0.799\hat{\boldsymbol{i}} - 0.602\hat{\boldsymbol{j}}) = (0.335\,\text{A}\cdot\text{m}^2)\,\hat{\boldsymbol{i}} - (0.253\,\text{A}\cdot\text{m}^2)\hat{\boldsymbol{j}}$$
$$= \boxed{(0.34\,\text{A}\cdot\text{m}^2)\,\hat{\boldsymbol{i}} - (0.25\,\text{A}\cdot\text{m}^2)\hat{\boldsymbol{j}}}$$

(*d*) Express the torque exerted on the coil:

$$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$$

Substitute for $\vec{\mu}$ and $\vec{B}$ to obtain:

$$\begin{aligned}\vec{\tau} &= \left\{\left(0.335\,\text{A}\cdot\text{m}^2\right)\hat{i} - \left(0.253\,\text{A}\cdot\text{m}^2\right)\hat{j}\right\}\times\left(1.5\,\text{T}\right)\hat{j} \\ &= \left(0.503\,\text{N}\cdot\text{m}\right)\left(\hat{i}\times\hat{j}\right) - \left(0.379\,\text{N}\cdot\text{m}\right)\left(\hat{j}\times\hat{j}\right) = \boxed{\left(0.50\,\text{N}\cdot\text{m}\right)\hat{k}}\end{aligned}$$

(*e*) Express the potential energy of the coil in terms of its magnetic moment and the magnetic field:

$$U = -\vec{\mu}\cdot\vec{B}$$

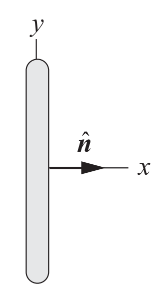
Substitute for $\vec{\mu}$ and $\vec{B}$ and evaluate U:

$$\begin{aligned}U &= -\left\{\left(0.335\,\text{A}\cdot\text{m}^2\right)\hat{i} - \left(0.253\,\text{A}\cdot\text{m}^2\right)\hat{j}\right\}\cdot\left(1.5\,\text{T}\right)\hat{j} \\ &= -\left(0.503\,\text{N}\cdot\text{m}\right)\left(\hat{i}\cdot\hat{j}\right) + \left(0.379\,\text{N}\cdot\text{m}\right)\left(\hat{j}\cdot\hat{j}\right) = \boxed{0.38\,\text{J}}\end{aligned}$$

53 •• **[SSM]** For the coil in Problem 52 the magnetic field is now $\vec{B} = 2.0\text{ T}\hat{j}$. Find the torque exerted on the coil when $\hat{n}$ is equal to (*a*) $\hat{i}$, (*b*) $\hat{j}$, (*c*) $-\hat{j}$, and (*d*) $\dfrac{\hat{i}}{\sqrt{2}} + \dfrac{\hat{j}}{\sqrt{2}}$.

Picture the Problem We can use the right-hand rule for determining the direction of $\hat{n}$ to establish the orientation of the coil for value of $\hat{n}$ and $\vec{\tau} = \vec{\mu}\times\vec{B}$ to find the torque exerted on the coil in each orientation.

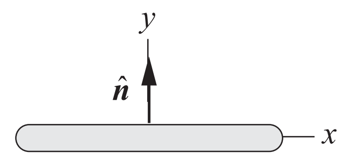
(*a*) The orientation of the coil is shown to the right:



Evaluate $\vec{\tau}$ for $\vec{B} = 2.0\text{ T}\hat{j}$ and $\hat{n} = \hat{i}$:

$$\begin{aligned}\vec{\tau} &= \vec{\mu}\times\vec{B} = NIA\hat{n}\times\vec{B} \\ &= (50)(1.75\,\text{A})\left(48.0\,\text{cm}^2\right)\hat{i}\times(2.0\,\text{T})\hat{j} \\ &= \left(0.840\,\text{N}\cdot\text{m}\right)\left(\hat{i}\times\hat{j}\right) = \left(0.840\,\text{N}\cdot\text{m}\right)\hat{k} \\ &= \boxed{\left(0.84\,\text{N}\cdot\text{m}\right)\hat{k}}\end{aligned}$$

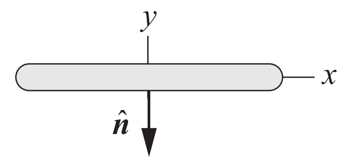
(b) The orientation of the coil is shown to the right:



Evaluate $\vec{\tau}$ for $\vec{B} = 2.0\text{ T}\,\hat{j}$ and $\hat{n} = \hat{j}$:

$$\begin{aligned}\vec{\tau} &= \vec{\mu}\times\vec{B} = NIA\hat{n}\times\vec{B}\\ &= (50)(1.75\text{ A})(48.0\text{ cm}^2)\hat{j}\times(2.0\text{ T})\hat{j}\\ &= (0.840\text{ N}\cdot\text{m})(\hat{j}\times\hat{j})\\ &= \boxed{0}\end{aligned}$$

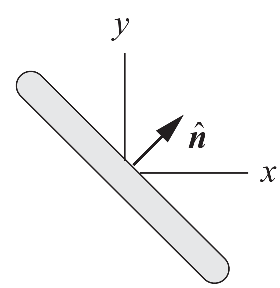
(c) The orientation of the coil is shown to the right:



Evaluate $\vec{\tau}$ for $\vec{B} = 2.0\text{ T}\,\hat{j}$ and $\hat{n} = -\hat{j}$:

$$\begin{aligned}\vec{\tau} &= \vec{\mu}\times\vec{B} = NIA\hat{n}\times\vec{B}\\ &= -(50)(1.75\text{ A})(48.0\text{ cm}^2)\hat{j}\times(2.0\text{ T})\hat{j}\\ &= (-0.840\text{ N}\cdot\text{m})(\hat{j}\times\hat{j})\\ &= \boxed{0}\end{aligned}$$

(d) The orientation of the coil is shown to the right:



Evaluate $\vec{\tau}$ for $\vec{B} = 2.0\text{ T}\,\hat{j}$ and $\hat{n} = (\hat{i}+\hat{j})/\sqrt{2}$:

$$\begin{aligned}\vec{\tau} &= \vec{\mu}\times\vec{B} = NIA\hat{n}\times\vec{B}\\ &= \frac{(50)(1.75\text{ A})(48.0\text{ cm}^2)}{\sqrt{2}}(\hat{i}+\hat{j})\times(2.0\text{ T})\hat{j}\\ &= (0.594\text{ N}\cdot\text{m})(\hat{i}\times\hat{j})\\ &\quad+(0.594\text{ N}\cdot\text{m})(\hat{j}\times\hat{j})\\ &= \boxed{(0.59\text{ N}\cdot\text{m})\hat{k}}\end{aligned}$$

54 •• A small bar magnet has a length equal to 6.8 cm and its magnetic moment is aligned with a uniform magnetic field of magnitude 0.040 T. The bar magnet is then rotated through an angle of 60 about an axis perpendicular to its length The observed torque on the bar magnet has a magnitude of 0.10 N·m.

(*a*) Find the magnetic moment of the magnet. (*b*) Find the potential energy of the magnet.

Picture the Problem Because the small magnet can be modeled as a magnetic dipole; we can use the equation for the torque on a current loop to find its magnetic moment.

(*a*) Express the magnitude of the torque acting on the magnet:

$$\tau = \mu B \sin\theta$$

Solve for μ to obtain:

$$\mu = \frac{\tau}{B\sin\theta}$$

Substitute numerical values and evaluate μ:

$$\mu = \frac{0.10\,\text{N}\cdot\text{m}}{(0.040\,\text{T})\sin 60^\circ} = \boxed{2.9\,\text{A}\cdot\text{m}^2}$$

(*b*) The potential energy of the magnet is given by:

$$U = -\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}} = -\mu B\cos\theta$$

Substitute numerical values and evaluate U:

$$U = -\left(2.887\,\text{A}\cdot\text{m}^2\right)(0.040\,\text{T})\cos 60^\circ = \boxed{-58\,\text{mJ}}$$

55 •• A wire loop consists of two semicircles connected by straight segments (Figure 26-37). The inner and outer radii are 0.30 m and 0.50 m, respectively. A current of 1.5 A is in this wire and the current in the outer semicircle is in the clockwise direction. What is the magnetic moment of this current loop?

Picture the Problem We can use the definition of the magnetic moment to find the magnetic moment of the given current loop and a right-hand rule to find its direction.

Using its definition, express the magnetic moment of the current loop:

$$\mu = IA$$

Express the area bounded by the loop:

$$A = \tfrac{1}{2}\left(\pi R_{\text{outer}}^2 - \pi R_{\text{inner}}^2\right) = \frac{\pi}{2}\left(R_{\text{outer}}^2 - R_{\text{inner}}^2\right)$$

Substitute for A to obtain:

$$\mu = \frac{\pi I}{2}\left(R_{\text{outer}}^2 - R_{\text{inner}}^2\right)$$

Substitute numerical values and evaluate μ:

$$\mu = \frac{\pi(1.5\,\text{A})}{2}\left[(0.50\,\text{m})^2 - (0.30\,\text{m})^2\right] = \boxed{0.38\,\text{A}\cdot\text{m}^2}$$

Apply the right-hand rule for determining the direction of the unit normal vector (the direction of μ) to conclude that $\vec{\boldsymbol{\mu}}$ points into the page.

56 •• A wire of length L is wound into a circular coil that has N turns. Show that when the wire carries a current I, the magnetic moment of the coil has a magnitude given by $IL^2/(4\pi N)$.

Picture the Problem We can use the definition of the magnetic moment of a coil to find the magnetic moment of a wire of length L that is wound into a circular coil of N loops. We can find the area of the coil from its radius R and we can find R by dividing the length of the wire by the number of turns.

Use its definition to express the magnetic moment of the coil:

$$\mu = NIA \qquad (1)$$

Express the circumference of each loop:

$$\frac{L}{N} = 2\pi R \Rightarrow R = \frac{L}{2\pi N}$$

where R is the radius of a loop.

The area of the coil is given by:

$$A = \pi R^2$$

Substituting for A and simplifying yields:

$$A = \pi\left(\frac{L}{2\pi N}\right)^2 = \frac{L^2}{4\pi N^2}$$

Substitute for A in equation (1) and simplify to obtain:

$$\mu = NI\left(\frac{L^2}{4\pi N^2}\right) = \boxed{\frac{IL^2}{4\pi N}}$$

57 •• **[SSM]** A particle that has a charge q and a mass m moves with angular velocity ω in a circular path of radius r. (a) Show that the average current created by this moving particle is $\omega q/(2\pi)$ and that the magnetic moment of its orbit has a magnitude of $\frac{1}{2}q\omega r^2$. (b) Show that the angular momentum of this particle has the magnitude of $mr^2\omega$ and that the magnetic moment and angular momentum vectors are related by $\vec{\boldsymbol{\mu}} = \left(\frac{q}{2m}\right)\vec{\boldsymbol{L}}$, where $\vec{\boldsymbol{L}}$ is the angular momentum about the center of the circle.

Picture the Problem We can use the definition of current and the relationship between the frequency of the motion and its period to show that $I = q\omega/2\pi$. We can use the definition of angular momentum and the moment of inertia of a point particle to show that the magnetic moment has the magnitude $\mu = \frac{1}{2}q\omega r^2$. Finally, we can express the ratio of μ to L and the fact that $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{L}}$ are both parallel to $\vec{\boldsymbol{\omega}}$ to conclude that $\vec{\boldsymbol{\mu}} = (q/2m)\vec{\boldsymbol{L}}$.

(*a*) Using its definition, relate the average current to the charge passing a point on the circumference of the circle in a given period of time:

$$I = \frac{\Delta q}{\Delta t} = \frac{q}{T} = qf$$

Relate the frequency of the motion to the angular frequency of the particle:

$$f = \frac{\omega}{2\pi}$$

Substitute for f to obtain:

$$I = \boxed{\frac{q\omega}{2\pi}}$$

From the definition of the magnetic moment we have:

$$\mu = IA = \left(\frac{q\omega}{2\pi}\right)\left(\pi r^2\right) = \boxed{\tfrac{1}{2}q\omega r^2}$$

(*b*) Express the angular momentum of the particle:

$$L = I\omega$$

The moment of inertia of the particle is:

$$I = mr^2$$

Substituting for I yields:

$$L = \left(mr^2\right)\omega = \boxed{mr^2\omega}$$

Express the ratio of μ to L and simplify to obtain:

$$\frac{\mu}{L} = \frac{\frac{1}{2}q\omega r^2}{mr^2\omega} = \frac{q}{2m} \Rightarrow \mu = \frac{q}{2m}L$$

Because $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{L}}$ are both parallel to $\vec{\boldsymbol{\omega}}$:

$$\vec{\boldsymbol{\mu}} = \boxed{\left(\frac{q}{2m}\right)\vec{\boldsymbol{L}}}$$

58 ••• A hollow non-conducting cylinder has length L and inner and outer radii R_i A uniformly charged non-conducting cylindrical shell (Figure 26-38) has length L, inner and outer radii R_i and R_o, respectively, a charge density ρ and an

angular velocity ω about its axis. Derive an expression for the magnetic moment of the cylinder.

Picture the Problem We can express the magnetic moment of an element of charge dq in a cylinder of length L, radius r, and thickness dr, relate this charge to the length, radius, and thickness of the cylinder, express the current due to this rotating charge, substitute for A and dI in our expression for μ and then integrate to complete our derivation for the magnetic moment of the rotating cylinder as a function of its angular velocity.

Express the magnetic moment of an element of charge dq in a cylinder of length L, radius r, and thickness dr:

$$d\mu = AdI = \pi r^2 dI \qquad (1)$$

Relate the charge dq in the cylinder to the length of the cylinder, its radius, and thickness:

$$dq = 2\pi L\rho r dr$$

The current due to this rotating charge is given by:

$$dI = \frac{\omega}{2\pi}dq = \frac{\omega}{2\pi}(2\pi L\rho r dr) = L\rho r\omega dr$$

Substitute for dI in equation (1) and simplify to obtain:

$$d\mu = \pi r^2(L\rho\omega r dr) = L\rho\pi\omega r^3 dr$$

Integrate r from R_i to R_0 to obtain:

$$\mu = L\rho\pi\omega\int_{R_\text{i}}^{R_0} r^3 dr = \tfrac{1}{4}L\rho\pi\omega\left(R_0^4 - R_\text{i}^4\right)$$

Because $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{\omega}}$ are parallel:

$$\vec{\boldsymbol{\mu}} = \boxed{\tfrac{1}{4}L\rho\pi\left(R_0^4 - R_\text{i}^4\right)\vec{\boldsymbol{\omega}}}$$

59 ••• [SSM] A uniform non-conducting thin rod of mass m and length L has a uniform charge per unit length λ and rotates with angular speed ω about an axis through one end and perpendicular to the rod. (*a*) Consider a small segment of the rod of length dx and charge $dq = \lambda dr$ at a distance r from the pivot (Figure 26-40). Show that the average current created by this moving segment is $\omega dq/(2\pi)$ and show that the magnetic moment of this segment is $\frac{1}{2}\lambda\omega r^2 dx$. (*b*) Use this to show that the magnitude of the magnetic moment of the rod is $\frac{1}{6}\lambda\omega L^3$. (*c*) Show that the magnetic moment $\vec{\boldsymbol{\mu}}$ and angular momentum $\vec{\boldsymbol{L}}$ are related by $\vec{\boldsymbol{\mu}} = \left(\dfrac{Q}{2m}\right)\vec{\boldsymbol{L}}$, where Q is the total charge on the rod.

Picture the Problem We can follow the step-by-step outline provided in the problem statement to establish the given results.

(*a*) Express the magnetic moment of the rotating element of charge:

$$d\mu = A\,dI \qquad (1)$$

The area enclosed by the rotating element of charge is:

$$A = \pi x^2$$

Express dI in terms of dq and Δt:

$$dI = \frac{dq}{\Delta t} = \frac{\lambda dx}{\Delta t}$$ where Δt is the time required for one revolution.

The time Δt required for one revolution is:

$$\Delta t = \frac{1}{f} = \frac{2\pi}{\omega}$$

Substitute for Δt and simplify to obtain:

$$dI = \frac{\lambda\omega}{2\pi}dx$$

Substituting for dI in equation (1) and simplifying yields:

$$d\mu = \left(\pi x^2\right)\left(\frac{\lambda\omega}{2\pi}dx\right) = \boxed{\tfrac{1}{2}\lambda\omega x^2 dx}$$

(*b*) Integrate $d\mu$ from $x = 0$ to $x = L$ to obtain:

$$\mu = \tfrac{1}{2}\lambda\omega\int_0^L x^2 dx = \boxed{\tfrac{1}{6}\lambda\omega L^3}$$

(*c*) Express the angular momentum of the rod:

$$L = I\omega$$

where L is the angular momentum of the rod and I is the moment of inertia of the rod with respect to the point about which it is rotating.

Express the moment of inertia of the rod with respect to an axis through its end:

$$I = \tfrac{1}{3}mL^2$$

where L is now the length of the rod.

Substitute for I to obtain:

$$L = \tfrac{1}{3}mL^2\omega$$

Divide the expression for μ by L to obtain:

$$\frac{\mu}{L}=\frac{\frac{1}{6}\lambda\omega L^3}{\frac{1}{3}mL^2\omega}=\frac{\lambda L}{2m}$$

or, because $Q = \lambda L$,

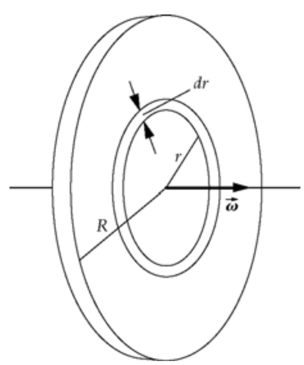
$$\mu=\frac{Q}{2m}L$$

Because $\vec{\omega}$ and $\vec{L} = I\vec{\omega}$ are parallel:

$$\vec{\mu}=\boxed{\left(\frac{Q}{2M}\right)\vec{L}}$$

60 ••• A non-uniform, non-conducting thin disk of mass m, radius R, and total charge Q has a charge per unit area σ that varies as $\sigma_0 r/R$ and a mass per unit area σ_m that is given by $(m/Q)\,\sigma$. The disk rotates with angular speed ω about its central axis. (*a*) Show that the magnetic moment of the disk has a magnitude $\frac{1}{5}\pi\omega\sigma_0 R^4$ which can be alternatively rewritten as $\frac{3}{10}\omega QR^2$. (*b*) Show that the magnetic moment $\vec{\mu}$ and angular momentum $\vec{L}$ are related by $\vec{\mu}=\frac{Q}{2M}\vec{L}$.

Picture the Problem We can express the magnetic moment of an element of current dI due to a ring of radius r, and thickness dr with charge dq. Integrating this expression from $r = 0$ to $r = R$ will give us the magnetic moment of the disk. We can integrate the charge on the ring between these same limits to find the total charge on the disk and divide μ by Q to establish the relationship between them. In Part (*b*) we can find the angular momentum of the disk by first finding the moment of inertia of the disk by integrating r^2dm between the same limits used above.



(*a*) Express the magnetic moment of an element of the disk:

$$d\mu = AdI$$

The area enclosed by the rotating element of charge is:

$$A = \pi x^2$$

Express the element of current dI:

$$dI = \frac{dq}{\Delta t} = \frac{\sigma dA}{\Delta t} = f\sigma dA$$
$$= \frac{\omega}{2\pi}\left(\sigma_0 \frac{r}{R}\right)(2\pi\, r dr) = \frac{\sigma_0 \omega}{R} r^2 dr$$

Substitute for A and dI and simplify to obtain:

$$d\mu = \pi r^2 \frac{\sigma_0 \omega}{R} r^2 dr = \frac{\sigma_0 \pi \omega}{R} r^4 dr$$

Integrate $d\mu$ from $r = 0$ to $r = R$ to obtain:

$$\mu = \frac{\sigma_0 \pi \omega}{R} \int_0^R r^4 dr = \boxed{\tfrac{1}{5}\sigma_0 \pi \omega R^4} \qquad (1)$$

The charge dq within a distance r of the center of the disk is given by:

$$dq = 2\pi r \sigma dr = 2\pi r\left(\sigma_0 \frac{r}{R}\right)dr$$
$$= \frac{2\pi\sigma_0}{R} r^2 dr$$

Integrate dq from $r = 0$ to $r = R$ to obtain:

$$Q = \frac{2\pi\sigma_0}{R} \int_0^R r^2 dr = \tfrac{2}{3}\pi\sigma_0 R^2 \qquad (2)$$

Divide equation (1) by Q to obtain:

$$\frac{\mu}{Q} = \frac{\tfrac{1}{5}\sigma_0 \pi \omega R^4}{\tfrac{2}{3}\pi\sigma_0 R^2} = \frac{3\omega R^2}{10}$$

and

$$\mu = \boxed{\tfrac{3}{10} Q\omega R^2} \qquad (3)$$

(b) Express the moment of inertia of an element of mass dm of the disk:

$$dI = r^2 dm = r^2 \sigma_{\mathrm{m}} dA$$
$$= r^2\left(\frac{m}{Q}\sigma\right)(2\pi r dr)$$
$$= \frac{2\pi m\left(\frac{r}{R}\sigma_0\right)}{Q} r^3 dr$$
$$= \frac{2\pi m \sigma_0}{QR} r^4 dr$$

Integrate dI from $r = 0$ to $r = R$ to obtain:

$$I = \frac{2\pi m \sigma_0}{QR} \int_0^R r^4 dr = \frac{2\pi m \sigma_0}{5Q} R^4$$

Divide I by equation (2) and simplify to obtain:

$$\frac{I}{Q}=\frac{\frac{2\pi m\sigma_0}{5Q}R^4}{\frac{2}{3}\pi\sigma_0 R^2}=\frac{3m}{5Q}R^2$$

and

$$I=\frac{3m}{5}R^2$$

Express the angular momentum of the disk:

$$L=I\omega=\tfrac{3}{5}mR^2\omega$$

Divide equation (3) by L and simplify to obtain:

$$\frac{\mu}{L}=\frac{\frac{3}{10}Q\omega R^2}{\frac{3}{5}mR^2\omega}=\frac{Q}{2m}\Rightarrow\mu=\frac{Q}{2m}L$$

Because $\vec{\boldsymbol{\mu}}$ is in the same direction as $\vec{\boldsymbol{\omega}}$:

$$\vec{\boldsymbol{\mu}}=\boxed{\frac{Q}{2m}\vec{\boldsymbol{L}}}$$

61 ••• [SSM] A spherical shell of radius R carries a constant surface charge density σ. The shell rotates about its diameter with angular speed ω. Find the magnitude of the magnetic moment of the rotating shell.

Picture the Problem We can use the result of Problem 57 to express μ as a function of Q, M, and L. We can then use the definitions of surface charge density and angular momentum to substitute for Q and L to obtain the magnetic moment of the rotating shell.

Express the magnetic moment of the spherical shell in terms of its mass, charge, and angular momentum:

$$\mu=\frac{Q}{2M}L$$

Use the definition of surface charge density to express the charge on the spherical shell:

$$Q=\sigma A=4\pi\sigma R^2$$

Express the angular momentum of the spherical shell:

$$L=I\omega=\tfrac{2}{3}MR^2\omega$$

Substitute for L and simplify to obtain:

$$\mu=\left(\frac{4\pi\sigma R^2}{2M}\right)\left(\frac{2}{3}MR^2\omega\right)=\boxed{\tfrac{4}{3}\pi\sigma R^4\omega}$$

62 ••• A uniform solid uniformly charged sphere of radius R has a volume charge density ρ. The sphere rotates about an axis through its center with angular speed ω. Find the magnitude of the magnetic moment of this rotating sphere.

Picture the Problem We can use the result of Problem 57 to express μ as a function of Q, M, and L. We can then use the definitions of volume charge density and angular momentum to substitute for Q and L to obtain the magnetic moment of the rotating sphere.

Express the magnetic moment of the solid sphere in terms of its mass, charge, and angular momentum:

$$\mu = \frac{Q}{2M}L$$

Use the definition of volume charge density to express the charge of the sphere:

$$Q = \rho V = \tfrac{4}{3}\pi\rho R^3$$

Express the angular momentum of the solid sphere:

$$L = I\omega = \tfrac{2}{5}MR^2\omega$$

Substitute for Q and L and simplify to obtain:

$$\mu = \left(\frac{\tfrac{4}{3}\pi\rho R^3}{2M}\right)\left(\frac{2}{5}MR^2\omega\right) = \boxed{\tfrac{4}{15}\pi\rho R^5\omega}$$

63 ••• A uniform thin uniformly charged disk of mass m, radius R, and uniform surface charge density σ rotates with angular speed ω about an axis through its center and perpendicular to the disk (Figure 26-40). The disk in in a region with a uniform magnetic field $\vec{B}$ that makes an angle θ with the rotation axis. Calculate (*a*) the magnitude of the torque exerted on the disk by the magnetic field and (*b*) the precession frequency of the disk in the magnetic field.

Picture the Problem We can use its definition to express the torque acting on the disk, Example 26-11 to express the magnetic moment of the disk, and the definition of the precession frequency to find the precession frequency of the disk.

(*a*) The magnitude of the net torque acting on the disk is:

$$\tau = \mu B\sin\theta$$

where μ is the magnetic moment of the disk.

From Example 26-11:

$$\mu = \tfrac{1}{4}\pi\sigma r^4\omega$$

Substitute for μ in the expression for τ to obtain:

$$\tau = \boxed{\tfrac{1}{4}\pi\sigma r^4\omega B\sin\theta}$$

(*b*) The precession frequency Ω is equal to the ratio of the torque divided by the spin angular momentum:

$$\Omega = \frac{\tau}{I\omega}$$

For a solid disk, the moment of inertia is given by:

$$I = \tfrac{1}{2}mr^2$$

Substitute for τ and I to obtain:

$$\Omega = \frac{\frac{1}{4}\pi\sigma r^4 \omega B \sin\theta}{\frac{1}{2}mr^2\omega} = \boxed{\frac{\pi\sigma r^2 B}{2m}\sin\theta}$$

Remarks: Note that the precession frequency is independent of ω.

The Hall Effect

64 • A metal strip that is 2.00-cm wide and 0.100-cm thick carries a current of 20.0 A in region with a uniform magnetic field of 2.00 T, as shown in Figure 26-41. The Hall voltage is measured to be 4.27 μV. (*a*) Calculate the drift speed of the free electrons in the strip. (*b*) Find the number density of the free electrons in the strip. (*c*) Is point *a* or point *b* at the higher potential? Explain your answer.

Picture the Problem We can use the Hall effect equation to find the drift speed of the electrons and the relationship between the current and the number density of charge carriers to find *n*. In (*c*) we can use a right-hand rule to decide whether *a* or *b* is at the higher potential.

(*a*) Express the Hall voltage as a function of the drift speed of the electrons in the strip:

$$V_{\mathrm{H}} = v_{\mathrm{d}}Bw \Rightarrow v_{\mathrm{d}} = \frac{V_{\mathrm{H}}}{Bw}$$

Substitute numerical values and evaluate v_{d}:

$$v_{\mathrm{d}} = \frac{4.27\,\mu\mathrm{V}}{(2.00\,\mathrm{T})(2.00\,\mathrm{cm})} = 0.1068\,\mathrm{mm/s} = \boxed{0.107\,\mathrm{mm/s}}$$

(*b*) Express the current as a function of the number density of charge carriers:

$$I = nAqv_{\mathrm{d}} \Rightarrow n = \frac{I}{Aqv_{\mathrm{d}}}$$

Substitute numerical values and evaluate *n*:

$$n = \frac{20.0\,\mathrm{A}}{(2.00\,\mathrm{cm})(0.100\,\mathrm{cm})(1.602\times10^{-19}\,\mathrm{C})(0.1068\,\mathrm{mm/s})} = \boxed{5.85\times10^{28}\,\mathrm{m^{-3}}}$$

(c) Apply a right-hand rule to $I\vec{\ell}$ and $\vec{\boldsymbol{B}}$ to conclude that positive charge will accumulate at a and negative charge at b and therefore $\boxed{V_a > V_b}$. The Hall effect electric field is directed from a toward b.

65 •• **[SSM]** The number density of free electrons in copper is 8.47×10^{22} electrons per cubic centimeter. If the metal strip in Figure 26-41 is copper and the current is 10.0 A, find (a) the drift speed v_d and (b) the potential difference $V_a - V_b$. Assume that the magnetic field strength is 2.00 T.

Picture the Problem We can use $I = nqv_d A$ to find the drift speed and $V_H = v_d Bw$ to find the potential difference $V_a - V_b$.

(a) Express the current in the metal strip in terms of the drift speed of the electrons:

$$I = nqv_d A \Rightarrow v_d = \frac{I}{nqA}$$

Substitute numerical values and evaluate v_d:

$$v_d = \frac{10.0\,\text{A}}{\left(8.47\times10^{22}\,\text{cm}^{-3}\right)\left(1.602\times10^{-19}\,\text{C}\right)\left(2.00\,\text{cm}\right)\left(0.100\,\text{cm}\right)}$$
$$= 3.685\times10^{-5}\,\text{m/s} = \boxed{3.68\times10^{-5}\,\text{m/s}}$$

(b) The potential difference $V_a - V_b$ is the Hall voltage and is given by:

$$V_a - V_b = V_H = v_d Bw$$

Substitute numerical values and evaluate $V_a - V_b$:

$$V_a - V_b = \left(3.685\times10^{-5}\,\text{m/s}\right)\left(2.00\,\text{T}\right)\left(2.00\,\text{cm}\right) = \boxed{1.47\,\mu\text{V}}$$

66 •• A copper strip has 8.47×10^{22} free electrons per cubic centimeter is 2.00-cm wide, is 0.100-cm thick, and is used to measure the magnitudes of unknown magnetic fields that are perpendicular to it. Find the magnitude of B when the current is 20.0 A and the Hall voltage is (a) 2.00 μV, (b) 5.25 μV, and (c) 8.00 μV.

Picture the Problem We can use $V_H = v_d Bw$ to express B in terms of V_H and $I = nqv_d A$ to eliminate the drift velocity v_d and derive an expression for B in terms of V_H, n, and t.

Relate the Hall voltage to the drift velocity and the magnetic field:

$$V_H = v_d B w \Rightarrow B = \frac{V_H}{v_d w}$$

Express the current in the metal strip in terms of the drift velocity of the electrons:

$$I = nqv_d A \Rightarrow v_d = \frac{I}{nqA}$$

Substitute for v_d and simplify to obtain:

$$B = \frac{V_H}{\frac{I}{nqA}w} = \frac{nqAV_H}{Iw} = \frac{nqwtV_H}{Iw} = \frac{nqt}{I}V_H$$

Substitute numerical values and simplify to obtain:

$$B = \frac{(8.47\times10^{22}\ \text{cm}^{-3})(1.602\times10^{-19}\ \text{C})(0.100\,\text{cm})V_H}{20.0\,\text{A}} = (6.7845\times10^{5}\ \text{s/m}^2)V_H$$

(*a*) Evaluate B for $V_H = 2.00\ \mu\text{V}$:

$$B = (6.7845\times10^{5}\ \text{s/m}^2)(2.00\,\mu\text{V}) = \boxed{1.36\,\text{T}}$$

(*b*) Evaluate B for $V_H = 5.25\ \mu\text{V}$:

$$B = (6.7845\times10^{5}\ \text{s/m}^2)(5.25\,\mu\text{V}) = \boxed{3.56\,\text{T}}$$

(*c*) Evaluate B for $V_H = 8.00\ \mu\text{V}$:

$$B = (6.7845\times10^{5}\ \text{s/m}^2)(8.00\,\mu\text{V}) = \boxed{5.43\,\text{T}}$$

67 •• Because blood contains ions, moving blood in the presence of a magnetic field develops a Hall voltage across the diameter of an artery. A large artery that has a diameter of 0.85 cm can have blood flowing through it with a maximum speed of 0.60 m/s. If a section of this artery is in a magnetic field of 0.20 T, what is the maximum potential difference across the diameter of the artery?

Picture the Problem We can use $V_H = v_d B w$ to find the Hall voltage developed across the diameter of the artery.

Relate the Hall voltage to the flow speed of the blood v_d, the diameter of the artery w, and the magnetic field B:

$$V_H = v_d B w$$

Substitute numerical values and evaluate V_H:

$$V_H = (0.60\,\text{m/s})(0.20\,\text{T})(0.85\,\text{cm}) = \boxed{1.0\,\text{mV}}$$

68 •• The Hall coefficient R_H is a property of conducting material (just as resistivity is). It is defined as $R_H = E_y/(J_xB_z)$, where J_x is x component of the current density in the material, B_z is the z component of the magnetic field, and E_y is the y component resulting Hall electric field. Show that the Hall coefficient is equal to $1/(nq)$, where q is the charge of the charge carriers ($-e$ if they are electrons). (The Hall coefficients of monovalent metals, such as copper, silver, and sodium are therefore negative.)

Picture the Problem Let the width of the slab be w and its thickness t. We can use the definition of the Hall electric field in the slab, the expression for the Hall voltage across it, and the definition of current density to show that the Hall coefficient is also given by $1/(nq)$.

The Hall coefficient is:

$$R = \frac{E_y}{J_x B_z}$$

Using its definition, express the Hall electric field in the slab:

$$E_y = \frac{V_H}{w}$$

The current density in the slab is:

$$J_x = \frac{I}{wt} = nqv_d$$

Substitute for E_y and J_x and simplify to obtain:

$$R = \frac{\frac{V_H}{w}}{nqv_d B_z} = \frac{V_H}{nqv_d w B_z}$$

Express the Hall voltage in terms of v_d, B, and w:

$$V_H = v_d B_z w$$

Substitute for V_H and simplify to obtain:

$$R = \frac{v_d B_z w}{nqv_d w B_z} = \boxed{\frac{1}{nq}}$$

69 •• [SSM] Aluminum has a density of 2.7×10^3 kg/m^3 and a molar mass of 27 g/mol. The Hall coefficient of aluminum is $R = -0.30 \times 10^{-10}$ m^3/C. (See Problem 68 for the definition of R.) What is the number of conduction electrons per aluminum atom?

Picture the Problem We can determine the number of conduction electrons per atom from the quotient of the number density of charge carriers and the number of charge carriers per unit volume. Let the width of a slab of aluminum be w and its thickness t. We can use the definition of the Hall electric field in the slab, the expression for the Hall voltage across it, and the definition of current density to find n in terms of R and q and $n_a = \rho N_A / M$, to express n_a.

Express the number of electrons per atom N:

$$N = \frac{n}{n_a} \qquad (1)$$

where n is the number density of charge carriers and n_a is the number of atoms per unit volume.

From the definition of the Hall coefficient we have:

$$R = \frac{E_y}{J_x B_z}$$

Express the Hall electric field in the slab:

$$E_y = \frac{V_H}{w}$$

The current density in the slab is:

$$J_x = \frac{I}{wt} = nqv_d$$

Substitute for E_y and J_x in the expression for R to obtain:

$$R = \frac{\frac{V_H}{w}}{nqv_d B_z} = \frac{V_H}{nqv_d w B_z}$$

Express the Hall voltage in terms of v_d, B, and w:

$$V_H = v_d B_z w$$

Substitute for V_H and simplify to obtain:

$$R = \frac{v_d B_z w}{nqv_d w B_z} = \frac{1}{nq} \Rightarrow n = \frac{1}{Rq} \qquad (2)$$

Express the number of atoms n_a per unit volume:

$$n_a = \rho \frac{N_A}{M} \qquad (3)$$

Substitute equations (2) and (3) in equation (1) to obtain:

$$N=\frac{M}{qR\rho N_{\text{A}}}$$

Substitute numerical values and evaluate N:

$$N=\frac{27\,\frac{\text{g}}{\text{mol}}}{\left(-1.602\times10^{-19}\,\text{C}\right)\left(-0.30\times10^{-10}\,\frac{\text{m}^3}{\text{C}}\right)\left(2.7\times10^{3}\,\frac{\text{kg}}{\text{m}^3}\right)\left(6.022\times10^{23}\,\frac{\text{atoms}}{\text{mol}}\right)}$$
$$\approx \boxed{4}$$

General Problems

70 • A long wire parallel to the x axis carries a current of 6.50 A in the $+x$ direction. The wire occupies a region that has a uniform magnetic field $\vec{B}=1.35\text{ T}\,\hat{\boldsymbol{j}}$. Find the magnetic force per unit length on the wire.

Picture the Problem We can use the expression for the magnetic force acting on a wire ($\vec{F}=I\vec{\ell}\times\vec{B}$) to find the force per unit length on the wire.

Express the magnetic force on the wire:

$$\vec{F}=I\vec{\ell}\times\vec{B}$$

Substitute for $I\vec{\ell}$ and $\vec{B}$ to obtain:

$$\vec{F}=(6.50\,\text{A})\ell\hat{\boldsymbol{i}}\times(1.35\,\text{T})\hat{\boldsymbol{j}}$$

and

$$\frac{\vec{F}}{\ell}=(6.50\,\text{A})\hat{\boldsymbol{i}}\times(1.35\,\text{T})\hat{\boldsymbol{j}}$$

Simplify to obtain:

$$\frac{\vec{F}}{\ell}=(8.78\,\text{N/m})\left(\hat{\boldsymbol{i}}\times\hat{\boldsymbol{j}}\right)=\boxed{(8.78\,\text{N/m})\hat{\boldsymbol{k}}}$$

71 • An alpha particle (charge $+2e$) travels in a circular path of radius 0.50 m in a region with a magnetic field whose magnitude is 0.10 T. Find (*a*) the period, (*b*) the speed, and (*c*) the kinetic energy (in electron volts) of the alpha particle. (The mass of an alpha particle is 6.65×10^{-27} kg.)

Picture the Problem We can express the period of the alpha particle's motion in terms of its orbital speed and use Newton's second law to express its orbital speed in terms of known quantities. Knowing the particle's period and the radius of its motion we can find its speed and kinetic energy.

(*a*) Relate the period of the alpha particle's motion to its orbital speed:

$$T = \frac{2\pi r}{v} \qquad (1)$$

Apply Newton's second law to the alpha particle to obtain:

$$qvB = m\frac{v^2}{r} \Rightarrow v = \frac{qBr}{m}$$

Substitute for v in equation (1) and simplify to obtain:

$$T = \frac{2\pi r}{\frac{qBr}{m}} = \frac{2\pi m}{qB}$$

Substitute numerical values and evaluate T:

$$T = \frac{2\pi\left(6.65\times10^{-27}\text{ kg}\right)}{2\left(1.602\times10^{-19}\text{ C}\right)\left(0.10\text{ T}\right)} = 1.30\ \mu\text{s}$$
$$= \boxed{1.3\ \mu\text{s}}$$

(*b*) Solve equation (1) for v:

$$v = \frac{2\pi r}{T}$$

Substitute numerical values and evaluate v:

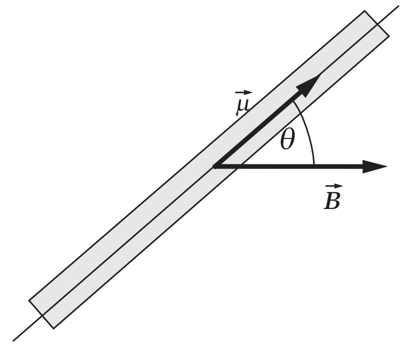
$$v = \frac{2\pi\left(0.50\text{ m}\right)}{1.30\ \mu\text{s}} = 2.409\times10^{6}\text{ m/s}$$
$$= \boxed{2.4\times10^{6}\text{ m/s}}$$

(*c*) The kinetic energy of the alpha particle is:

$$K = \tfrac{1}{2}mv^2$$
$$= \tfrac{1}{2}\left(6.65\times10^{-27}\text{ kg}\right)\left(2.409\times10^{6}\text{ m/s}\right)^2$$
$$= 1.930\times10^{-14}\text{ J}\times\frac{1\text{ eV}}{1.602\times10^{-19}\text{ J}}$$
$$= \boxed{0.12\text{ MeV}}$$

72 •• The pole strength q_m of a bar magnet is defined by $\vec{\boldsymbol{\mu}} = q_m\vec{\ell}$, where $\vec{\boldsymbol{\mu}}$ is the magnetic moment of the magnet and $\vec{\ell}$ is the position of the north-pole end of the magnet relative to the south-pole end. Show that the torque exerted on a bar magnet in a uniform magnetic field $\vec{\boldsymbol{B}}$ is the same as if a force $+q_m\vec{\boldsymbol{B}}$ is exerted on the north-pole of the magnetic and a force $-q_m\vec{\boldsymbol{B}}$ is exerted on the south-pole.

Picture the Problem The configuration of the magnet and field are shown in the figure. We'll assume that a force $+q_{\text{m}}\vec{\boldsymbol{B}}$ is exerted on the north-pole end and a force $-q_{\text{m}}\vec{\boldsymbol{B}}$ is exerted on the south-pole end and show that this assumption leads to the familiar expression for the torque acting on a magnetic dipole.



Assuming that a force $+q_{\text{m}}\vec{\boldsymbol{B}}$ is exerted on the north-pole end and a force $-q_{\text{m}}\vec{\boldsymbol{B}}$ is exerted on the south-pole end, express the net torque acting on the bar magnet:

$$\tau = \frac{Bq_{\text{m}}\ell}{2}\sin\theta - \frac{-Bq_{\text{m}}\ell}{2}\sin\theta$$
$$= Bq_{\text{m}}\ell\sin\theta$$

Substitute for q_{m} to obtain:

$$\tau = B\frac{|\vec{\mu}|}{\ell}\ell\sin\theta = \mu B\sin\theta$$

or

$$\vec{\boldsymbol{\tau}} = \boxed{\vec{\boldsymbol{\mu}}\times\vec{\boldsymbol{B}}}$$

73 •• [SSM] A particle of mass m and charge q enters a region where there is a uniform magnetic field $\vec{\boldsymbol{B}}$ parallel with the x axis. The initial velocity of the particle is $\vec{\boldsymbol{v}} = v_{0x}\hat{\boldsymbol{i}} + v_{0y}\hat{\boldsymbol{j}}$, so the particle moves in a helix. (*a*) Show that the radius of the helix is $r = mv_{0y}/qB$. (*b*) Show that the particle takes a time $\Delta t = 2\pi m/qB$ to complete each turn of the helix. (*c*) What is the x component of the displacement of the particle during time given in Part (*b*)?

Picture the Problem We can use $\vec{\boldsymbol{F}} = q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$ to show that motion of the particle in the x direction is not affected by the magnetic field. The application of Newton's second law to motion of the particle in yz plane will lead us to the result that $r = mv_{0y}/qB$. By expressing the period of the motion in terms of v_{0y} we can show that the time for one complete orbit around the helix is $t = 2\pi m/qB$.

(*a*) Express the magnetic force acting on the particle:

$$\vec{\boldsymbol{F}} = q\vec{\boldsymbol{v}}\times\vec{\boldsymbol{B}}$$

Substitute for $\vec{v}$ and $\vec{B}$ and simplify to obtain:

$$\begin{aligned}\vec{F} &= q\left(v_{0x}\hat{i} + v_{0y}\hat{j}\right)\times B\hat{i}\\ &= qv_{0x}B\left(\hat{i}\times\hat{i}\right) + qv_{0y}B\left(\hat{j}\times\hat{i}\right)\\ &= 0 - qv_{0y}B\hat{k} = -qv_{0y}B\hat{k}\end{aligned}$$

that is, the motion in the direction of the magnetic field (the x direction) is not affected by the field.

Apply Newton's second law to the particle in the plane perpendicular to $\hat{i}$ (i.e., the yz plane):

$$qv_{0y}B = m\frac{v_{0y}^2}{r} \qquad (1)$$

Solving for r yields:

$$r = \boxed{\frac{mv_{0y}}{qB}}$$

(b) Relate the time for one orbit around the helix to the particle's orbital speed:

$$\Delta t = \frac{2\pi r}{v_{0y}}$$

Solve equation (1) for v_{0y}:

$$v_{0y} = \frac{qBr}{m}$$

Substitute for v_{0y} and simplify to obtain:

$$\Delta t = \frac{2\pi r}{\frac{qBr}{m}} = \boxed{\frac{2\pi m}{qB}}$$

(c) Because, as was shown in Part (a), the motion in the direction of the magnetic field (the x direction) is not affected by the field, the x component of the displacement of the particle as a function of t is:

$$x(t) = v_{\mathrm{ox}}t$$

For $t = \Delta t$:

$$x(\Delta t) = v_{\mathrm{ox}}\left(\frac{2\pi m}{qB}\right) = \boxed{\frac{2\pi mv_{\mathrm{ox}}}{qB}}$$

74 •• A metal crossbar of mass m rides on a parallel pair of long horizontal conducting rails separated by a distance L and connected to a device that supplies constant current I to the circuit, as shown in Figure 26-42. The circuit is in a region with a uniform magnetic field $\vec{B}$ whose direction is vertically downward.

There is no friction and the bar starts from rest at $t = 0$. (*a*) In which direction will the bar start to move? (*b*) Show that at time *t* the bar has a speed of $(BIL/m)t$.

Picture the Problem We can use a constant-acceleration equation to relate the velocity of the crossbar to its acceleration and Newton's second law to express the acceleration of the crossbar in terms of the magnetic force acting on it. We can determine the direction of motion of the crossbar using a right-hand rule or, equivalently, by applying $\vec{\boldsymbol{F}} = I\vec{\ell} \times \vec{\boldsymbol{B}}$.

(*a*) Because the magnetic force is to the right and the crossbar starts from rest, the motion of the crossbar will also be toward the right.

(*b*) Using a constant-acceleration equation, express the velocity of the bar as a function of its acceleration and the time it has been in motion:

$$v = v_0 + at$$

or, because $v_0 = 0$,

$$v = at$$

Use Newton's second law to express the acceleration of the rail:

$$a = \frac{F}{m}$$

where F is the magnitude of the magnetic force acting in the direction of the crossbar's motion.

Substitute for a to obtain:

$$v = \frac{F}{m}t$$

Express the magnetic force acting on the current-carrying crossbar:

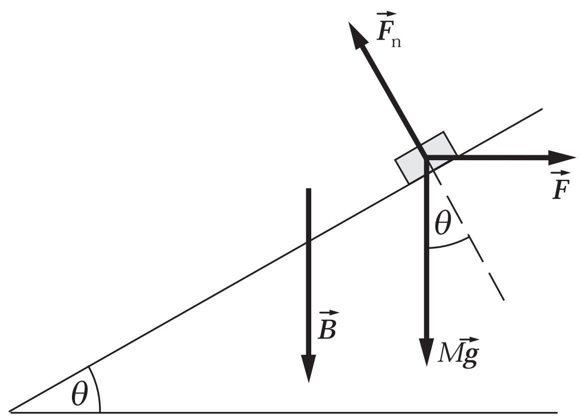
$$F = ILB$$

Substitute to obtain:

$$v = \boxed{\frac{ILB}{m}t}$$

75 •• **[SSM]** Assume that the rails Problem 74 are frictionless but tilted upward so that they make an angle θ with the horizontal, and with the current source attached to the low end of the rails. The magnetic field is still directed vertically downward. (*a*) What minimum value of B is needed to keep the bar from sliding down the rails? (*b*) What is the acceleration of the bar if B is twice the value found in Part (*a*)?

Picture the Problem Note that with the rails tilted, $\vec{F}$ still points horizontally to the right (I, and hence $\vec{\ell}$, is out of the page). Choose a coordinate system in which down the incline is the $+x$ direction. Then we can apply a condition for translational equilibrium to find the vertical magnetic field $\vec{B}$ needed to keep the bar from sliding down the rails. In Part (b) we can apply Newton's second law to find the acceleration of the crossbar when B is twice its value found in (a).



(a) Apply $\sum F_x = 0$ to the crossbar to obtain:

$$mg\sin\theta - I\ell B\cos\theta = 0$$

Solving for B yields:

$$B = \frac{mg}{I\ell}\tan\theta \text{ and } \vec{B} = \boxed{-\frac{mg}{I\ell}\tan\theta\,\hat{\boldsymbol{u}}_\text{v}}$$

where $\hat{\boldsymbol{u}}_\text{v}$ is a unit vector in the vertical direction.

(b) Apply Newton's second law to the crossbar to obtain:

$$I\ell B'\cos\theta - mg\sin\theta = ma$$

Solving for a yields:

$$a = \frac{I\ell B'}{m}\cos\theta - g\sin\theta$$

Substitute $B' = 2B$ and simplify to obtain:

$$a = \frac{2I\ell\frac{mg}{I\ell}\tan\theta}{m}\cos\theta - g\sin\theta$$

$$= 2g\sin\theta - g\sin\theta = \boxed{g\sin\theta}$$

Note that the direction of the acceleration is up the incline.

76 •• A long, narrow bar magnet that has magnetic moment $\vec{\boldsymbol{\mu}}$ parallel to its long axis is suspended at its center as a frictionless compass needle. When placed in region with a horizontal magnetic field $\vec{\boldsymbol{B}}$, the needle lines up with the field. If it is displaced by a small angle θ, show that the needle will oscillate about its equilibrium position with frequency $f=\dfrac{1}{2\pi}\sqrt{\dfrac{\mu B}{I}}$, where I is the moment of inertia of the needle about the point of suspension.

Picture the Problem We're being asked to show that, for small displacements from equilibrium, the bar magnet executes simple harmonic motion. To show its motion is SHM we need to show that the bar magnet experiences a linear restoring torque when displaced from equilibrium. We can accomplish this by applying Newton's second law in rotational form and using a small angle approximation to obtain the differential equation for simple harmonic motion. Once we have the differential equation of motion we can identify ω and express f.

Apply Newton's second law to the bar magnet:

$$-\mu B\sin\theta = I\frac{d^2\theta}{dt^2}$$

where the minus sign indicates that the torque acts in such a manner as to align the magnet with the magnetic field and I is the moment of inertia of the magnet.

For small displacements from equilibrium, $\theta << 1$ and:

$$\sin\theta\approx\theta$$

Hence our differential equation of motion becomes:

$$I\frac{d^2\theta}{dt^2}=-\mu B\theta$$

Thus for small displacements from equilibrium we see that the differential equation describing the motion of the bar magnet is the differential equation of simple harmonic motion. Solve this equation for $d^2\theta/dt^2$ to obtain:

$$\frac{d^2\theta}{dt^2}=-\frac{\mu B}{I}\theta=-\omega^2\theta$$

where $\omega=\sqrt{\dfrac{\mu B}{I}}$

Relate f to ω to obtain:

$$f=\frac{\omega}{2\pi}=\boxed{\frac{1}{2\pi}\sqrt{\frac{\mu B}{I}}}$$

77 •• A straight conducting wire whose length is 20 m is parallel to the *y* axis and is moving in the +*x* direction with a speed of 20 m/s in a region with a magnetic field given by $0.50\,\text{T}\,\hat{\boldsymbol{k}}$. (*a*) Because of the magnetic force, electrons move to one end of the wire leaving the other end positively charged, until the electric field due to this charge separation exerts a force on the conduction electrons that balances the magnetic force. Find the magnitude and direction of this electric field in the steady state situation. (*b*) Which end of the wire is positively charged and which end is negatively charged? (*c*) Suppose the moving wire is 2.0-m long. What is the potential difference between its two ends due to this electric field?

Picture the Problem (*a*) We can use a condition for translational equilibrium to relate $\vec{E}$ to $\vec{F}$. In Part (*c*) we can apply the definition of electric field in terms of potential difference to evaluate the difference in potential between the ends of the moving wire.

(*a*) Sum the forces acting on an electron under steady-state conditions to obtain:

$$q\vec{E} + \vec{F} = 0 \Rightarrow \vec{E} = -\frac{\vec{F}}{q}$$

The magnetic force on an electron in the conductor is given by:

$$\vec{F} = q\vec{v} \times \vec{B} = qv\hat{\boldsymbol{i}} \times B\hat{\boldsymbol{k}} = qvB\left(\hat{\boldsymbol{i}} \times \hat{\boldsymbol{k}}\right) = -qvB\hat{\boldsymbol{j}}$$

Substituting for $\vec{F}$ and simplifying yields:

$$\vec{E} = -\frac{-qvB\hat{\boldsymbol{j}}}{q} = vB\hat{\boldsymbol{j}}$$

Substitute numerical values and evaluate $\vec{E}$:

$$\vec{E} = (20\,\text{m/s})(0.50\,\text{T})\hat{\boldsymbol{j}} = \boxed{(10\,\text{V/m})\hat{\boldsymbol{j}}}$$

(*b*) Because the magnetic force acting on the conduction electrons is in the +*y* direction, the end of the wire that is in the +*y* direction becomes negatively charged and the end of the wire that is in the −*y* direction becomes positively charged. The positive end has the lesser *y* coordinate.

(*c*) The potential difference between the ends of the wire is:

$$\Delta V = E\Delta y = (10.0\,\text{V/m})(2.0\,\text{m}) = \boxed{20\,\text{V}}$$

78 ••• A circular loop of wire that has a mass *m* and carries a constant current *I* is in a region with a uniform magnetic field. It is initially in equilibrium and its magnetic moment is aligned with the magnetic field. The loop is given a small angular displacement about an axis through it center and perpendicular to the magnetic field and then released. What is the period of the subsequent motion?

(Assume that the only torque exerted on the loop is due to the magnetic field and that there are no other forces acting on the loop.)

Picture the Problem We're being asked to show that, for small displacements from equilibrium, the circular loop executes simple harmonic motion. To show its motion is SHM we must show that the loop experiences a linear restoring torque when displaced from equilibrium. We can accomplish this by applying Newton's second law in rotational form and using a small angle approximation to obtain the differential equation for simple harmonic motion. Once we have the differential equation we can identify ω and express the period T of the motion.

Apply Newton's second law to the loop:

$$-IAB\sin\theta = I_{\text{inertia}}\frac{d^2\theta}{dt^2}$$

where the minus sign indicates that the torque acts in such a manner as to align the loop with the magnetic field and I_{inertia} is the moment of inertia of the loop.

For small displacements from equilibrium, $\theta << 1$ and:

$$\sin\theta \approx \theta$$

Hence, our differential equation of motion becomes:

$$I_{\text{inertia}}\frac{d^2\theta}{dt^2} = -IAB\theta$$

Thus for small displacements from equilibrium we see that the differential equation describing the motion of the current loop is the differential equation of simple harmonic motion. Solve this equation for $d^2\theta/dt^2$ to obtain:

$$\frac{d^2\theta}{dt^2} = -\frac{IAB}{I_{\text{inertia}}}\theta$$

.

Noting that the moment of inertia of a hoop about its diameter is $\frac{1}{2}mR^2$, substitute for I_{inertia} and simplify to obtain:

$$\frac{d^2\theta}{dt^2} = -\frac{I\pi R^2 B}{\frac{1}{2}mR^2}\theta = -\frac{2I\pi B}{m}\theta = -\omega^2\theta$$

where $\omega = \sqrt{\frac{2\pi IB}{m}}$

The period T of the motion is related to the angular frequency ω:

$$T = \frac{2\pi}{\omega}$$

Substituting for ω and simplifying yields:

$$T = \boxed{\sqrt{\frac{2\pi m}{IB}}}$$

79 ••• A small bar magnet has a magnetic moment $\vec{\boldsymbol{\mu}}$ that makes an angle θ with the x axis. The magnet is in a region that has a *non-uniform* magnetic field given by $\vec{\boldsymbol{B}} = B_x(x)\hat{\boldsymbol{i}} + B_y(y)\hat{\boldsymbol{j}}$. Using $F_x = -\partial U/\partial x$, $F_y = -\partial U/\partial y$ and $F_z = -\partial U/\partial z$, show that there is a net magnetic force on the magnet that is given by $\vec{\boldsymbol{F}} = \mu_x \frac{\partial B_x}{\partial x}\hat{\boldsymbol{i}} + \mu_y \frac{\partial B_y}{\partial y}\hat{\boldsymbol{j}}$.

Picture the Problem We can express $\vec{\boldsymbol{\mu}}$ in terms of its components and calculate U from $\vec{\boldsymbol{\mu}}$ and $\vec{\boldsymbol{B}}$ using $U = -\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}}$. Knowing U we can calculate the components of $\vec{\boldsymbol{F}}$ using $F_x = -dU/dx$ and $F_y = -dU/dy$.

Express the net force acting on the magnet in terms of its components:

$$\vec{\boldsymbol{F}} = F_x\hat{\boldsymbol{i}} + F_y\hat{\boldsymbol{j}} \qquad (1)$$

Express $\vec{\boldsymbol{\mu}}$ in terms of its components:

$$\vec{\boldsymbol{\mu}} = \mu_x\hat{\boldsymbol{i}} + \mu_y\hat{\boldsymbol{j}} + \mu_z\hat{\boldsymbol{k}}$$

Express the potential energy of the bar magnetic in the nonuniform magnetic field:

$$\begin{aligned} U &= -\vec{\boldsymbol{\mu}}\cdot\vec{\boldsymbol{B}} \\ &= -\left(\mu_x\hat{\boldsymbol{i}} + \mu_y\hat{\boldsymbol{j}} + \mu_z\hat{\boldsymbol{k}}\right)\cdot\left(B_x(x)\hat{\boldsymbol{i}} + B_y(y)\hat{\boldsymbol{j}}\right) \\ &= -\mu_x B_x(x) - \mu_y B_y(y) \end{aligned}$$

Because $\vec{\boldsymbol{\mu}}$ is constant but $\vec{\boldsymbol{B}}$ depends on x and y:

$$F_x = -\frac{dU}{dx} = \mu_x\left(\frac{\partial B_x}{\partial x}\right)$$

and

$$F_y = -\frac{dU}{dy} = \mu_y\left(\frac{\partial B_y}{\partial y}\right)$$

Substitute in equation (1) to obtain:

$$\vec{\boldsymbol{F}} = \boxed{\mu_x \frac{\partial B_x}{\partial x}\hat{\boldsymbol{i}} + \mu_y \frac{\partial B_y}{\partial y}\hat{\boldsymbol{j}}}$$

80 •• A proton, a deuteron and an alpha particle all have the same kinetic energy. They are moving in a region with a uniform magnetic field that is perpendicular to each of their velocities. Let R_p, R_d, and R_α be the radii of their circular orbits, respectively. The deuteron has a charge that is equal to the charge a proton has, and an alpha particle has a charge that is equal to twice the charge a proton has. Find the ratios R_d/R_p and R_α/R_p. Assume that $m_\alpha = 2m_\text{d} = 4m_\text{p}$.

Picture the Problem We can apply Newton's second law to an orbiting particle to obtain an expression for the radius of its orbit R as a function of its mass m, charge q, speed v, and the magnitude of the magnetic field B.

Apply Newton's second law to an orbiting particle to obtain:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB}$$

Express the kinetic energy of the particle:

$$K = \tfrac{1}{2}mv^2 \Rightarrow v = \sqrt{\frac{2K}{m}}$$

Substitute for v in the expression for r and simplify to obtain:

$$r = \frac{m}{qB}\sqrt{\frac{2K}{m}} = \frac{1}{qB}\sqrt{2Km} \qquad (1)$$

Using equation (1), express the ratio $R_\mathrm{d}/R_\mathrm{p}$:

$$\frac{R_\mathrm{d}}{R_\mathrm{p}} = \frac{\frac{1}{q_\mathrm{d}B}\sqrt{2Km_\mathrm{d}}}{\frac{1}{q_\mathrm{p}B}\sqrt{2Km_\mathrm{p}}} = \frac{q_\mathrm{p}}{q_\mathrm{d}}\sqrt{\frac{m_\mathrm{d}}{m_\mathrm{p}}} = \frac{e}{e}\sqrt{\frac{2m_\mathrm{p}}{m_\mathrm{p}}} = \boxed{\sqrt{2}}$$

Using equation (1), express the ratio R_α/R_p:

$$\frac{R_\alpha}{R_\mathrm{p}} = \frac{\frac{1}{q_\alpha B}\sqrt{2Km_\alpha}}{\frac{1}{q_\mathrm{p}B}\sqrt{2Km_\mathrm{p}}} = \frac{q_\mathrm{p}}{q_\alpha}\sqrt{\frac{m_\alpha}{m_\mathrm{p}}} = \frac{e}{2e}\sqrt{\frac{4m_\mathrm{p}}{m_\mathrm{p}}} = \boxed{1}$$

81 ••• Your forensic chemistry group, working closely with the local law enforcement agencies, has acquired a mass spectrometer similar to that discussed in the text. It employs a uniform magnetic field that has a magnitude of 0.75 T. To calibrate the mass spectrometer, you decide to measure the masses of various carbon isotopes by measuring the position of impact of the various singly ionized carbon ions that have entered the spectrometer with a kinetic energy of 25 keV. A wire chamber with position sensitivity of 0.50 mm is part of the apparatus. What will be the limit on its mass resolution (in kg) for ions in this mass range, that is those whose mass is on the order of that of a carbon atom?

Picture the Problem We can apply Newton's second law, with the force on a moving charged particle in a magnetic field as the net force, to an ion in the spectrometer to obtain an expression for the radius of its trajectory as a function of its momentum. We can then use the definition of kinetic energy to eliminate

the speed of the ion from the expression for the radius of its trajectory. Differentiating the expression for the range (twice the radius of curvature) of the ions with respect to their mass will yield the mass resolution for ions whose masses are roughly 19.9×10^{-27} kg. We'll assume that the carbon atoms are singly ionized.

Apply Newton's second law to an ion in the spectrometer to obtain:

$$qvB = m\frac{v^2}{r} \Rightarrow r = \frac{mv}{qB} \qquad (1)$$

where q is the charge of the ion, m is its mass, and r is the radius of curvature of its path.

From the definition of kinetic energy we have:

$$E = \tfrac{1}{2}mv^2 \Rightarrow v = \sqrt{\frac{2E}{m}}$$

Substituting for v in equation (1) and simplifying yields:

$$r = \frac{m\sqrt{\frac{2E}{m}}}{qB} = \frac{\sqrt{2mE}}{qB} \qquad (2)$$

The range R of the ions is twice their radius of curvature:

$$R = \frac{2\sqrt{2mE}}{qB} = \frac{\sqrt{8mE}}{qB} \qquad (3)$$

Differentiate R with respect to m to obtain:

$$\frac{dR}{dm} = \frac{d}{dm}\left(\frac{\sqrt{8mE}}{qB}\right) = \frac{\sqrt{8E}}{qB}\frac{d}{dm}\left(\sqrt{m}\right)$$

$$= \frac{\sqrt{8E}}{qB}\frac{1}{2\sqrt{m}} = \frac{\sqrt{\frac{2E}{m}}}{qB} = \sqrt{\frac{2E}{mq^2B^2}}$$

Solving for dm yields:

$$dm = \frac{dR}{\sqrt{\frac{2E}{mq^2B^2}}} = dR\sqrt{\frac{mq^2B^2}{2E}}$$

Substitute numerical values and evaluate dm:

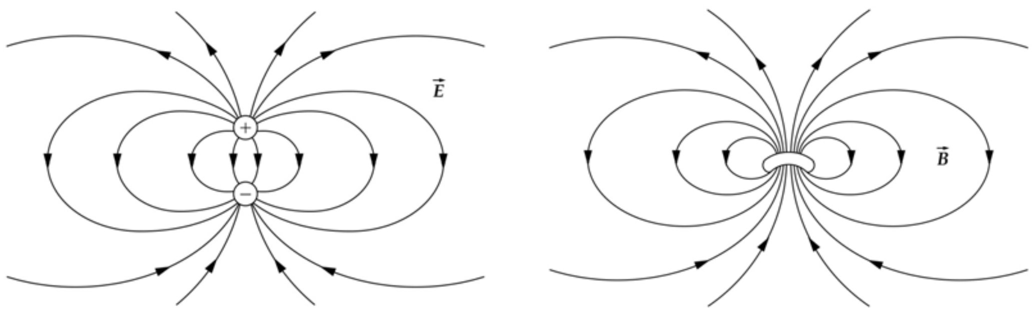
$$dm = (0.50\,\text{mm})\sqrt{\frac{\left(19.9\times10^{-27}\,\text{kg}\right)\left(1.602\times10^{-19}\,\text{C}\right)^2\left(0.80\,\text{T}\right)^2}{2\left(25\,\text{keV}\times\frac{1.602\times10^{-19}\,\text{C}}{\text{eV}}\right)}} = \boxed{1.0\times10^{-28}\,\text{kg}}$$

Chapter 27
Sources of the Magnetic Field

Conceptual Problems

1 • Sketch the field lines for the electric dipole and the magnetic dipole shown in Figure 27-47. How do the field lines differ in appearance close to the center of each dipole?

Picture the Problem Note that, while the two far fields (the fields far from the dipoles) are the same, the two near fields (the fields near the dipoles) are not. At the center of the electric dipole, the electric field is antiparallel to the direction of the far field above and below the dipole, and at the center of the magnetic dipole, the magnetic field is parallel to the direction of the far field above and below the dipole. It is especially important to note that while the electric field lines begin and terminate on electric charges, the magnetic field lines are continuous, that is, they form closed loops.



2 • Two wires lie in the plane of the page and carry equal currents in opposite directions, as shown in Figure 27- 48. At a point midway between the wires, the magnetic field is (*a*) zero, (*b*) into the page, (*c*) out of the page, (*d*) toward the top or bottom of the page, (*e*) toward one of the two wires.

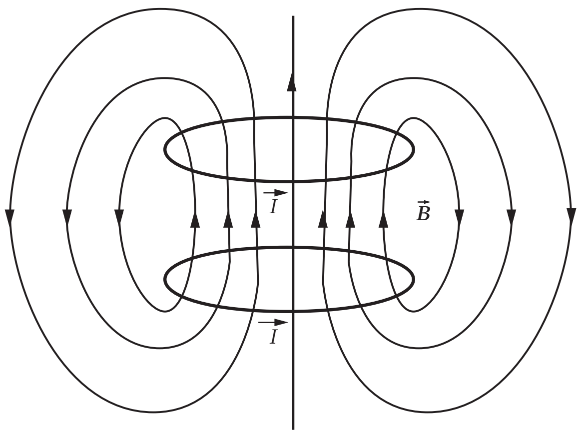
Determine the Concept Applying the right-hand rule to the wire to the left we see that the magnetic field due to its current is out of the page at the midpoint. Applying the right-hand rule to the wire to the right we see that the magnetic field due to its current is also out of the page at the midpoint. Hence, the sum of the magnetic fields is out of the page as well. 1is correct.

3 • Parallel wires 1 and 2 carry currents I_1 and I_2, respectively, where $I_2 = 2I_1$. The two currents are in the same direction. The magnitudes of the magnetic force by current 1 on wire 2 and by current 2 on wire 1 are F_{12} and F_{21}, respectively. These magnitudes are related by (*a*) $F_{21} = F_{12}$, (*b*) $F_{21} = 2F_{12}$, (*c*) $2F_{21} = F_{12}$, (*d*) $F_{21} = 4F_{12}$, (*e*) $4F_{21} = F_{12}$.

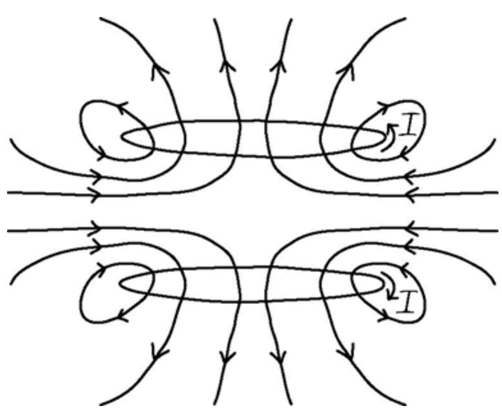
Determine the Concept While we could express the force wire 1 exerts on wire 2 and compare it to the force wire 2 exerts on wire 1 to show that they are the same, it is simpler to recognize that these are action and reaction forces. $\boxed{(a)}$ is correct.

4 • Make a field-line sketch of the magnetic field due to the currents in the pair of identical coaxial coils shown in Figure 27-49. Consider two cases: (*a*) the currents in the coils have the same magnitude and have the same direction and (*b*) the currents in the coils have the same magnitude and have the opposite directions.

Picture the Problem (*a*) The field-line sketch follows. An assumed direction for the current in the coils is shown in the diagram. Note that the field is stronger in the region between the coaxial coils and that the field lines have neither beginning nor ending points as do electric-field lines. Because there are an uncountable infinity of lines, only a representative few have been shown.



(*b*) The field-line sketch is shown below. An assumed direction for the current in the coils is shown in the diagram. Note that the field lines never begin or end and that they do not touch or cross each other. Because there are an uncountable infinity of lines, only a representative few have been shown.



5 • [SSM] Discuss the differences and similarities between Gauss's law for magnetism and Gauss's law for electricity.

Determine the Concept Both tell you about the respective fluxes through closed surfaces. In the electrical case, the flux is proportional to the net charge enclosed. In the magnetic case, the flux is always zero because there is no such thing as magnetic charge (a magnetic monopole). The source of the magnetic field is NOT the equivalent of electric charge; that is, it is NOT a thing called magnetic charge, but rather it is moving electric charges.

6 • Explain how you would modify Gauss's law if scientists discovered that single, isolated magnetic poles actually existed.

Determine the Concept Gauss' law for magnetism now reads: ″The flux of the magnetic field through any closed surface is equal to zero.″ Just like each electric pole has an electric pole strength (an amount of electric charge), each magnetic pole would have a magnetic pole strength (an amount of magnetic charge). Gauss' law for magnetism would read: ″The flux of the magnetic field through any closed surface is proportional to the total amount of magnetic charge inside.″

7 • [SSM] You are facing directly into one end of a long solenoid and the magnetic field inside of the solenoid points away from you. From your perspective, is the direction of the current in the solenoid coils clockwise or counterclockwise? Explain your answer.

Determine the Concept Application of the right-hand rule leads one to conclude that the current is clockwise.

8 • Opposite ends of a helical metal spring are connected to the terminals of a battery. Do the spacings between the coils of the spring tend to increase, decrease, or remain the same when the battery is connected? Explain your answer.

Determine the Concept Decrease. The coils attract each other and tend to move closer together when there is current in the spring.

9 • The current density is constant and uniform in a long straight wire that has a circular cross section. True or false:

(*a*) The magnitude of the magnetic field produced by this wire is greatest at the surface of the wire.
(*b*) The magnetic field strength in the region surrounding the wire varies inversely with the square of the distance from the wire's central axis.
(*c*) The magnetic field is zero at all points on the wire's central axis.
(*d*) The magnitude of the magnetic field inside the wire increases linearly with the distance from the wire's central axis.

(*a*) True. The magnetic field due to an infinitely long, straight wire is given by $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$, where R is the perpendicular distance to the field point. Because the magnetic field decreases linearly as the distance from the wire's central axis, the maximum field produced by this current is at the surface of the wire.

(*b*) False. Because the magnetic field due to an infinitely long, straight wire is given by $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$, where R is the perpendicular distance to the field point, the magnetic field outside the wire is inversely proportional to the distance from the wire's central axis.

(*c*) True. Because $I_C = 0$ at the center of the wire, Ampere's law ($\oint_C \vec{\boldsymbol{B}} \cdot d\vec{\ell} = \mu_0 I_C$) tells us that the magnetic field is zero at the center of the wire.

(*d*) True. Application of Ampere's law shows that, inside the wire, $B = \frac{\mu_0}{2\pi}\frac{I}{R^2}r$, where R is the radius of the wire and r is the distance from the center of the wire.

10 • If the magnetic susceptibility of a material is positive,

(*a*) paramagnetic effects or ferromagnetic effects must be greater than diamagnetic effects,
(*b*) diamagnetic effects must be greater than paramagnetic effects,
(*c*) diamagnetic effects must be greater than ferromagnetic effects,
(*d*) ferromagnetic effects must be greater than paramagnetic effects,
(*e*) paramagnetic effects must be greater than ferromagnetic effects.

Determine the Concept The magnetic susceptibility χ_m is defined by the equation $\vec{\boldsymbol{M}} = \chi_m \frac{\vec{\boldsymbol{B}}_{app}}{\mu_0}$, where $\vec{\boldsymbol{M}}$ is the magnetization vector and $\vec{\boldsymbol{B}}_{app}$ is the applied magnetic field. For paramagnetic materials, χ_m is a small positive number that depends on temperature, whereas for diamagnetic materials, it is a small negative constant independent of temperature. $\boxed{(a)}$ is correct.

11 • **[SSM]** Of the four gases listed in Table 27-1, which are diamagnetic and which are paramagnetic?

Determine the Concept H_2, CO_2, and N_2 are diamagnetic ($\chi_m < 0$); O_2 is paramagnetic ($\chi_m > 0$).

12 • When a current is passed through the wire in Figure 27- 50, will the wire tend to bunch up or will it tend to form a circle? Explain your answer.

Determine the Concept It will tend to form a circle. Oppositely directed current elements will repel each other, and so opposite sides of the loop will repel.

The Magnetic Field of Moving Point Charges

13 • **[SSM]** At time t = 0, a particle has a charge of 12 μC, is located in the z = 0 plane at x = 0, y = 2.0 m, and has a velocity equal to $30\ \text{m/s}\ \hat{\boldsymbol{i}}$. Find the magnetic field in the z = 0 plane at (a) the origin, (b) x = 0, y = 1.0 m, (c) x = 0, y = 3.0 m, and (d) x = 0, y = 4.0 m.

Picture the Problem We can substitute for $\vec{v}$ and q in the equation describing the magnetic field of the moving charged particle ($\vec{B} = \dfrac{\mu_0}{4\pi}\dfrac{q\vec{v}\times\hat{r}}{r^2}$), evaluate r and $\hat{r}$ for each of the given points of interest, and then find $\vec{B}$.

The magnetic field of the moving charged particle is given by:

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2}$$

Substitute numerical values and simplify to obtain:

$$\vec{B} = \left(10^{-7}\ \text{N/A}^2\right)(12\ \mu\text{C})\frac{(30\ \text{m/s})\hat{i}\times\hat{r}}{r^2} = \left(36.0\ \text{pT}\cdot\text{m}^2\right)\frac{\hat{i}\times\hat{r}}{r^2}$$

(a) Find r and $\hat{r}$ for the particle at (0, 2.0 m) and the point of interest at the origin:

$\vec{r} = -(2.0\ \text{m})\hat{j}$, $r = 2.0\ \text{m}$, and $\hat{r} = -\hat{j}$

Evaluating $\vec{B}(0,0)$ yields:

$$\vec{B}(0,0) = \left(36.0\ \text{pT}\cdot\text{m}^2\right)\frac{\hat{i}\times\left(-\hat{j}\right)}{(2.0\ \text{m})^2} = \boxed{-(9.0\ \text{pT})\hat{k}}$$

(b) Find r and $\hat{r}$ for the particle at (0, 2.0 m) and the point of interest at (0, 1.0 m):

$\vec{r} = -(1.0\ \text{m})\hat{j}$, $r = 1.0\ \text{m}$, and $\hat{r} = -\hat{j}$

Evaluate $\vec{B}(0,1.0\,\text{m})$ to obtain:

$$\vec{B}(0,1.0\,\text{m}) = (36.0\,\text{pT}\cdot\text{m}^2)\frac{\hat{i}\times(-\hat{j})}{(1.0\,\text{m})^2} = \boxed{-(36\,\text{pT})\hat{k}}$$

(*c*) Find *r* and $\hat{r}$ for the particle at (0, 2.0 m) and the point of interest at (0, 3.0 m):

$\vec{r} = (1.0\,\text{m})\hat{j}$, $r = 1.0\,\text{m}$, and $\hat{r} = \hat{j}$

Evaluating $\vec{B}(0,3.0\,\text{m})$ yields:

$$\vec{B}(0,3.0\,\text{m}) = (36.0\,\text{pT}\cdot\text{m}^2)\frac{\hat{i}\times\hat{j}}{(1.0\,\text{m})^2} = \boxed{(36\,\text{pT})\hat{k}}$$

(*d*) Find *r* and $\hat{r}$ for the particle at (0, 2.0 m) and the point of interest at (0, 4.0 m):

$\vec{r} = (2.0\,\text{m})\hat{j}$, $r = 2.0\,\text{m}$, and $\hat{r} = \hat{j}$

Evaluate $\vec{B}(0,4.0\,\text{m})$ to obtain:

$$\vec{B}(0,4.0\,\text{m}) = (36.0\,\text{pT}\cdot\text{m}^2)\frac{\hat{i}\times\hat{j}}{(2.0\,\text{m})^2} = \boxed{(9.0\,\text{pT})\hat{k}}$$

14 • At time $t = 0$, a particle has a charge of 12 μC, is located in the $z = 0$ plane at $x = 0$, $y = 2.0$ m, and has a velocity equal to $30\ \text{m/s}\,\hat{i}$. Find the magnetic field in the $z = 0$ plane at (*a*) $x = 1.0$ m, $y = 3.0$ m, (*b*) $x = 2.0$ m, $y = 2.0$ m, and (*c*) $x = 2.0$ m, $y = 3.0$ m.

Picture the Problem We can substitute for $\vec{v}$ and *q* in the equation describing the magnetic field of the moving charged particle ($\vec{B} = \frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2}$), evaluate *r* and $\hat{r}$ for each of the given points of interest, and substitute to find $\vec{B}$.

The magnetic field of the moving charged particle is given by:

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2}$$

Substitute numerical values and simplify to obtain:

$$\vec{B} = (10^{-7}\ \text{N/A}^2)(12\,\mu\text{C})\frac{(30\,\text{m/s})\hat{i}\times\hat{r}}{r^2} = (36.0\,\text{pT}\cdot\text{m}^2)\frac{\hat{i}\times\hat{r}}{r^2}$$

(*a*) Find r and $\hat{\boldsymbol{r}}$ for the particle at (0, 2.0 m) and the point of interest at (1.0 m, 3.0 m):

$\vec{r} = (1.0\,\mathrm{m})\hat{\boldsymbol{i}} + (1.0\,\mathrm{m})\hat{\boldsymbol{j}}$, $r = \sqrt{2}\,\mathrm{m}$, and $\hat{\boldsymbol{r}} = \frac{1}{\sqrt{2}}\hat{\boldsymbol{i}} + \frac{1}{\sqrt{2}}\hat{\boldsymbol{j}}$

Substitute for $\hat{\boldsymbol{r}}$ and r in $\vec{\boldsymbol{B}} = (36.0\,\mathrm{pT\cdot m^2})\frac{\hat{\boldsymbol{i}}\times\hat{\boldsymbol{r}}}{r^2}$ and evaluate $\vec{\boldsymbol{B}}(1.0\,\mathrm{m},3.0\,\mathrm{m})$:

$$\vec{\boldsymbol{B}}(1.0\,\mathrm{m},3.0\,\mathrm{m}) = (36.0\,\mathrm{pT\cdot m^2})\frac{\hat{\boldsymbol{i}}\times\left(\frac{1}{\sqrt{2}}\hat{\boldsymbol{i}} + \frac{1}{\sqrt{2}}\hat{\boldsymbol{j}}\right)}{\left(\sqrt{2}\,\mathrm{m}\right)^2} = \frac{(36.0\,\mathrm{pT\cdot m^2})}{\sqrt{2}}\frac{\hat{\boldsymbol{k}}}{\left(\sqrt{2}\,\mathrm{m}\right)^2}$$

$$= \boxed{(13\,\mathrm{pT})\hat{\boldsymbol{k}}}$$

(*b*) Find r and $\hat{\boldsymbol{r}}$ for the particle at (0, 2.0 m) and the point of interest at (2.0 m, 2.0 m):

$\vec{r} = (2.0\,\mathrm{m})\hat{\boldsymbol{i}}$, $r = 2.0\,\mathrm{m}$, and $\hat{\boldsymbol{r}} = \hat{\boldsymbol{i}}$

Substitute for $\hat{\boldsymbol{r}}$ and r in $\vec{\boldsymbol{B}} = (36.0\,\mathrm{pT\cdot m^2})\frac{\hat{\boldsymbol{i}}\times\hat{\boldsymbol{r}}}{r^2}$ and evaluate $\vec{\boldsymbol{B}}(2.0\,\mathrm{m},2.0\,\mathrm{m})$:

$$\vec{\boldsymbol{B}}(2.0\,\mathrm{m},2.0\,\mathrm{m}) = (36.0\,\mathrm{pT\cdot m^2})\frac{\hat{\boldsymbol{i}}\times\hat{\boldsymbol{i}}}{(2.0\,\mathrm{m})^2} = \boxed{0}$$

(*c*) Find r and $\hat{\boldsymbol{r}}$ for the particle at (0, 2.0 m) and the point of interest at (2.0 m, 3.0 m):

$\vec{r} = (2.0\,\mathrm{m})\hat{\boldsymbol{i}} + (1.0\,\mathrm{m})\hat{\boldsymbol{j}}$, $r = \sqrt{5}\,\mathrm{m}$, and $\hat{\boldsymbol{r}} = \frac{2}{\sqrt{5}}\hat{\boldsymbol{i}} + \frac{1}{\sqrt{5}}\hat{\boldsymbol{j}}$

Substitute for $\hat{\boldsymbol{r}}$ and r in $\vec{\boldsymbol{B}} = (36.0\,\mathrm{pT\cdot m^2})\frac{\hat{\boldsymbol{i}}\times\hat{\boldsymbol{r}}}{r^2}$ and evaluate $\vec{\boldsymbol{B}}(2.0\,\mathrm{m},3.0\,\mathrm{m})$:

$$\vec{\boldsymbol{B}}(2.0\,\mathrm{m},3.0\,\mathrm{m}) = (36.0\,\mathrm{pT\cdot m^2})\frac{\hat{\boldsymbol{i}}\times\left(\frac{2}{\sqrt{5}}\hat{\boldsymbol{i}} + \frac{1}{\sqrt{5}}\hat{\boldsymbol{j}}\right)}{\left(\sqrt{5}\,\mathrm{m}\right)^2} = \boxed{(3.2\,\mathrm{pT})\hat{\boldsymbol{k}}}$$

15 • A proton has a velocity of 1.0×10^2 m/s $\hat{\boldsymbol{i}} + 2.0\times10^2$ m/s $\hat{\boldsymbol{j}}$ and is located in the z = 0 plane at x = 3.0 m, y = 4.0 m at some time t. Find the magnetic field in the z = 0 plane at (*a*) x = 2.0 m, y = 2.0 m, (*b*) x = 6.0 m, y = 4.0 m, and (*c*) x = 3.0 m, y = 6.0 m.

Picture the Problem We can substitute for $\vec{v}$ and q in the equation describing the magnetic field of the moving proton ($\vec{B}=\frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2}$), evaluate r and $\hat{r}$ for each of the given points of interest, and substitute to find $\vec{B}$.

The magnetic field of the moving proton is given by:

$$\vec{B}=\frac{\mu_0}{4\pi}\frac{q\vec{v}\times\hat{r}}{r^2}$$

Substituting numerical values yields:

$$\begin{aligned}\vec{B}&=\left(10^{-7}\ \text{N/A}^2\right)\left(1.602\times10^{-19}\,\text{C}\right)\frac{\left[\left(1.0\times10^2\ \text{m/s}\right)\hat{i}+\left(2.0\times10^2\ \text{m/s}\right)\hat{j}\right]\times\hat{r}}{r^2}\\&=\left(1.60\times10^{-24}\ \text{T}\cdot\text{m}^2\right)\frac{\left(1.0\,\hat{i}+2.0\hat{j}\right)\times\hat{r}}{r^2}\end{aligned}$$

(*a*) Find r and $\hat{r}$ for the proton at (3.0 m, 4.0 m) and the point of interest at (2.0 m, 2.0 m):

$\vec{r}=-(1.0\,\text{m})\hat{i}-(2.0\,\text{m})\hat{j}$, $r=\sqrt{5}\,\text{m}$, and $\hat{r}=-\frac{1}{\sqrt{5}}\hat{i}-\frac{2}{\sqrt{5}}\hat{j}$

Substitute for $\hat{r}$ and r in $\vec{B}=\left(1.60\times10^{-24}\ \text{T}\cdot\text{m}^2\right)\frac{\left(1.0\,\hat{i}+2.0\hat{j}\right)\times\hat{r}}{r^2}$ and evaluate $\vec{B}(2.0\,\text{m},2.0\,\text{m})$:

$$\begin{aligned}\vec{B}(2.0\,\text{m},2.0\,\text{m})&=\left(1.60\times10^{-24}\ \text{T}\cdot\text{m}^2\right)\frac{\left(1.0\hat{i}+2.0\hat{j}\right)\times\left(-\frac{1}{\sqrt{5}}\hat{i}-\frac{2}{\sqrt{5}}\hat{j}\right)}{r^2}\\&=\frac{\left(1.60\times10^{-24}\ \text{T}\cdot\text{m}^2\right)}{\sqrt{5}}\left[\frac{-2.0\hat{k}+2.0\hat{k}}{\left(\sqrt{5}\,\text{m}\right)^2}\right]=\boxed{0}\end{aligned}$$

(*b*) Find r and $\hat{r}$ for the proton at (3.0 m, 4.0 m) and the point of interest at (6.0 m, 4.0 m):

$\vec{r}=(3.0\,\text{m})\hat{i}$, $r=3.0\,\text{m}$, and $\hat{r}=\hat{i}$

Substitute for $\hat{r}$ and r in $\vec{B}=\left(1.60\times10^{-24}\ \text{T}\cdot\text{m}^2\right)\frac{\left(1.0\,\hat{i}+2.0\hat{j}\right)\times\hat{r}}{r^2}$ and evaluate $\vec{B}(6.0\,\text{m},4.0\,\text{m})$:

$$\vec{B}(6.0\,\text{m},4.0\,\text{m}) = \left(1.60\times10^{-24}\,\text{T}\cdot\text{m}^2\right)\frac{\left(1.0\,\hat{i}+2.0\,\hat{j}\right)\times\hat{i}}{(3.0\,\text{m})^2}$$

$$= \left(1.60\times10^{-24}\,\text{T}\cdot\text{m}^2\right)\left(\frac{-2.0\,\hat{k}}{9.0\,\text{m}^2}\right) = \boxed{-\left(3.6\times10^{-25}\,\text{T}\right)\hat{k}}$$

(*c*) Find *r* and $\hat{r}$ for the proton at (3.0 m, 4.0 m) and the point of interest at the (3.0 m, 6.0 m):

$\vec{r} = (2.0\,\text{m})\hat{j}$, $r = 2.0\,\text{m}$, and $\hat{r} = \hat{j}$

Substitute for $\hat{r}$ and *r* in $\vec{B} = \left(1.60\times10^{-24}\,\text{T}\cdot\text{m}^2\right)\dfrac{\left(1.0\,\hat{i}+2.0\,\hat{j}\right)\times\hat{r}}{r^2}$ and evaluate $\vec{B}(3.0\,\text{m},6.0\,\text{m})$:

$$\vec{B}(3.0\,\text{m},6.0\,\text{m}) = \left(1.60\times10^{-24}\,\text{T}\cdot\text{m}^2\right)\frac{\left(1.0\,\hat{i}+2.0\,\hat{j}\right)\times\hat{j}}{(2.0\,\text{m})^2}$$

$$= \left(1.60\times10^{-24}\,\text{T}\cdot\text{m}^2\right)\left(\frac{\hat{k}}{4.0\,\text{m}^2}\right) = \boxed{\left(4.0\times10^{-25}\,\text{T}\right)\hat{k}}$$

16 •• In a pre–quantum-mechanical model of the hydrogen atom, an electron orbits a proton at a radius of 5.29×10^{-11} m. According to this model, what is the magnitude of the magnetic field at the proton due to the orbital motion of the electron? Neglect any motion of the proton.

Picture the Problem The centripetal force acting on the orbiting electron is the Coulomb force between the electron and the proton. We can apply Newton's second law to the electron to find its orbital speed and then use the expression for the magnetic field of a moving charge to find *B*.

Express the magnetic field due to the motion of the electron:

$$B = \frac{\mu_0}{4\pi}\frac{ev}{r^2}$$

Apply $\sum F_{\text{radial}} = ma_{\text{c}}$ to the electron:

$$\frac{ke^2}{r^2} = m\frac{v^2}{r} \Rightarrow v = \sqrt{\frac{ke^2}{mr}}$$

Substitute for *v* in the expression for *B* and simplify to obtain:

$$B = \frac{\mu_0}{4\pi}\frac{e}{r^2}\sqrt{\frac{ke^2}{mr}} = \frac{\mu_0 e^2}{4\pi r^2}\sqrt{\frac{k}{mr}}$$

Substitute numerical values and evaluate B:

$$B = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(1.602\times10^{-19}\ \text{C}\right)^2}{4\pi\left(5.29\times10^{-11}\ \text{m}\right)^2}\sqrt{\frac{8.988\times10^{9}\ \text{N}\cdot\text{m}^2/\text{C}^2}{\left(9.109\times10^{-31}\ \text{kg}\right)\left(5.29\times10^{-11}\ \text{m}\right)}}$$
$$= \boxed{12.5\,\text{T}}$$

17 •• Two equal point charges q are, at some instant, located at (0, 0, 0) and at (0, b, 0). They are both moving with speed v in the $+x$ direction (assume $v \ll c$). Find the ratio of the magnitude of the magnetic force to the magnitude of the electric force on each charge.

Picture the Problem We can find the ratio of the magnitudes of the magnetic and electrostatic forces by using the expression for the magnetic field of a moving charge and Coulomb's law. Note that $\vec{v}$ and $\vec{r}$, where $\vec{r}$ is the vector from one charge to the other, are at right angles. The field $\vec{B}$ due to the charge at the origin at the location (0, b, 0) is perpendicular to $\vec{v}$ and $\vec{r}$.

Express the magnitude of the magnetic force on the moving charge at (0, b, 0):

$$F_B = qvB = \frac{\mu_0}{4\pi}\frac{q^2v^2}{b^2}$$

and, applying the right hand rule, we find that the direction of the force is toward the charge at the origin; i.e., the magnetic force between the two moving charges is attractive.

Express the magnitude of the repulsive electrostatic interaction between the two charges:

$$F_E = \frac{1}{4\pi\in_0}\frac{q^2}{b^2}$$

Express the ratio of F_B to F_E and simplify to obtain:

$$\frac{F_B}{F_E} = \frac{\dfrac{\mu_0}{4\pi}\dfrac{q^2v^2}{b^2}}{\dfrac{1}{4\pi\in_0}\dfrac{q^2}{b^2}} = \boxed{\in_0\mu_0v^2}$$

The Magnetic Field Using the Biot–Savart Law

18 • A small current element at the origin has a length of 2.0 mm and carries a current of 2.0 A in the $+z$ direction. Find the magnetic field due to the current element: (a) on the x axis at x = 3.0 m, (b) on the x axis at x = –6.0 m, (c) on the z axis at z = 3.0 m, and (d) on the y axis at y = 3.0 m.

Picture the Problem We can substitute for I and $d\vec{\ell} \approx \Delta\vec{\ell}$ in the Biot-Savart relationship ($d\vec{B} = \frac{\mu_0}{4\pi}\frac{Id\vec{\ell}\times\hat{r}}{r^2}$), evaluate r and $\hat{r}$ for each of the points of interest, and substitute to find $d\vec{B}$.

Express the Biot-Savart law for the given current element:

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{I\vec{\ell}\times\hat{r}}{r^2} = \left(10^{-7}\ \text{N/A}^2\right)\frac{(2.0\,\text{A})(2.0\,\text{mm})\hat{k}\times\hat{r}}{r^2} = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k}\times\hat{r}}{r^2}$$

(*a*) Find r and $\hat{r}$ for the point whose coordinates are (3.0 m, 0, 0):

$\vec{r} = (3.0\,\text{m})\hat{i}$, $r = 3.0\,\text{m}$, and $\hat{r} = \hat{i}$

Evaluate $\vec{B}$ at (3.0 m, 0, 0):

$$\vec{B}(3.0\,\text{m},0,0) = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k}\times\hat{i}}{(3.0\,\text{m})^2} = \boxed{(44\,\text{pT})\hat{j}}$$

(*b*) Find r and $\hat{r}$ for the point whose coordinates are (–6.0 m, 0, 0):

$\vec{r} = -(6.0\,\text{m})\hat{i}$, $r = 6.0\,\text{m}$, and $\hat{r} = -\hat{i}$

Evaluate $\vec{B}$ at (–6.0 m, 0, 0):

$$\vec{B}(-6.0\,\text{m},0,0) = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\cdot\frac{\hat{k}\times\left(-\hat{i}\right)}{(6.0\,\text{m})^2} = \boxed{-(11\,\text{pT})\hat{j}}$$

(*c*) Find r and $\hat{r}$ for the point whose coordinates are (0, 0, 3.0 m):

$\vec{r} = (3.0\,\text{m})\hat{k}$, $r = 3.0\,\text{m}$, and $\hat{r} = \hat{k}$

Evaluate $\vec{B}$ at (0, 0, 3.0 m):

$$\vec{B}(0,0,3.0\,\text{m}) = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k}\times\hat{k}}{(3.0\,\text{m})^2} = \boxed{0}$$

(*d*) Find r and $\hat{r}$ for the point whose coordinates are (0, 3.0 m, 0):

$\vec{r} = (3.0\,\text{m})\hat{j}$, $r = 3.0\,\text{m}$, and $\hat{r} = \hat{j}$

Evaluate $\vec{B}$ at (0, 3.0 m, 0):

$$\vec{B}(0,3.0\,\text{m},0) = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k}\times\hat{j}}{(3.0\,\text{m})^2} = \boxed{-(44\,\text{pT})\hat{i}}$$

19 • **[SSM]** A small current element at the origin has a length of 2.0 mm and carries a current of 2.0 A in the +z direction. Find the magnitude and direction of the magnetic field due to the current element at the point (0, 3.0 m, 4.0 m).

Picture the Problem We can substitute for I and $d\vec{\ell} \approx \Delta\vec{\ell}$ in the Biot-Savart law ($d\vec{B} = \frac{\mu_0}{4\pi}\frac{Id\vec{\ell}\times\hat{r}}{r^2}$), evaluate r and $\hat{r}$ for (0, 3.0 m, 4.0 m), and substitute to find $d\vec{B}$.

The Biot-Savart law for the given current element is given by:

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{I\vec{\ell}\times\hat{r}}{r^2}$$

Substituting numerical values yields:

$$\vec{B} = \left(1.0\times10^{-7}\ \text{N/A}^2\right)\frac{(2.0\,\text{A})(2.0\,\text{mm})\hat{k}\times\hat{r}}{r^2} = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k}\times\hat{r}}{r^2}$$

Find r and $\hat{r}$ for the point whose coordinates are (0, 3.0 m, 4.0 m):

$$\vec{r} = (3.0\,\text{m})\hat{j} + (4.0\,\text{m})\hat{k},$$

$$r = 5.0\,\text{m},\ \text{and}\ \hat{r} = \frac{3}{5}\hat{j} + \frac{4}{5}\hat{k}$$

Evaluate $\vec{B}$ at (0, 3.0 m, 4.0 m):

$$\vec{B}(0,3.0\,\text{m},4.0\,\text{m}) = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k}\times\left(\frac{3}{5}\hat{j}+\frac{4}{5}\hat{k}\right)}{(5.0\,\text{m})^2} = \boxed{-(9.6\,\text{pT})\hat{i}}$$

20 • A small current element at the origin has a length of 2.0 mm and carries a current of 2.0 A in the +z direction. Find the magnitude of the magnetic field due to this element and indicate its direction on a diagram at (*a*) x = 2.0 m, y = 4.0 m, z = 0 and (*b*) x = 2.0 m, y = 0, z = 4.0 m.

Picture the Problem We can substitute for I and $d\vec{\ell} \approx \Delta\vec{\ell}$ in the Biot-Savart law ($d\vec{B} = \frac{\mu_0}{4\pi}\frac{Id\vec{\ell}\times\hat{r}}{r^2}$), evaluate r and $\hat{r}$ for the given points, and substitute to find $d\vec{B}$.

Apply the Biot-Savart law to the given current element to obtain:

$$d\vec{B} = \frac{\mu_0}{4\pi}\frac{I d\vec{\ell} \times \hat{r}}{r^2} = \left(10^{-7}\ \text{N/A}^2\right)\frac{(2.0\,\text{A})(2.0\,\text{mm})\hat{k} \times \hat{r}}{r^2} = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k} \times \hat{r}}{r^2}$$

(*a*) Find r and $\hat{r}$ for the point whose coordinates are (2.0 m, 4.0 m, 0):

$$\vec{r} = (2.0\,\text{m})\hat{i} + (4.0\,\text{m})\hat{j},$$

$$r = 2.0\sqrt{5}\,\text{m},$$

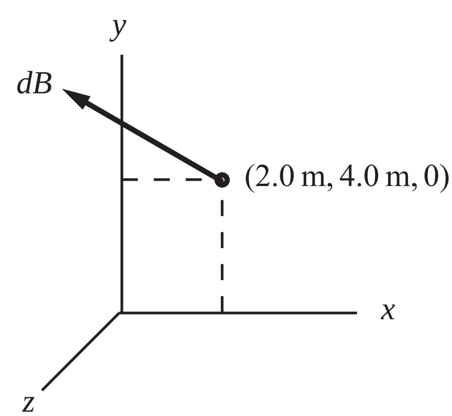
and

$$\hat{r} = \frac{2.0}{2\sqrt{5}}\hat{i} + \frac{4.0}{2\sqrt{5}}\hat{j} = \frac{1.0}{\sqrt{5}}\hat{i} + \frac{2.0}{\sqrt{5}}\hat{j}$$

Evaluate $d\vec{B}$ at (2.0 m, 4.0 m, 0):

$$d\vec{B}(2.0\,\text{m}, 4.0\,\text{m}, 0) = \left(0.400\,\text{nT}\cdot\text{m}^2\right)\frac{\hat{k} \times \left(\frac{1}{\sqrt{5}}\hat{i} + \frac{2}{\sqrt{5}}\hat{j}\right)}{\left(2\sqrt{5}\,\text{m}\right)^2} = \boxed{-(18\,\text{pT})\hat{i} + (8.9\,\text{pT})\hat{j}}$$

The diagram is shown to the right:



(*b*) Find r and $\hat{\boldsymbol{r}}$ for the point whose coordinates are (2.0 m, 0, 4.0 m):

$$\vec{\boldsymbol{r}} = (2.0\,\text{m})\hat{\boldsymbol{i}} + (4.0\,\text{m})\hat{\boldsymbol{k}}\,,$$

$$r = 2.0\sqrt{5}\,\text{m}\,,$$

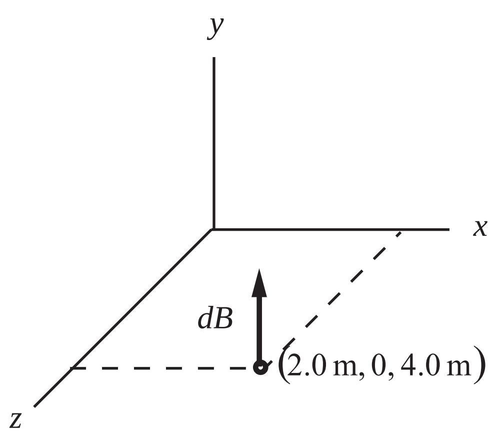
and

$$\hat{\boldsymbol{r}} = \frac{2.0}{2.0\sqrt{5}}\hat{\boldsymbol{i}} + \frac{4.0}{2.0\sqrt{5}}\hat{\boldsymbol{k}} = \frac{1.0}{\sqrt{5}}\hat{\boldsymbol{i}} + \frac{2.0}{\sqrt{5}}\hat{\boldsymbol{k}}$$

Evaluate $d\vec{\boldsymbol{B}}$ at (2.0 m, 0, 4.0 m):

$$d\vec{\boldsymbol{B}}(2.0\,\text{m},0,4.0\,\text{m}) = (0.400\,\text{nT}\cdot\text{m}^2)\frac{\hat{\boldsymbol{k}}\times\left(\frac{1.0}{\sqrt{5}}\hat{\boldsymbol{i}} + \frac{2.0}{\sqrt{5}}\hat{\boldsymbol{k}}\right)}{\left(2.0\sqrt{5}\,\text{m}\right)^2} = \boxed{(8.9\,\text{pT})\hat{\boldsymbol{j}}}$$

The diagram is shown to the right:



The Magnetic Field Due to Current Loops and Coils

21 • A single conducting loop has a radius equal to 3.0 cm and carries a current equal to 2.6 A. What is the magnitude of the magnetic field on the line through the center of the loop and perpendicular to the plane of the loop (*a*) the center of the loop, (*b*) 1.0 cm from the center, (*c*) 2.0 cm from the center, and (*d*) 35 cm from the center?

Picture the Problem We can use $B_x = \frac{\mu_0}{4\pi}\frac{2\pi R^2 I}{\left(x^2 + R^2\right)^{3/2}}$ to find B on the axis of the current loop.

B on the axis of a current loop is given by:

$$B_x = \frac{\mu_0}{4\pi}\frac{2\pi R^2 I}{\left(x^2 + R^2\right)^{3/2}}$$

Substitute numerical values to obtain:

$$B_x = \left(10^{-7}\ \text{N/A}^2\right)\frac{2\pi(0.030\,\text{m})^2(2.6\,\text{A})}{\left(x^2+(0.030\,\text{m})^2\right)^{3/2}} = \frac{1.470\times10^{-9}\ \text{T}\cdot\text{m}^3}{\left(x^2+(0.030\,\text{m})^2\right)^{3/2}}$$

(*a*) Evaluate *B* at the center of the loop:

$$B(0) = \frac{1.470\times10^{-9}\ \text{T}\cdot\text{m}^3}{\left(0+(0.030\,\text{m})^2\right)^{3/2}} = \boxed{54\,\mu\text{T}}$$

(*b*) Evaluate *B* at $x = 1.0$ cm:

$$B(0.010\,\text{m}) = \frac{1.470\times10^{-9}\ \text{T}\cdot\text{m}^3}{\left((0.010\,\text{m})^2+(0.030\,\text{m})^2\right)^{3/2}} = \boxed{46\,\mu\text{T}}$$

(*c*) Evaluate *B* at $x = 2.0$ cm:

$$B(0.020\,\text{m}) = \frac{1.470\times10^{-9}\ \text{T}\cdot\text{m}^3}{\left((0.020\,\text{m})^2+(0.030\,\text{m})^2\right)^{3/2}} = \boxed{31\,\mu\text{T}}$$

(*d*) Evaluate *B* at $x = 35$ cm:

$$B(0.35\,\text{m}) = \frac{1.470\times10^{-9}\ \text{T}\cdot\text{m}^3}{\left((0.35\,\text{m})^2+(0.030\,\text{m})^2\right)^{3/2}} = \boxed{34\,\text{nT}}$$

22 ••• A pair of identical coils, each having a radius of 30 cm, are separated by a distance equal to their radii, that is 30 cm. Called *Helmholtz coils*, they are coaxial and carry equal currents in directions such that their axial fields are in the same direction. A feature of Helmholtz coils is that the resultant magnetic field in the region between the coils is very uniform. Assume the current in each is 15 A and there are 250 turns for each coil. Using a **spreadsheet** program calculate and graph the magnetic field as a function of *z,* the distance from the center of the coils along the common axis, for -30 cm $< z < +30$ cm. Over what range of *z* does the field vary by less than 20%?

Picture the Problem Let the origin be midway between the coils so that one of them is centered at $z = -R/2$ and the other is centered at $z = R/2$, where *R* is the radius of the coils. Let the numeral 1 denote the coil centered at $z = -R/2$ and the numeral 2 the coil centered at $z = R/2$. We can express the magnetic field in the region between the coils as the sum of the magnetic fields B_1 and B_2 due to the two coils.

The magnetic field on the z is the sum of the magnetic fields due to the currents in coils 1 and 2:

$$B_z = B_1(z) + B_2(z) \quad (1)$$

Express the magnetic field on the z axis due to the coil centered at $z = -R/2$:

$$B_1(z) = \frac{\mu_0 NR^2 I}{2\left[z + \left(\frac{1}{2}R\right)^2 + R^2\right]^{3/2}}$$

where N is the number of turns.

Express the magnetic field on the z axis due to the coil centered at $z = R/2$:

$$B_2(z) = \frac{\mu_0 NR^2 I}{2\left[\left(z - \frac{1}{2}R\right)^2 + R^2\right]^{3/2}}$$

Substitute for $B_1(z)$ and $B_2(z)$ in equation (1) to express the total magnetic field along the z axis:

$$\begin{aligned} B_z &= \frac{\mu_0 NR^2 I}{2\left[\left(z + \frac{1}{2}R\right)^2 + R^2\right]^{3/2}} + \frac{\mu_0 NR^2 I}{2\left[\left(z - \frac{1}{2}R\right)^2 + R^2\right]^{3/2}} \\ &= \frac{\mu_0 NR^2 I}{2}\left(\left[\left(z + \frac{1}{2}R\right)^2 + R^2\right]^{-3/2} + \left[\left(z - \frac{1}{2}R\right)^2 + R^2\right]^{-3/2}\right) \end{aligned}$$

The spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	1.13×10^{-7}	μ_0
B2	0.30	R

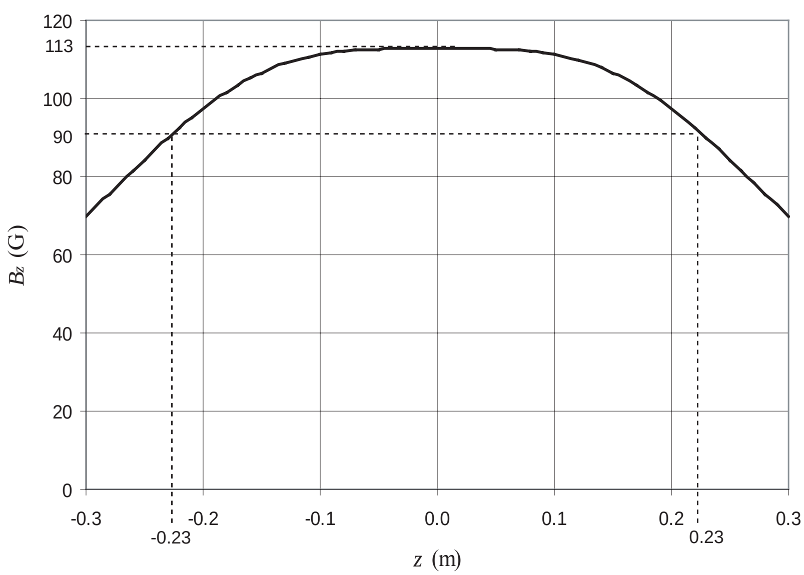
67	0.29	1.41E–03	5.86E–03	73
68	0.30	1.34E–03	5.63E–03	70

The following graph of B_z as a function of z was plotted using the data in the above table.



The maximum value of B_z is 113 G. Eighty percent of this maximum value is 90 G. We see that the field is within 20 percent of 113 G in the interval

$$\boxed{-0.23\,\text{m} < z < 0.23\,\text{m}.}$$

23 ••• A pair of Helmholtz coils that have radii R have their axes along the z axis (see Problem 22). One coil is in the $z=-\frac{1}{2}R$ plane and the second coil is in the $z=\frac{1}{2}R$ plane. Show that on the z axis at $z = 0$ $dB_z/dz = 0$, $d^2B_z/dz^2 = 0$, and $d^3B_z/dz^3 = 0$. (*Note:* These results show that the magnitude and direction of the magnetic field in the region to either side of the midpoint is approximately equal to the magnitude and direction of the magnetic field at the midpoint.)

Picture the Problem Let the numeral 1 denote the coil centered at $z=-\frac{1}{2}R$ and the numeral 2 the coil centered at $z=\frac{1}{2}R$. We can express the magnetic field strength in the region between the coils as the sum of the magnetic field strengths due to the two coils and then evaluate the derivatives of this function to show that $dB_z/dz = 0$, $d^2B_z/dz^2 = 0$, and $d^3B_z/dz^3 = 0$ at $z = 0$.

Express the magnetic field strength on the z axis due to the coil centered at $z=-\frac{1}{2}R$:

$$B_1(z)=\frac{\mu_0 NR^2 I}{2z_1^3}$$

where $z_1=\sqrt{\left(z+\frac{1}{2}R\right)^2+R^2}$ and N is the number of turns and.

Express the magnetic field strength on the z axis due to the coil centered at $z=\frac{1}{2}R$:

$$B_2(x)=\frac{\mu_0 NR^2 I}{2z_2^3}$$

where $z_2=\sqrt{\left(z-\frac{1}{2}R\right)^2+R^2}$

Add these equations to express the total magnetic field along the x axis:

$$B_z(z)=B_1(z)+B_2(z)=\frac{\mu_0 NR^2 I}{2z_1^3}+\frac{\mu_0 NR^2 I}{2z_2^3}=\frac{\mu_0 NR^2 I}{2}\left(z_1^{-3}+z_2^{-3}\right)$$

Differentiate B_z with respect to z to obtain:

$$\frac{dB_z}{dz}=\frac{\mu_0 NR^2 I}{2}\frac{d}{dz}\left(z_1^{-3}+z_2^{-3}\right)$$
$$=\frac{\mu_0 NR^2 I}{2}\left(-3z_1^{-4}\frac{dz_1}{dz}-3z_2^{-4}\frac{dz_2}{dz}\right)$$

Because $z_1=\sqrt{\left(z+\frac{1}{2}R\right)^2+R^2}$:

$$\frac{dz_1}{dz}=\frac{1}{2}\left[\left(z+\frac{1}{2}R\right)^2+R^2\right]^{-1/2}\left[2\left(z+\frac{1}{2}R\right)\right]$$
$$=\frac{z+\frac{1}{2}R}{z_1}$$

Because $z_2 = \sqrt{\left(z - \frac{1}{2}R\right)^2 + R^2}$:

$$\frac{dz_2}{dz} = \tfrac{1}{2}\left[\left(z - \tfrac{1}{2}R\right)^2 + R^2\right]^{-1/2}\left[2\left(z - \tfrac{1}{2}R\right)\right] = \frac{z - \frac{1}{2}R}{z_2}$$

Evaluating $z_1(0)$ and $z_2(0)$ yields:

$$z_1(0) = \sqrt{\left(\tfrac{1}{2}R\right)^2 + R^2} = \left(\tfrac{5}{4}R^2\right)^{1/2}$$

and

$$z_2(0) = \sqrt{\left(\tfrac{1}{2}R\right)^2 + R^2} = \left(\tfrac{5}{4}R^2\right)^{1/2}$$

Substituting for $\frac{dz_1}{dz}$ and $\frac{dz_2}{dz}$ in the expression for $\frac{dB_z}{dz}$ and simplifying yields:

$$\frac{dB_z}{dz} = \frac{\mu_0 NR^2 I}{2}\left[\left(-3z_1^{-4}\left(\frac{z + \frac{1}{2}R}{z_1}\right) + -3z_2^{-4}\left(\frac{z - \frac{1}{2}R}{z_2}\right)\right)\right] = \frac{\mu_0 NR^2 I}{2}\left[\frac{-3\left(z + \frac{1}{2}R\right)}{z_1^5} + \frac{-3\left(z - \frac{1}{2}R\right)}{z_2^5}\right]$$

Substitute for $z_1(0)$ and $z_2(0)$ and evaluate $\frac{dB_z}{dz}$ at $z = 0$:

$$\left.\frac{dB_z}{dz}\right|_{z=0} = \frac{\mu_0 NR^2 I}{2}\left(\frac{-3\left(\frac{1}{2}R\right)}{\left(\frac{5}{4}R^2\right)^{5/2}} + \frac{-3\left(-\frac{1}{2}R\right)}{\left(\frac{5}{4}R^2\right)^{5/2}}\right) = \boxed{0}$$

Differentiate $\frac{dB_z}{dz}$ with respect to z to obtain:

$$\frac{d^2B_z}{dz^2} = \frac{\mu_0 NR^2 I}{2}\frac{d}{dz}\left[\frac{-3\left(z + \frac{1}{2}R\right)}{z_1^5} + \frac{-3\left(z - \frac{1}{2}R\right)}{z_2^5}\right] = \frac{\mu_0 NR^2 I}{2}(-3)\left[\frac{1}{z_1^5} - \frac{5\left(z + \frac{1}{2}R\right)^2}{z_1^7} + \frac{1}{z_2^5} - \frac{5\left(z - \frac{1}{2}R\right)^2}{z_2^7}\right]$$

Evaluate $\frac{d^2B_z}{dz^2}$ at $z = 0$ to obtain:

$$\left.\frac{d^2B_z}{dz^2}\right|_{z=0} = \frac{\mu_0 NR^2 I}{2}(-3)\left[\frac{1}{\left(\frac{5}{4}R\right)^{5/2}} - \frac{5\left(\frac{1}{2}R\right)^2}{\left(\frac{5}{4}R\right)^{7/2}} + \frac{1}{\left(\frac{5}{4}R\right)^{5/2}} - \frac{5\left(-\frac{1}{2}R\right)^2}{\left(\frac{5}{4}R\right)^{7/2}}\right]$$

$$= \frac{\mu_0 NR^2 I}{2}(-3)\left[\frac{1}{\left(\frac{5}{4}R\right)^{5/2}} - \frac{\frac{5}{4}R^2}{\left(\frac{5}{4}R\right)^{7/2}} + \frac{1}{\left(\frac{5}{4}R\right)^{5/2}} - \frac{\frac{5}{4}R^2}{\left(\frac{5}{4}R\right)^{7/2}}\right]$$

$$= \frac{\mu_0 NR^2 I}{2}(-3)\left[\frac{1}{\left(\frac{5}{4}R\right)^{5/2}} - \frac{1}{\left(\frac{5}{4}R\right)^{5/2}} + \frac{1}{\left(\frac{5}{4}R\right)^{5/2}} - \frac{1}{\left(\frac{5}{4}R\right)^{5/2}}\right]$$

$$= \boxed{0}$$

Differentiate $\frac{d^2B_z}{dz^2}$ with respect to z to obtain:

$$\frac{d^3B_z}{dz^3} = \frac{\mu_0 NR^2 I}{2}(-3)\frac{d}{dz}\left[\frac{1}{z_1^5} - \frac{5\left(z+\frac{1}{2}R\right)^2}{z_1^7} + \frac{1}{z_2^5} - \frac{5\left(z-\frac{1}{2}R\right)^2}{z_2^7}\right]$$

$$= \frac{\mu_0 NR^2 I}{2}(-3)\left(\frac{35\left(z+\frac{1}{2}R\right)^3}{z_1^9} - \frac{15\left(z+\frac{1}{2}R\right)}{z_1^7} - \frac{15\left(z-\frac{1}{2}R\right)}{z_2^7} + \frac{35\left(z-\frac{1}{2}R\right)^3}{z_2^9}\right)$$

Evaluate $\frac{d^3B_z}{dz^3}$ at $z = 0$ to obtain:

$$\left.\frac{d^3B_z}{dz^3}\right|_{z=0} = \frac{\mu_0 NR^2 I}{2}(-3)\left(\frac{35\left(\frac{1}{2}R\right)^3}{z_1^9} - \frac{15\left(\frac{1}{2}R\right)}{z_1^7} - \frac{15\left(-\frac{1}{2}R\right)}{z_2^7} + \frac{35\left(-\frac{1}{2}R\right)^3}{z_2^9}\right)$$

$$= \frac{\mu_0 NR^2 I}{2}(-3)\left(\frac{35\left(\frac{1}{2}R\right)^3}{\left(\frac{5}{4}R^2\right)^{9/2}} - \frac{15\left(\frac{1}{2}R\right)}{\left(\frac{5}{4}R^2\right)^{7/2}} + \frac{15\left(\frac{1}{2}R\right)}{\left(\frac{5}{4}R^2\right)^{7/2}} - \frac{35\left(\frac{1}{2}R\right)^3}{\left(\frac{5}{4}R^2\right)^{9/2}}\right)$$

$$= \boxed{0}$$

24 ••• *Anti-Helmholtz* coils are used in many physics applications, such as laser cooling and trapping, where a field with a uniform gradient is desired. These coils have the same construction as a Helmholtz coil, except that the currents have opposite directions, so that the axial fields are in opposite directions, and the coil separation is $\sqrt{3}R$ rather than R. Graph the magnetic field as a function of z, the axial distance from the center of the coils, for an anti-Helmholtz coil using the same parameters as in Problem 22. Over what interval of

the z axis is dB_z/dz within one percent of its value at the midpoint between the coils?

Picture the Problem Let the origin be midway between the coils so that one of them is centered at $z=-\frac{\sqrt{3}}{2}R$ and the other is centered at $z=\frac{\sqrt{3}}{2}R$. Let the numeral 1 denote the coil centered at $z=-\frac{\sqrt{3}}{2}R$ and the numeral 2 the coil centered at $z=\frac{\sqrt{3}}{2}R$. We can express the magnetic field in the region between the coils as the difference of the magnetic fields B_1 and B_2 due to the two coils and use the two-point formula to approximate the slope of the graph of B_z as a function of z.

The magnetic field on the z is the difference between the magnetic fields due to the currents in coils 1 and 2:

$$B_z = B_1(z) - B_2(z) \qquad (1)$$

Express the magnetic field on the z axis due to the coil centered at $z=-R\sqrt{3}/2$:

$$B_1(z)=\frac{\mu_0 NR^2 I}{2\left[\left(z+\frac{\sqrt{3}}{2}R\right)^2+R^2\right]^{3/2}}$$

where N is the number of turns.

Express the magnetic field on the z axis due to the coil centered at $z=R\sqrt{3}/2$:

$$B_2(z)=\frac{\mu_0 NR^2 I}{2\left[\left(z-\frac{\sqrt{3}}{2}R\right)^2+R^2\right]^{3/2}}$$

Substitute for $B_1(z)$ and $B_2(z)$ in equation (1) to express the total magnetic field along the z axis:

$$\begin{aligned} B_z &= \frac{\mu_0 NR^2 I}{2\left[\left(z+\frac{\sqrt{3}}{2}R\right)^2+R^2\right]^{3/2}} - \frac{\mu_0 NR^2 I}{2\left[\left(z-\frac{\sqrt{3}}{2}R\right)^2+R^2\right]^{3/2}} \\ &= \frac{\mu_0 NR^2 I}{2}\left(\left[\left(z+\frac{\sqrt{3}}{2}R\right)^2+R^2\right]^{-3/2} - \left[\left(z-\frac{\sqrt{3}}{2}R\right)^2+R^2\right]^{-3/2}\right) \end{aligned} \qquad (1)$$

The spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

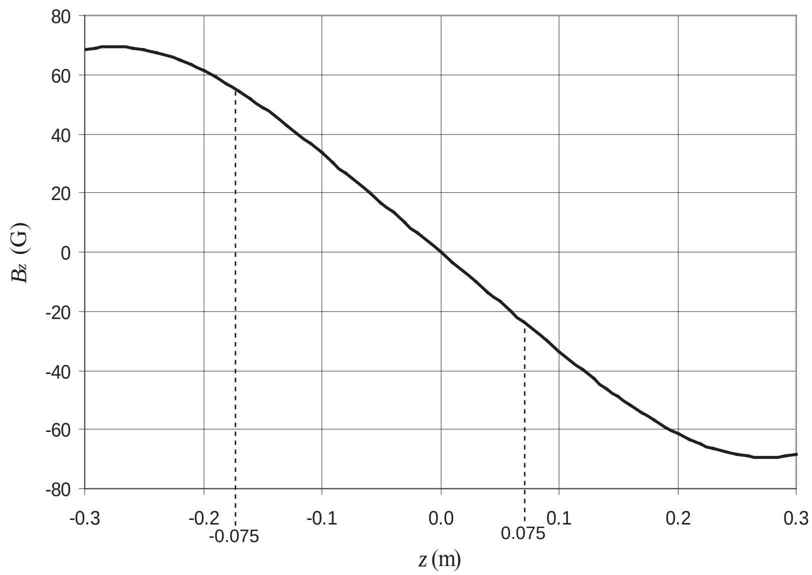
The following graph of B_z as a function of z was plotted using the data in the above table.



Inspection of the table reveals that the slope of the graph of B_z, evaluated at $z = 0$, is −337 G. 1% of this value corresponds approximately to $-0.075\text{ m} < z < 0.075\text{ m}$ or $\boxed{-0.25R < z < 0.25R}$.

The Magnetic Field Due to Straight-Line Currents

25 •• **[SSM]** If the currents are both in the $-x$ direction, find the magnetic field at the following points on the y axis: (a) y = –3.0 cm, (b) y = 0, (c) y = +3.0 cm, and (d) y = +9.0 cm.

Picture the Problem Let + denote the wire (and current) at y = +6.0 cm and − the wire (and current) at y = −6.0 cm. We can use $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$ to find the magnetic field due to each of the current-carrying wires and superimpose the magnetic fields due to the currents in these wires to find B at the given points on the y axis. We can apply the right-hand rule to find the direction of each of the fields and, hence, of $\vec{B}$.

(*a*) Express the resultant magnetic field at $y = -3.0$ cm:

$$\vec{B}(-3.0\,\text{cm}) = \vec{B}_+(-3.0\,\text{cm}) + \vec{B}_-(-3.0\,\text{cm}) \qquad (1)$$

Find the magnitudes of the magnetic fields at $y = -3.0$ cm due to each wire:

$$B_+(-3.0\,\text{cm}) = \left(10^{-7}\,\text{T}\cdot\text{m/A}\right)\frac{2(20\,\text{A})}{0.090\,\text{m}} = 44.4\,\mu\text{T}$$

and

$$B_-(-3.0\,\text{cm}) = \left(10^{-7}\,\text{T}\cdot\text{m/A}\right)\frac{2(20\,\text{A})}{0.030\,\text{m}} = 133\,\mu\text{T}$$

Apply the right-hand rule to find the directions of $\vec{B}_+$ and $\vec{B}_-$:

$$\vec{B}_+(-3.0\,\text{cm}) = (44.4\,\mu\text{T})\hat{k}$$

and

$$\vec{B}_-(-3.0\,\text{cm}) = -(133\,\mu\text{T})\hat{k}$$

Substituting in equation (1) yields:

$$\vec{B}(-3.0\,\text{cm}) = (44.4\,\mu\text{T})\hat{k} - (133\,\mu\text{T})\hat{k} = \boxed{-(89\,\mu\text{T})\hat{k}}$$

(*b*) Express the resultant magnetic field at $y = 0$:

$$\vec{B}(0) = \vec{B}_+(0) + \vec{B}_-(0)$$

Because $\vec{B}_+(0) = -\vec{B}_-(0)$:

$$\vec{B}(0) = \boxed{0}$$

(*c*) Proceed as in (*a*) to obtain:

$$\vec{B}_+(3.0\,\text{cm}) = (133\,\mu\text{T})\hat{k}\,,$$

$$\vec{B}_-(3.0\,\text{cm}) = -(44.4\,\mu\text{T})\hat{k}\,,$$

and

$$\vec{B}(3.0\,\text{cm}) = (133\,\mu\text{T})\hat{k} - (44.4\,\mu\text{T})\hat{k} = \boxed{(89\,\mu\text{T})\hat{k}}$$

(*d*) Proceed as in (*a*) with $y = 9.0$ cm to obtain:

$$\vec{B}_+(9.0\,\text{cm}) = -(133\,\mu\text{T})\hat{k}\,,$$

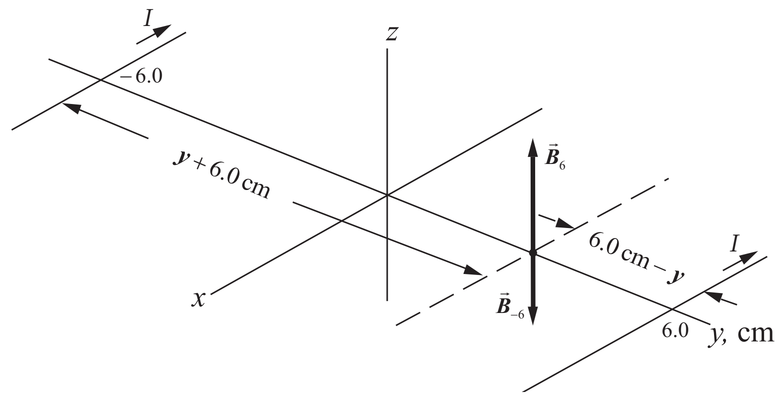
$$\vec{B}_-(9.0\,\text{cm}) = -(26.7\,\mu\text{T})\hat{k}\,,$$

and

$$\vec{B}(9.0\,\text{cm}) = -(133\,\mu\text{T})\hat{k} - (26.7\,\mu\text{T})\hat{k} = \boxed{-(160\,\mu\text{T})\hat{k}}$$

26 •• Using a **spreadsheet** program or graphing calculator, graph B_z versus y when both currents are in the $-x$ direction.

Picture the Problem The diagram shows the two wires with the currents flowing in the negative x direction. We can use the expression for B due to a long, straight wire to express the difference of the fields due to the two currents. We'll denote each field by the subscript identifying the position of each wire.



The field due to the current in the wire located at $y = 6.0$ cm is:

$$B_6 = \frac{\mu_0}{4\pi}\frac{2I}{0.060\,\text{m} - y}$$

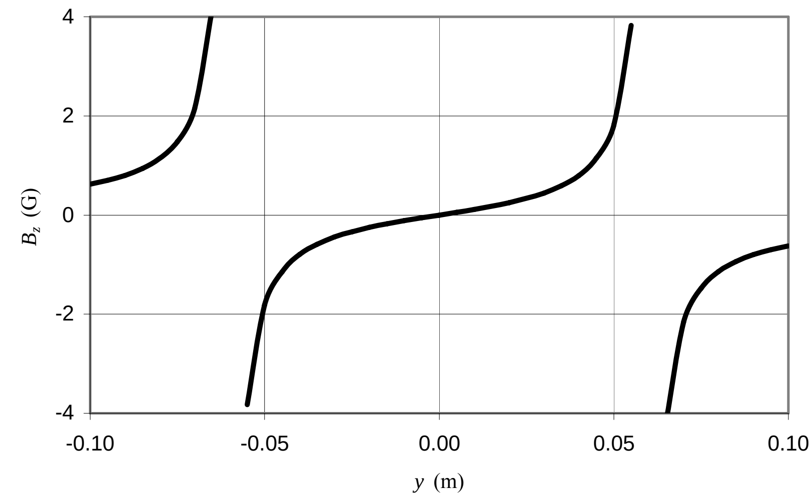
The field due to the current in the wire located at $y = -6.0$ cm is:

$$B_{-6} = \frac{\mu_0}{4\pi}\frac{2I}{0.060\,\text{m} + y}$$

The resultant field B_z is the difference between B_6 and B_{-6}:

$$\begin{aligned} B_z = B_6 - B_{-6} &= \frac{\mu_0}{4\pi}\frac{I}{0.060\,\text{m} - y} - \frac{\mu_0}{4\pi}\frac{I}{0.060\,\text{m} - y} \\ &= \frac{\mu_0 I}{4\pi}\left(\frac{1}{0.060\,\text{m} - y} - \frac{1}{0.060\,\text{m} + y}\right) \end{aligned}$$

The following graph of B_z as a function of y was plotted using a spreadsheet program:



27 •• The current in the wire at y = –6.0 cm is in the –x direction and the current in the wire at y = +6.0 cm is in the +x direction. Find the magnetic field at the following points on the y axis: (a) y = –3.0 cm, (b) y = 0, (c) y = +3.0 cm, and (d) y = +9.0 cm.

Picture the Problem Let + denote the wire (and current) at y = +6 cm and − the wire (and current) at y = –6.0 cm. We can use $B=\frac{\mu_0}{4\pi}\frac{2I}{R}$ to find the magnetic field due to each of the current carrying wires and superimpose the magnetic fields due to the currents in the wires to find B at the given points on the y axis. We can apply the right-hand rule to find the direction of each of the fields and, hence, of $\vec{B}$.

(a) Express the resultant magnetic field at $y = -3.0$ cm:

$$\vec{B}(-3.0\,\text{cm}) = \vec{B}_+(-3.0\,\text{cm}) + \vec{B}_-(-3.0\,\text{cm}) \quad (1)$$

Find the magnitudes of the magnetic fields at $y = -3.0$ cm due to each wire:

$$B_+(-3.0\,\text{cm}) = \left(10^{-7}\,\text{T}\cdot\text{m/A}\right)\frac{2(20\,\text{A})}{0.090\,\text{m}} = 44.4\,\mu\text{T}$$

and

$$B_-(-3.0\,\text{cm}) = \left(10^{-7}\,\text{T}\cdot\text{m/A}\right)\frac{2(20\,\text{A})}{0.030\,\text{m}} = 133\,\mu\text{T}$$

Apply the right-hand rule to find the directions of $\vec{B}_+$ and $\vec{B}_-$:

$$\vec{B}_+(-3.0\,\text{cm}) = -(44.4\,\mu\text{T})\hat{k}$$
and
$$\vec{B}_-(-3.0\,\text{cm}) = -(133\,\mu\text{T})\hat{k}$$

Substituting in equation (1) yields:

$$\vec{B}(-3.0\,\text{cm}) = -(44.4\,\mu\text{T})\hat{k} - (133\,\mu\text{T})\hat{k} = \boxed{-(0.18\,\text{mT})\hat{k}}$$

(*b*) Express the resultant magnetic field at $y = 0$:

$$\vec{B}(0) = \vec{B}_+(0) + \vec{B}_-(0)$$

Find the magnitudes of the magnetic fields at $y = 0$ cm due to each wire:

$$B_+(0) = \left(10^{-7}\ \text{T}\cdot\text{m/A}\right)\frac{2(20\,\text{A})}{0.060\,\text{m}} = 66.7\,\mu\text{T}$$
and
$$B_-(0) = \left(10^{-7}\ \text{T}\cdot\text{m/A}\right)\frac{2(20\,\text{A})}{0.060\,\text{m}} = 66.7\,\mu\text{T}$$

Apply the right-hand rule to find the directions of $\vec{B}_+$ and $\vec{B}_-$:

$$\vec{B}_+(0) = -(66.7\,\mu\text{T})\hat{k}$$
and
$$\vec{B}_-(0) = -(66.7\,\mu\text{T})\hat{k}$$

Substitute to obtain:

$$\vec{B}(0) = -(66.7\,\mu\text{T})\hat{k} - (66.7\,\mu\text{T})\hat{k} = \boxed{-(0.13\,\text{mT})\hat{k}}$$

(*c*) Proceed as in (*a*) with $y = +3.0$ cm to obtain:

$$\vec{B}_+(3.0\,\text{cm}) = -(133\,\mu\text{T})\hat{k},$$
$$\vec{B}_-(3.0\,\text{cm}) = -(44.4\,\mu\text{T})\hat{k},$$
and
$$\vec{B}(3.0\,\text{cm}) = -(133\,\mu\text{T})\hat{k} - (44.4\,\mu\text{T})\hat{k} = \boxed{-(0.18\,\text{mT})\hat{k}}$$

(*d*) Proceed as in (*a*) with $y = +9.0$ m to obtain:

$$\vec{B}_+(9.0\,\text{cm}) = (133\,\mu\text{T})\hat{k}\,,$$

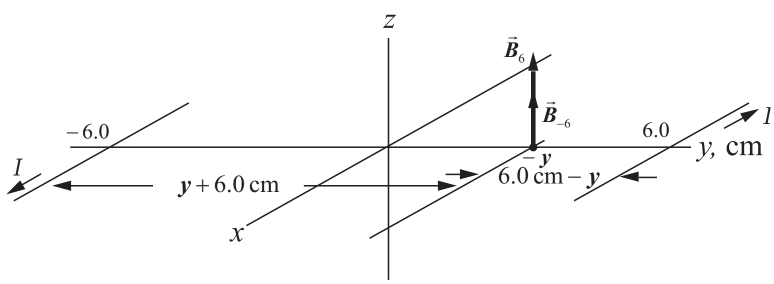
$$\vec{B}_-(9.0\,\text{cm}) = -(26.7\,\mu\text{T})\hat{k}\,,$$

and

$$\vec{B}(9.0\,\text{cm}) = (133\,\mu\text{T})\hat{k} - (26.7\,\mu\text{T})\hat{k} = \boxed{(0.11\,\text{mT})\hat{k}}$$

28 •• The current in the wire at $y = -6.0$ cm is in the $+x$ direction and the current in the wire at $y = +6.0$ cm is in the $-x$ direction. Using a **spreadsheet** program or graphing calculator, graph B_z versus y.

Picture the Problem The diagram shows the two wires with the currents flowing in the negative *x* direction. We can use the expression for *B* due to a long, straight wire to express the difference of the fields due to the two currents. We'll denote each field by the subscript identifying the position of each wire.



The field due to the current in the wire located at $y = 6.0$ cm is:

$$B_6 = \frac{\mu_0}{4\pi}\frac{2I}{0.060\,\text{m} - y}$$

The field due to the current in the wire located at $y = -6.0$ cm is:

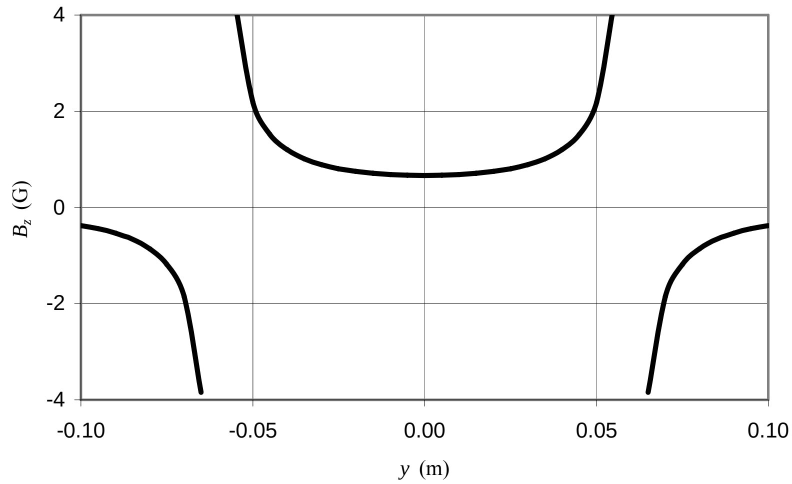
$$B_{-6} = \frac{\mu_0}{4\pi}\frac{2I}{0.060\,\text{m} + y}$$

The resultant field B_z is the sum of B_6 and B_{-6}:

$$B_z = B_6 + B_{-6} = \frac{\mu_0}{4\pi}\frac{I}{0.060\,\text{m} - y} + \frac{\mu_0}{4\pi}\frac{I}{0.060\,\text{m} - y}$$

$$= \frac{\mu_0 I}{4\pi}\left(\frac{1}{0.060\,\text{m} - y} + \frac{1}{0.060\,\text{m} + y}\right)$$

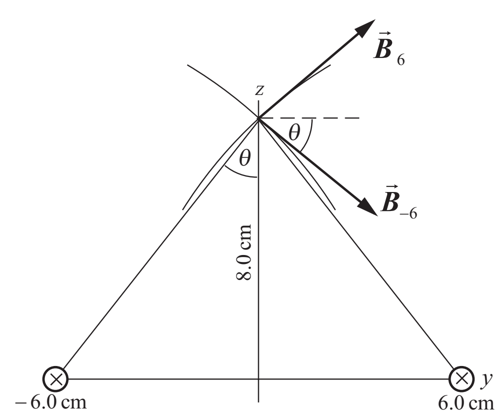
The following graph of B_z as a function of y was plotted using a spreadsheet program:



29 • Find the magnetic field on the z axis at z = +8.0 cm if (a) the currents are both in the $-x$ direction, and (b) the current in the wire at y = –6.0 cm is in the $-x$ direction and the current in the wire at y = +6.0 cm is in the $+x$ direction.

Picture the Problem Let + denote the wire (and current) at y = +6.0 cm and – the wire (and current) at y = –6.0 cm. We can use $B=\frac{\mu_0}{4\pi}\frac{2I}{R}$ to find the magnetic field due to each of the current carrying wires and superimpose the magnetic fields due to the currents in the wires to find B at the given points on the z axis.

(a) Apply the right-hand rule to show that, for the currents parallel and in the negative x direction, the directions of the fields are as shown to the right:



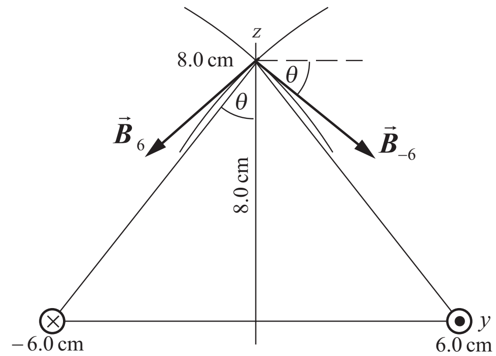
Express the magnitudes of the magnetic fields at z = +8.0 cm due to the current-carrying wires at y = –6.0 cm and y = +6.0 cm:

$$B_{z-}=B_{z+}=\left(10^{-7}\ \mathrm{T\cdot m/A}\right)\times\frac{2(20\ \mathrm{A})}{\sqrt{(0.060\ \mathrm{m})^2+(0.080\ \mathrm{m})^2}}$$
$$=40.0\ \mu\mathrm{T}$$

Noting that the z components add to zero, express the resultant magnetic field at $z = +8.0$ cm:

$$\vec{B}(8.0\,\text{cm}) = 2(40.0\,\mu\text{T})\cos\theta\,\hat{j} = 2(40.0\,\mu\text{T})(0.80)\,\hat{j} = \boxed{(64\,\mu\text{T})\,\hat{j}}$$

(b) Apply the right-hand rule to show that, for the currents antiparallel with the current in the wire at $y = -6.0$ cm in the negative x direction, the directions of the fields are as shown to the right:



Noting that the y components add to zero, express the resultant magnetic field at $z = +8.0$ cm:

$$\vec{B}(8.0\,\text{cm}) = -2(40.0\,\mu\text{T})\sin\theta\,\hat{k} = -2(40.0\,\mu\text{T})(0.60)\,\hat{k} = \boxed{-(48\,\mu\text{T})\,\hat{k}}$$

30 • Find the magnitude of the force per unit length exerted by one wire on the other.

Picture the Problem Let + denote the wire (and current) at $y = +6.0$ cm and − the wire (and current) at $y = -6.0$ cm. The forces per unit length the wires exert on each other are action and reaction forces and hence are equal in magnitude. We can use $F = I\ell B$ to express the force on either wire and $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$ to express the magnetic field at the location of either wire due to the current in the other.

Express the force exerted on either wire:

$$F = I\ell B$$

Express the magnetic field at either location due to the current in the wire at the other location:

$$B = \frac{\mu_0}{4\pi}\frac{2I}{R}$$

Substitute for B to obtain:

$$F = I\ell\left(\frac{\mu_0}{4\pi}\frac{2I}{R}\right) = \frac{2\ell\mu_0}{4\pi}\frac{I^2}{R}$$

Divide both sides of the equation by ℓ to obtain:

$$\frac{F}{\ell}=\frac{2\mu_0}{4\pi}\frac{I^2}{R}$$

Substitute numerical values and evaluate F/ℓ:

$$\frac{F}{\ell}=\frac{2\left(10^{-7}\ \mathrm{T\cdot m/A}\right)\left(20\ \mathrm{A}\right)^2}{0.12\ \mathrm{m}}=\boxed{0.67\ \mathrm{mN/m}}$$

31 • Two long, straight parallel wires 8.6 cm apart carry equal currents. The wires repel each other with a force per unit length of 3.6 nN/m. (*a*) Are the currents parallel or anti-parallel? Explain your answer. (*b*) Determine the current in each wire.

Picture the Problem We can use $\frac{F}{\ell}=\frac{2\mu_0}{4\pi}\frac{I^2}{R}$ to relate the force per unit length each current-carrying wire exerts on the other to their common current.

(*a*) Because the currents repel, they are antiparallel.

(*b*)The force per unit length experienced by each wire is given by:

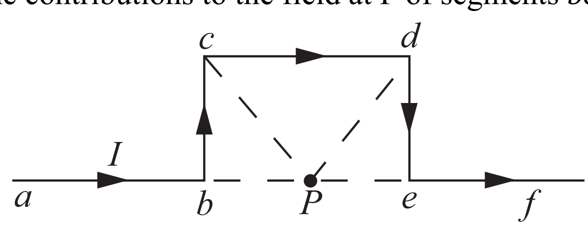
$$\frac{F}{\ell}=\frac{2\mu_0}{4\pi}\frac{I^2}{R}\Rightarrow I=\sqrt{\frac{4\pi R}{2\mu_0}\frac{F}{\ell}}$$

Substitute numerical values and evaluate I:

$$I=\sqrt{\frac{\left(8.6\ \mathrm{cm}\right)}{2\left(10^{-7}\ \mathrm{T\cdot m/A}\right)}\left(3.6\ \mathrm{nN/m}\right)}=\boxed{39\ \mathrm{mA}}$$

32 •• The current in the wire shown in Figure 27-52 is 8.0 A. Find the magnetic field at point *P*.

Picture the Problem Note that the current segments *a*-*b* and *e*-*f* do not contribute to the magnetic field at point *P*. The current in the segments *b*-*c*, *c*-*d*, and *d*-*e* result in a magnetic field at *P* that points into the plane of the paper. Note that the angles *bPc* and *ePd* are 45° and use the expression for *B* due to a straight wire segment to find the contributions to the field at P of segments *bc*, *cd*, and *de*.



Express the resultant magnetic field at *P*:

$$B = B_{bc} + B_{cd} + B_{de}$$

Express the magnetic field due to a straight line segment:

$$B = \frac{\mu_0}{4\pi}\frac{I}{R}\left(\sin\theta_1 + \sin\theta_2\right) \qquad (1)$$

Use equation (1) to express B_{bc} and B_{de}:

$$B_{bc} = \frac{\mu_0}{4\pi}\frac{I}{R}\left(\sin 45° + \sin 0°\right) = \frac{\mu_0}{4\pi}\frac{I}{R}\sin 45°$$

Use equation (1) to express B_{cd}:

$$B_{cd} = \frac{\mu_0}{4\pi}\frac{I}{R}\left(\sin 45° + \sin 45°\right) = 2\frac{\mu_0}{4\pi}\frac{I}{R}\sin 45°$$

Substitute to obtain:

$$B = \frac{\mu_0}{4\pi}\frac{I}{R}\sin 45° + 2\frac{\mu_0}{4\pi}\frac{I}{R}\sin 45° + \frac{\mu_0}{4\pi}\frac{I}{R}\sin 45° = 4\frac{\mu_0}{4\pi}\frac{I}{R}\sin 45°$$

Substitute numerical values and evaluate *B*:

$$B = 4\left(10^{-7}\ \text{T}\cdot\text{m/A}\right)\frac{8.0\,\text{A}}{0.010\,\text{m}}\sin 45° = \boxed{0.23\,\text{mT into the page}}$$

33 •• [SSM] As a student technician, you are preparing a lecture demonstration on "magnetic suspension." You have a 16-cm long straight rigid wire that will be suspended by flexible conductive lightweight leads above a long straight wire. Currents that are equal but are in opposite directions will be established in the two wires so the 16-cm wire "floats" a distance *h* above the long wire with no tension in its suspension leads. If the mass of the 16-cm wire is 14 g and if *h* (the distance between the central axes of the two wires) is 1.5 mm, what should their common current be?

Picture the Problem The forces acting on the wire are the upward magnetic force F_B and the downward gravitational force *mg*, where *m* is the mass of the wire. We can use a condition for translational equilibrium and the expression for the force per unit length between parallel current-carrying wires to relate the required current to the mass of the wire, its length, and the separation of the two wires.

Apply $\sum F_y = 0$ to the floating wire to obtain:

$$F_B - mg = 0$$

Express the repulsive force acting on the upper wire:

$$F_B = 2\frac{\mu_0}{4\pi}\frac{I^2\ell}{R}$$

Substitute to obtain:

$$2\frac{\mu_0}{4\pi}\frac{I^2\ell}{R} - mg = 0 \Rightarrow I = \sqrt{\frac{4\pi mgR}{2\mu_0\ell}}$$

Substitute numerical values and evaluate I:

$$I = \sqrt{\frac{(14\times10^{-3}\text{ kg})(9.81\text{m/s}^2)(1.5\times10^{-3}\text{ m})}{2(10^{-7}\text{ T}\cdot\text{m/A})(0.16\text{m})}} = \boxed{80\text{A}}$$

34 •• Three long, parallel straight wires pass through the vertices of an equilateral triangle that has sides equal to 10 cm, as shown in Figure 27-53. The dot indicates that the direction of the current is out of the page and a cross indicates that the direction of the current is into the page. If each current is 15 A, find (*a*) the magnetic field at the location of the upper wire due to the currents in the two lower wires and (*b*) the force per unit length on the upper wire.

Picture the Problem (*a*) Choose a coordinate system in which the +*x* direction is to the right and the +*y* direction is upward. We can use the right-hand rule to determine the directions of the magnetic fields at the upper wire due to the currents in the two lower wires and use $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$ to find the magnitude of the resultant field due to these currents. (*b*) Note that the forces on the upper wire are away from and directed along the lines to the lower wire and that their horizontal components cancel. We can use the expression for the magnetic force on a current-carrying wire to find the force per unit length on the upper wire.

(*a*) Noting, from the geometry of the wires, the magnetic field vectors both are at an angle of 30° with the horizontal and that their *y* components cancel, express the resultant magnetic field:

$$\vec{B} = 2\left(\frac{\mu_0}{4\pi}\frac{2I}{R}\cos 30°\right)\hat{i}$$

Substitute numerical values and evaluate B:

$$\vec{B} = 2\left(10^{-7}\ \text{T}\cdot\text{m/A}\right)\frac{2(15\,\text{A})}{0.10\,\text{m}}\cos 30°\hat{i}$$

$$= \boxed{(52\,\mu\text{T})\hat{i}}$$

That is, the magnitude of the magnetic field is 52 μT and its direction is to the right.

(*b*) Express the force per unit length each of the lower wires exerts on the upper wire:

$$\vec{F} = I\left(\vec{\ell}\times\vec{B}\right) = I\left(\ell\hat{k}\times B\hat{i}\right) = I\ell B\sin 90°\hat{j}$$

and

$$\frac{\vec{F}}{\ell} = IB\sin 90°\hat{j}$$

Substitute numerical values and evaluate $\frac{\vec{F}}{\ell}$:

$$\frac{\vec{F}}{\ell} = (15\,\text{A})(52\,\mu\text{T})\hat{j}$$

$$= \boxed{\left(7.8\times10^{-4}\ \text{N/m}\right)\hat{j}}$$

That is, the magnitude of the force per unit length on the upper wire is 7.8×10^{-4} N/m and the direction of this force is up the page.

35 •• Rework Problem 34 with the current in the lower right corner of Figure 27- 53 reversed.

Picture the Problem (*a*) Choose a coordinate system in which the +*x* direction is to the right and the +*y* direction is upward. We can use the right-hand rule to determine the directions of the magnetic fields at the upper wire due to the currents in the two lower wires and use $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$ to find the magnitude of the resultant field due to these currents. (*b*) Note that the forces on the upper wire are away from and directed along the lines to the lower wire and that their horizontal components cancel. We can use the expression for the magnetic force on a current-carrying wire to find the force per unit length on the upper wire.

(*a*) Noting, from the geometry of the wires, that the magnetic field vectors both are at an angle of 30° with the horizontal and that their *x* components cancel, express the resultant magnetic field:

$$\vec{B} = -2\left(\frac{\mu_0}{4\pi}\frac{2I}{R}\sin 30°\right)\hat{j}$$

Substitute numerical values and evaluate B:

$$\vec{B} = -2\left[\left(10^{-7}\ \text{T}\cdot\text{m/A}\right)\frac{2(15\ \text{A})}{0.10\ \text{m}}\sin 30°\right]\hat{j}$$

$$= \boxed{-(30\ \mu\text{T})\,\hat{j}}$$

That is, the magnitude of the magnetic field is 30 μT and its direction is down the page.

(*b*) Express the force per unit length each of the lower wires exerts on the upper wire:

$$\vec{F} = I\left(\vec{\ell}\times\vec{B}\right) = I\left(\ell\hat{k}\times -B\hat{j}\right) = I\ell B\sin 90°\,\hat{i}$$

and

$$\frac{\vec{F}}{\ell} = IB\sin 90°\,\hat{i}$$

Substitute numerical values and evaluate $\frac{\vec{F}}{\ell}$:

$$\frac{\vec{F}}{\ell} = (15\ \text{A})(30\ \mu\text{T})\hat{i}$$

$$= \boxed{\left(4.5\times10^{-4}\ \text{N/m}\right)\hat{i}}$$

That is, the magnitude of the force per unit length on the upper wire is 4.5×10^{-4} N/m and the direction of this force is to the right.

36 •• An infinitely long wire lies along the x axis, and carries current I in the $+x$ direction. A second infinitely long wire lies along the y axis, and carries current I in the $+y$ direction. At what points in the $z = 0$ plane is the resultant magnetic field zero?

Picture the Problem Let the numeral 1 denote the current flowing in the $+x$ direction and the magnetic field resulting from it and the numeral 2 denote the current flowing in the $+y$ direction and the magnetic field resulting from it. We can express the magnetic field anywhere in the xy plane using $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$ and the right-hand rule and then impose the condition that $\vec{B} = 0$ to determine the set of points that satisfy this condition.

Express the resultant magnetic field due to the two current-carrying wires:

$$\vec{B} = \vec{B}_1 + \vec{B}_2 \qquad (1)$$

Express the magnetic field due to the current flowing in the $+x$ direction:

$$\vec{B}_1 = \frac{\mu_0}{4\pi}\frac{2I_1}{y}\hat{k}$$

Express the magnetic field due to the current flowing in the +y direction:

$$\vec{B}_2 = -\frac{\mu_0}{4\pi}\frac{2I_2}{x}\hat{k}$$

Substitute for $\vec{B}_1$ and $\vec{B}_2$ in equation (1) and simplify to obtain:

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{2I}{y}\hat{k} - \frac{\mu_0}{4\pi}\frac{2I}{x}\hat{k} = \left(\frac{\mu_0}{4\pi}\frac{2I}{y} - \frac{\mu_0}{4\pi}\frac{2I}{x}\right)\hat{k}$$

because $I = I_1 = I_2$.

For $\vec{B} = 0$:

$$\frac{\mu_0}{4\pi}\frac{2I}{y} - \frac{\mu_0}{4\pi}\frac{2I}{x} = 0 \Rightarrow x = y.$$

$\vec{B} = 0$ everywhere on the plane that contains both the z axis and the line $y = x$ in the $z = 0$ plane.

37 •• [SSM] An infinitely long wire lies along the z axis and carries a current of 20 A in the +z direction. A second infinitely long wire that is parallel to the z and intersects the x axis at x = 10.0 cm. (a) Find the current in the second wire if the magnetic field is zero at (2.0 cm, 0, 0) is zero. (b) What is the magnetic field at (5.0 cm, 0, 0)?

Picture the Problem Let the numeral 1 denote the current flowing along the positive z axis and the magnetic field resulting from it and the numeral 2 denote the current flowing in the wire located at x = 10 cm and the magnetic field resulting from it. We can express the magnetic field anywhere in the xy plane using $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$ and the right-hand rule and then impose the condition that $\vec{B} = 0$ to determine the current that satisfies this condition.

(a) Express the resultant magnetic field due to the two current-carrying wires:

$$\vec{B} = \vec{B}_1 + \vec{B}_2 \qquad (1)$$

Express the magnetic field at x = 2.0 cm due to the current flowing in the +z direction:

$$\vec{B}_1(2.0\,\text{cm}) = \frac{\mu_0}{4\pi}\left(\frac{2I_1}{2.0\,\text{cm}}\right)\hat{j}$$

Express the magnetic field at x = 2.0 cm due to the current flowing in the wire at x = 10.0 cm:

$$\vec{B}_2(2.0\,\text{cm}) = -\frac{\mu_0}{4\pi}\left(\frac{2I_2}{8.0\,\text{cm}}\right)\hat{j}$$

Substitute for $\vec{B}_1$ and $\vec{B}_2$ in equation (1) and simplify to obtain:

$$\vec{B} = \frac{\mu_0}{4\pi}\left(\frac{2I_1}{2.0\,\text{cm}}\right)\hat{j} - \frac{\mu_0}{4\pi}\left(\frac{2I_2}{8.0\,\text{cm}}\right)\hat{j} = \left(\frac{\mu_0}{4\pi}\frac{2I_1}{2.0\,\text{cm}} - \frac{\mu_0}{4\pi}\frac{2I_2}{8.0\,\text{cm}}\right)\hat{j}$$

For $\vec{B} = 0$:

$$\frac{\mu_0}{4\pi}\left(\frac{2I_1}{2.0\,\text{cm}}\right) - \frac{\mu_0}{4\pi}\left(\frac{2I_2}{8.0\,\text{cm}}\right) = 0$$

or

$$\frac{I_1}{2.0} - \frac{I_2}{8.0} = 0 \Rightarrow I_2 = 4I_1$$

Substitute numerical values and evaluate I_2:

$$I_2 = 4(20\,\text{A}) = \boxed{80\,\text{A}}$$

(b) Express the magnetic field at $x = 5.0$ cm:

$$\vec{B}(5.0\,\text{cm}) = \frac{\mu_0}{4\pi}\left(\frac{2I_1}{5.0\,\text{cm}}\right)\hat{j} - \frac{\mu_0}{4\pi}\left(\frac{2I_2}{5.0\,\text{cm}}\right)\hat{j} = \frac{2\mu_0}{4\pi(5.0\,\text{cm})}(I_1 - I_2)\hat{j}$$

Substitute numerical values and evaluate $\vec{B}(5.0\,\text{cm})$:

$$\vec{B}(5.0\,\text{cm}) = \frac{2(10^{-7}\,\text{T}\cdot\text{m/A})}{5.0\,\text{cm}}(20\,\text{A} - 80\,\text{A})\hat{j} = \boxed{-(0.24\,\text{mT})\hat{j}}$$

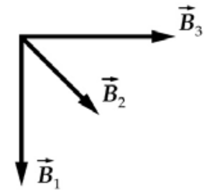
38 •• Three long parallel wires are at the corners of a square, as shown in Figure 27- 54. The wires each carry a current I. Find the magnetic field at the unoccupied corner of the square when (a) all the currents are into the page, (b) I_1 and I_3 are into the page and I_2 is out, and (c) I_1 and I_2 are into the page and I_3 is out. Your answers should be in terms of I and L.

Picture the Problem Choose a coordinate system with its origin at the lower left-hand corner of the square, the +x axis to the right and the +y axis upward. We can use $B = \frac{\mu_0}{4\pi}\frac{2I}{R}$ and the right-hand rule to find the magnitude and direction of the magnetic field at the unoccupied corner due to each of the currents, and superimpose these fields to find the resultant field.

(a) Express the resultant magnetic field at the unoccupied corner:

$$\vec{B} = \vec{B}_1 + \vec{B}_2 + \vec{B}_3 \qquad (1)$$

When all the currents are into the paper their magnetic fields at the unoccupied corner are as shown to the right:



Express the magnetic field at the unoccupied corner due to the current I_1:

$$\vec{B}_1 = -\frac{\mu_0}{4\pi}\frac{2I}{L}\hat{j}$$

Express the magnetic field at the unoccupied corner due to the current I_2:

$$\vec{B}_2 = \frac{\mu_0}{4\pi}\frac{2I}{L\sqrt{2}}\cos 45°\left(\hat{i}-\hat{j}\right) = \frac{\mu_0}{4\pi}\frac{2I}{2L}\left(\hat{i}-\hat{j}\right)$$

Express the magnetic field at the unoccupied corner due to the current I_3:

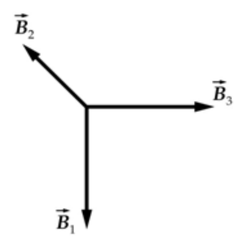
$$\vec{B}_3 = \frac{\mu_0}{4\pi}\frac{2I}{L}\hat{i}$$

Substitute in equation (1) and simplify to obtain:

$$\vec{B} = -\frac{\mu_0}{4\pi}\frac{2I}{L}\hat{j} + \frac{\mu_0}{4\pi}\frac{2I}{2L}\left(\hat{i}-\hat{j}\right) + \frac{\mu_0}{4\pi}\frac{2I}{L}\hat{i} = \frac{\mu_0}{4\pi}\frac{2I}{L}\left(-\hat{j}+\frac{1}{2}\left(\hat{i}-\hat{j}\right)+\hat{i}\right)$$

$$= \frac{\mu_0}{4\pi}\frac{2I}{L}\left[\left(1+\frac{1}{2}\right)\hat{i}+\left(-1-\frac{1}{2}\right)\hat{j}\right] = \boxed{\frac{3\mu_0 I}{4\pi L}\left[\hat{i}-\hat{j}\right]}$$

(*b*) When I_2 is out of the paper the magnetic fields at the unoccupied corner are as shown to the right:



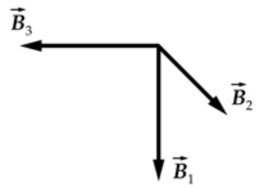
Express the magnetic field at the unoccupied corner due to the current I_2:

$$\vec{B}_2 = \frac{\mu_0}{4\pi}\frac{2I}{L\sqrt{2}}\cos 45°\left(-\hat{i}+\hat{j}\right) = \frac{\mu_0}{4\pi}\frac{2I}{2L}\left(-\hat{i}+\hat{j}\right)$$

Substitute in equation (1) and simplify to obtain:

$$\vec{B} = -\frac{\mu_0}{4\pi}\frac{2I}{L}\hat{j} + \frac{\mu_0}{4\pi}\frac{2I}{2L}\left(-\hat{i}+\hat{j}\right) + \frac{\mu_0}{4\pi}\frac{2I}{L}\hat{i} = \frac{\mu_0}{4\pi}\frac{2I}{L}\left(-\hat{j}+\frac{1}{2}\left(-\hat{i}+\hat{j}\right)+\hat{i}\right)$$
$$= \frac{\mu_0}{4\pi}\frac{2I}{L}\left[\left(1-\frac{1}{2}\right)\hat{i}+\left(-1+\frac{1}{2}\right)\hat{j}\right] = \frac{\mu_0}{4\pi}\frac{2I}{L}\left[\frac{1}{2}\hat{i}-\frac{1}{2}\hat{j}\right] = \boxed{\frac{\mu_0 I}{4\pi L}\left[\hat{i}-\hat{j}\right]}$$

(*c*) When I_1 and I_2 are in and I_3 is out of the paper the magnetic fields at the unoccupied corner are as shown to the right:



From (*a*) or (*b*) we have:

$$\vec{B}_1 = -\frac{\mu_0}{4\pi}\frac{2I}{L}\hat{j}$$

From (*a*) we have:

$$\vec{B}_2 = \frac{\mu_0}{4\pi}\frac{2I}{L\sqrt{2}}\cos 45°\left(\hat{i}-\hat{j}\right)$$
$$= \frac{\mu_0}{4\pi}\frac{2I}{2L}\left(\hat{i}-\hat{j}\right)$$

Express the magnetic field at the unoccupied corner due to the current I_3:

$$\vec{B}_3 = -\frac{\mu_0}{4\pi}\frac{2I}{L}\hat{i}$$

Substitute in equation (1) and simplify to obtain:

$$\vec{B} = -\frac{\mu_0}{4\pi}\frac{2I}{L}\hat{j} + \frac{\mu_0}{4\pi}\frac{2I}{2L}\left(\hat{i}-\hat{j}\right) - \frac{\mu_0}{4\pi}\frac{2I}{L}\hat{i} = \frac{\mu_0}{4\pi}\frac{2I}{L}\left(-\hat{j}+\frac{1}{2}\left(\hat{i}-\hat{j}\right)-\hat{i}\right)$$
$$= \frac{\mu_0}{4\pi}\frac{2I}{L}\left[\left(-1+\frac{1}{2}\right)\hat{i}+\left(-1-\frac{1}{2}\right)\hat{j}\right] = \boxed{\frac{\mu_0 I}{4\pi L}\left[-\hat{i}-3\hat{j}\right]}$$

39 •• [SSM] Four long, straight parallel wires each carry current *I*. In a plane perpendicular to the wires, the wires are at the corners of a square of side length *a*. Find the magnitude of the force per unit length on one of the wires if (*a*) all the currents are in the same direction and (*b*) the currents in the wires at adjacent corners are oppositely directed.

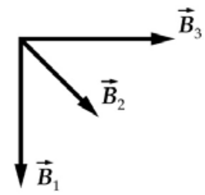
Picture the Problem Choose a coordinate system with its origin at the lower left-hand corner of the square, the +*x* axis to the right and the +*y* axis upward. Let the numeral 1 denote the wire and current in the upper left-hand corner of the

square, the numeral 2 the wire and current in the lower left-hand corner (at the origin) of the square, and the numeral 3 the wire and current in the lower right-hand corner of the square. We can use $B=\frac{\mu_0}{4\pi}\frac{2I}{R}$ and the right-hand rule to find the magnitude and direction of the magnetic field at, say, the upper right-hand corner due to each of the currents, superimpose these fields to find the resultant field, and then use $F = I\ell B$ to find the force per unit length on the wire.

(*a*) Express the resultant magnetic field at the upper right-hand corner:

$$\vec{B} = \vec{B}_1 + \vec{B}_2 + \vec{B}_3 \quad (1)$$

When all the currents are into the paper their magnetic fields at the upper right-hand corner are as shown to the right:



Express the magnetic field due to the current I_1:

$$\vec{B}_1 = -\frac{\mu_0}{4\pi}\frac{2I}{a}\hat{j}$$

Express the magnetic field due to the current I_2:

$$\vec{B}_2 = \frac{\mu_0}{4\pi}\frac{2I}{a\sqrt{2}}\cos 45°\left(\hat{i}-\hat{j}\right) = \frac{\mu_0}{4\pi}\frac{2I}{2a}\left(\hat{i}-\hat{j}\right)$$

Express the magnetic field due to the current I_3:

$$\vec{B}_3 = \frac{\mu_0}{4\pi}\frac{2I}{a}\hat{i}$$

Substitute in equation (1) and simplify to obtain:

$$\vec{B} = -\frac{\mu_0}{4\pi}\frac{2I}{a}\hat{j} + \frac{\mu_0}{4\pi}\frac{2I}{2a}\left(\hat{i}-\hat{j}\right) + \frac{\mu_0}{4\pi}\frac{2I}{a}\hat{i} = \frac{\mu_0}{4\pi}\frac{2I}{a}\left(-\hat{j}+\frac{1}{2}\left(\hat{i}-\hat{j}\right)+\hat{i}\right)$$
$$= \frac{\mu_0}{4\pi}\frac{2I}{a}\left[\left(1+\frac{1}{2}\right)\hat{i}+\left(-1-\frac{1}{2}\right)\hat{j}\right] = \frac{3\mu_0 I}{4\pi a}\left[\hat{i}-\hat{j}\right]$$

Using the expression for the magnetic force on a current-carrying wire, express the force per unit length on the wire at the upper right-hand corner:

$$\frac{F}{\ell} = BI \quad (2)$$

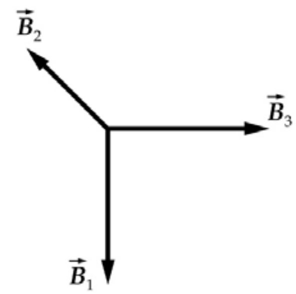
Substitute to obtain:

$$\frac{\vec{F}}{\ell}=\frac{3\mu_0 I^2}{4\pi a}\left[\hat{i}-\hat{j}\right]$$

and

$$\frac{F}{\ell}=\sqrt{\left(\frac{3\mu_0 I^2}{4\pi a}\right)^2+\left(\frac{3\mu_0 I^2}{4\pi a}\right)^2}=\boxed{\frac{3\sqrt{2}\mu_0 I^2}{4\pi a}}$$

(*b*) When the current in the upper right-hand corner of the square is out of the page, and the currents in the wires at adjacent corners are oppositely directed, the magnetic fields at the upper right-hand are as shown to the right:



Express the magnetic field at the upper right-hand corner due to the current I_2:

$$\vec{B}_2=\frac{\mu_0}{4\pi}\frac{2I}{a\sqrt{2}}\cos 45°\left(-\hat{i}+\hat{j}\right)=\frac{\mu_0}{4\pi}\frac{2I}{2a}\left(-\hat{i}+\hat{j}\right)$$

Using $\vec{B}_1$ and $\vec{B}_3$ from (*a*), substitute in equation (1) and simplify to obtain:

$$\vec{B}=-\frac{\mu_0}{4\pi}\frac{2I}{a}\hat{j}+\frac{\mu_0}{4\pi}\frac{2I}{2a}\left(-\hat{i}+\hat{j}\right)+\frac{\mu_0}{4\pi}\frac{2I}{a}\hat{i}=\frac{\mu_0}{4\pi}\frac{2I}{a}\left(-\hat{j}+\frac{1}{2}\left(-\hat{i}+\hat{j}\right)+\hat{i}\right)$$

$$=\frac{\mu_0}{4\pi}\frac{2I}{a}\left[\left(1-\frac{1}{2}\right)\hat{i}+\left(-1+\frac{1}{2}\right)\hat{j}\right]=\frac{\mu_0}{4\pi}\frac{2I}{a}\left[\frac{1}{2}\hat{i}-\frac{1}{2}\hat{j}\right]=\frac{\mu_0 I}{4\pi a}\left[\hat{i}-\hat{j}\right]$$

Substitute in equation (2) to obtain:

$$\frac{\vec{F}}{\ell}=\frac{\mu_0 I^2}{4\pi a}\left[\hat{i}-\hat{j}\right]$$

and

$$\frac{F}{\ell}=\sqrt{\left(\frac{\mu_0 I^2}{4\pi a}\right)^2+\left(\frac{\mu_0 I^2}{4\pi a}\right)^2}=\boxed{\frac{\sqrt{2}\mu_0 I^2}{4\pi a}}$$

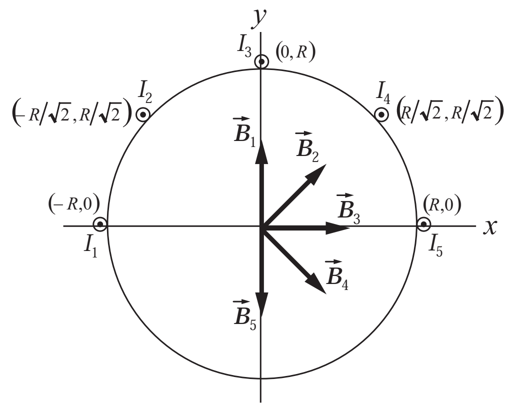
40 •• Five long straight current-carrying wires are parallel to the *z* axis, and each carries a current *I* in the +*z* direction. The wires each are a distance *R* from the *z* axis. Two of the wires intersect the *x* axis, one at $x = R$ and the other at $x = –R$. Another wire intersects the *y* axis at $y = R$. One of the remaining wires intersects the $z = 0$ plane at the point $\left(R/\sqrt{2}, R/\sqrt{2}\right)$ and the last remaining wire

intersects the $z = 0$ plane at the point $\left(-R/\sqrt{2}, R/\sqrt{2}\right)$. Find the magnetic field on the z axis.

Picture the Problem The configuration is shown in the adjacent figure. Here the $+z$ axis is out of the plane of the paper, the $+x$ axis is to the right, and the $+y$ axis is upward. We can use

$$B = \frac{\mu_0}{4\pi}\frac{2I}{R}$$

and the right-hand rule to find the magnetic field due to the current in each wire and add these magnetic fields vectorially to find the resultant field.



Express the resultant magnetic field on the z axis:

$$\vec{B} = \vec{B}_1 + \vec{B}_2 + \vec{B}_3 + \vec{B}_4 + \vec{B}_5 \quad (1)$$

$\vec{B}_1$ is given by: $\vec{B}_1 = B\hat{j}$

$\vec{B}_2$ is given by: $\vec{B}_2 = (B\cos 45°)\hat{i} + (B\sin 45°)\hat{j}$

$\vec{B}_3$ is given by: $\vec{B}_3 = B\hat{i}$

$\vec{B}_4$ is given by: $\vec{B}_4 = (B\cos 45°)\hat{i} - (B\sin 45°)\hat{j}$

$\vec{B}_5$ is given by: $\vec{B}_5 = -B\hat{j}$

Substitute for $\vec{B}_1$, $\vec{B}_2$, $\vec{B}_3$, $\vec{B}_4$, and $\vec{B}_5$ in equation (1) and simplify to obtain:

$$\begin{aligned}\vec{B} &= B\hat{j} + (B\cos 45°)\hat{i} + (B\sin 45°)\hat{j} + B\hat{i} + (B\cos 45°)\hat{i} - (B\sin 45°)\hat{j} - B\hat{j} \\ &= (B\cos 45°)\hat{i} + B\hat{i} + (B\cos 45°)\hat{i} = (B + 2B\cos 45°)\hat{i} = \left(1+\sqrt{2}\right)B\hat{i}\end{aligned}$$

Express B due to each current at $z = 0$:

$$B = \frac{\mu_0}{4\pi}\frac{2I}{R}$$

Substitute for B to obtain:

$$\vec{B} = \boxed{\left(1+\sqrt{2}\right)\frac{\mu_0 I}{2\pi R}\,\hat{i}}$$

Magnetic Field Due to a Current-carrying Solenoid

41 •• **[SSM]** A solenoid that has length 30 cm, radius 1.2 cm, and 300 turns carries a current of 2.6 A. Find the magnitude of the magnetic field on the axis of the solenoid (*a*) at the center of the solenoid, (*b*) at one end of the solenoid.

Picture the Problem We can use $B_x = \frac{1}{2}\mu_0 nI\left(\frac{b}{\sqrt{b^2+R^2}} + \frac{a}{\sqrt{a^2+R^2}}\right)$ to find B at any point on the axis of the solenoid. Note that the number of turns per unit length for this solenoid is 300 turns/0.30 m = 1000 turns/m.

Express the magnetic field at any point on the axis of the solenoid:

$$B_x = \frac{1}{2}\mu_0 nI\left(\frac{b}{\sqrt{b^2+R^2}} + \frac{a}{\sqrt{a^2+R^2}}\right)$$

Substitute numerical values to obtain:

$$B_x = \frac{1}{2}\left(4\pi\times10^{-7}\ \text{T}\cdot\text{m/A}\right)(1000)(2.6\ \text{A})\left(\frac{b}{\sqrt{b^2+(0.012\,\text{m})^2}} + \frac{a}{\sqrt{a^2+(0.012\,\text{m})^2}}\right)$$
$$= (1.634\,\text{mT})\left(\frac{b}{\sqrt{b^2+(0.012\,\text{m})^2}} + \frac{a}{\sqrt{a^2+(0.012\,\text{m})^2}}\right)$$

(*a*) Evaluate B_x for $a = b = 0.15$ m:

$$B_x(0.15\,\text{m}) = (1.634\,\text{mT})\left(\frac{0.15\,\text{m}}{\sqrt{(0.15\,\text{m})^2+(0.012\,\text{m})^2}} + \frac{0.15\,\text{m}}{\sqrt{(0.15\,\text{m})^2+(0.012\,\text{m})^2}}\right)$$
$$= \boxed{3.3\,\text{mT}}$$

(*b*) Evaluate B_x (= B_{end}) for $a = 0$ and $b = 0.30$ m:

$$B_x(0.30\,\text{m}) = (1.634\,\text{mT})\left(\frac{0.30\,\text{m}}{\sqrt{(0.30\,\text{m})^2+(0.012\,\text{m})^2}}\right) = \boxed{1.6\,\text{mT}}$$

Note that $B_{\text{end}} \approx \frac{1}{2}B_{\text{center}}$.

42 • A solenoid is 2.7-m long, has a radius of 0.85 cm, and has 600 turns. It carries a current I of 2.5 A. What is the magnitude of the magnetic field B inside the solenoid and far from either end?

Picture the Problem We can use $B = \mu_0 nI$ to find the magnetic field inside the solenoid and far from either end.

The magnetic field inside the solenoid and far from either end is given by:

$$B = \mu_0 nI$$

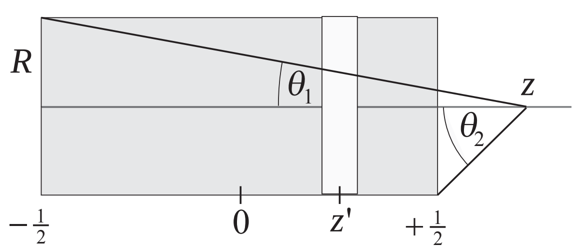
Substitute numerical values and evaluate B:

$$B = \left(4\pi \times 10^{-7}\ \text{N/A}^2\right)\left(\frac{600}{2.7\,\text{m}}\right)(2.5\,\text{A})$$

$$= \boxed{0.70\,\text{mT}}$$

43 •• A solenoid has n turns per unit length, has a radius R, and carries a current I. Its axis coincides with the z axis with one end at $z = -\frac{1}{2}\ell$ and the other end at $z = +\frac{1}{2}\ell$. Show that the magnitude of the magnetic field at a point on the z axis in the interval $z > \frac{1}{2}\ell$ is given by $B = \frac{1}{2}\mu_0 nI(\cos\theta_1 - \cos\theta_2)$, where the angles are related to the geometry by: $\cos\theta_1 = \left(z + \frac{1}{2}\ell\right)\Big/\sqrt{\left(z + \frac{1}{2}\ell\right)^2 + R^2}$ and $\cos\theta_2 = \left(z - \frac{1}{2}\ell\right)\Big/\sqrt{\left(z - \frac{1}{2}\ell\right)^2 + R^2}$.

Picture the Problem The solenoid, extending from $z = -\ell/2$ to $z = \ell/2$, with the origin at its center, is shown in the following diagram. To find the field at the point whose coordinate is z outside the solenoid we can determine the field at z due to an infinitesimal segment of the solenoid of width dz' at z', and then integrate from $z = -\ell/2$ to $z = \ell/2$. We'll treat the segment as a coil of thickness ndz' carrying a current I.



Express the field dB at the axial point whose coordinate is z:

$$dB = \frac{\mu_0}{4\pi}\frac{2\pi R^2 I}{\left[(z - z')^2 + R^2\right]^{3/2}}dz'$$

Integrate dB from $z=-\ell/2$ to $z=\ell/2$ to obtain:

$$B=\frac{\mu_0 nIR^2}{2}\int_{-\ell/2}^{\ell/2}\frac{dz'}{\left[(z-z')^2+R^2\right]^{3/2}}=\frac{\mu_0 nI}{2}\left(\frac{z+\ell/2}{\sqrt{(z+\ell/2)^2+R^2}}-\frac{z-\ell/2}{\sqrt{(z-\ell/2)^2+R^2}}\right)$$

Refer to the diagram to express $\cos\theta_1$ and $\cos\theta_2$:

$$\cos\theta_1=\frac{z+\frac{1}{2}\ell}{\left[R^2+\left(z+\frac{1}{2}\ell\right)^2\right]^{1/2}}$$

and

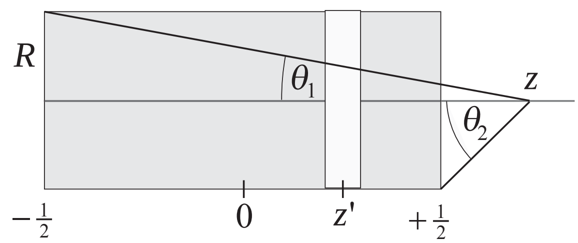
$$\cos\theta_2=\frac{z-\frac{1}{2}\ell}{\left[R^2+\left(z-\frac{1}{2}\ell\right)^2\right]^{1/2}}$$

Substitute for the terms in parentheses in the expression for B to obtain:

$$B=\boxed{\tfrac{1}{2}\mu_0 nI\left(\cos\theta_1-\cos\theta_2\right)}$$

44 ••• In Problem 43, an expression for the magnitude of the magnetic field along the axis of a solenoid is given. For $z \gg \ell$ and $\ell \gg R$, the angles θ_1 and θ_2 are very small, so the small-angle approximations $\cos\theta\approx 1-\frac{1}{2}\theta^2$ and $\sin\theta\approx\tan\theta\approx\theta$ are highly accurate. (*a*) Draw a diagram and use it to show that, for these conditions, the angles can be approximated as $\theta_1\approx R/\left(z+\frac{1}{2}\ell\right)$ and $\theta_2\approx R/\left(z-\frac{1}{2}\ell\right)$. (*b*) Using these approximations, show that the magnetic field at a points on the z axis where $z \gg \ell$ can be written as $B=\dfrac{\mu_0}{4\pi}\left(\dfrac{q_n}{r_2^2}-\dfrac{q_n}{r_1^2}\right)$ where $r_2=z-\frac{1}{2}\ell$ is the distance to the near end of the solenoid, $r_1=z+\frac{1}{2}\ell$ is the distance to the far end, and the quantity q_m is defined by $q_m=nI\pi R^2=\mu/\ell$, where $\mu=NI\pi R^2$ is the magnitude of the magnetic moment of the solenoid.

Picture the Problem (*a*) We can use the results of Problem 43, together with the small angle approximation for the cosine and tangent functions, to show that θ_1 and θ_2 are as given in the problem statement and that (*b*) $B=\dfrac{\mu_0}{4\pi}\left(\dfrac{q_m}{r_2^2}-\dfrac{q_m}{r_1^2}\right)$. The angles θ_1 and θ_2 are shown in the diagram. Note that $\tan\theta_1=R/\left(z+\ell/2\right)$ and $\tan\theta_2=R/\left(z-\ell/2\right)$.



(*a*) Apply the small angle approximation $\tan\theta \approx \theta$ to obtain:

$$\theta_1 \approx \boxed{\frac{R}{z+\frac{1}{2}\ell}} \text{ and } \theta_2 \approx \boxed{\frac{R}{z-\frac{1}{2}\ell}}$$

(*b*) Express the magnetic field outside the solenoid:

$$B = \tfrac{1}{2}\mu_0 nI\left(\cos\theta_1 - \cos\theta_2\right)$$

Apply the small angle approximation for the cosine function to obtain:

$$\cos\theta_1 = 1 - \tfrac{1}{2}\left(\frac{R}{z+\frac{1}{2}\ell}\right)^2$$

and

$$\cos\theta_2 = 1 - \tfrac{1}{2}\left(\frac{R}{z-\frac{1}{2}\ell}\right)^2$$

Substitute and simplify to obtain:

$$B = \tfrac{1}{2}\mu_0 nI\left[1 - \tfrac{1}{2}\left(\frac{R}{z+\frac{1}{2}\ell}\right)^2 - 1 + \tfrac{1}{2}\left(\frac{R}{z-\frac{1}{2}\ell}\right)^2\right] = \tfrac{1}{4}\mu_0 nIR^2\left[\frac{1}{\left(z-\frac{1}{2}\ell\right)^2} - \frac{1}{\left(z+\frac{1}{2}\ell\right)^2}\right]$$

Let $r_1 = z + \frac{1}{2}\ell$ be the distance to the near end of the solenoid, $r_2 = z - \frac{1}{2}\ell$ the distance to the far end, and $q_m = nI\pi R^2 = \mu/\ell$, where $\mu = nI\pi R^2$ is the magnetic moment of the solenoid to obtain:

$$B = \boxed{\frac{\mu_0}{4\pi}\left(\frac{q_\mathrm{m}}{r_2^2} - \frac{q_\mathrm{m}}{r_1^2}\right)}$$

Using Ampère's Law

45 • **[SSM]** A long, straight, thin-walled cylindrical shell of radius *R* carries a current *I* parallel to the central axis of the shell. Find the magnetic field (including direction) both inside and outside the shell.

Picture the Problem We can apply Ampère's law to a circle centered on the axis of the cylinder and evaluate this expression for $r < R$ and $r > R$ to find B inside and outside the cylinder. We can use the right-hand rule to determine the direction of the magnetic fields.

Apply Ampère's law to a circle centered on the axis of the cylinder:

$$\oint_C \vec{B} \cdot d\vec{\ell} = \mu_0 I_C$$

Note that, by symmetry, the field is the same everywhere on this circle.

Evaluate this expression for $r < R$:

$$\oint_C \vec{B}_{\text{inside}} \cdot d\vec{\ell} = \mu_0(0) = 0$$

Solve for B_{inside} to obtain:

$$B_{\text{inside}} = \boxed{0}$$

Evaluate this expression for $r > R$:

$$\oint_C \vec{B}_{\text{outside}} \cdot d\vec{\ell} = B(2\pi R) = \mu_0 I$$

Solve for B_{outside} to obtain:

$$B_{\text{outside}} = \boxed{\frac{\mu_0 I}{2\pi R}}$$

The direction of the magnetic field is in the direction of the curled fingers of your right hand when you grab the cylinder with your right thumb in the direction of the current.

46 • In Figure 27-55, one current is 8.0 A into the page, the other current is 8.0 A out of the page, and each curve is a circular path. (*a*) Find $\oint_C \vec{\boldsymbol{B}} \cdot d\vec{\boldsymbol{\ell}}$ for each path, assuming that each integral is to be evaluated in the counterclockwise direction. (*b*) Which path, if any, can be used to find the combined magnetic field of these currents?

Picture the Problem We can use Ampère's law, $\oint_C \vec{B} \cdot d\vec{\ell} = \mu_0 I_C$, to find the line integral $\oint_C \vec{B} \cdot d\vec{\ell}$ for each of the three paths.

(*a*) Noting that the angle between $\vec{B}$ and $d\vec{\ell}$ is 180°, evaluate $\oint_C \vec{B}\cdot d\vec{\ell}$ for C_1:

$$\oint_{C_1} \vec{B}\cdot d\vec{\ell} = \boxed{-\mu_0(8.0\,\mathrm{A})}$$

The positive tangential direction on C_1 is counterclockwise. Therefore, in accord with convention (a right-hand rule), the positive normal direction for the flat surface bounded by C_1 is out of the page. $\oint_C \vec{B}\cdot d\vec{\ell}$ is negative because the current through the surface is in the negative direction (into the page).

Noting that the net current bounded by C_2 is zero, evaluate $\oint_C \vec{B}\cdot d\vec{\ell}$:

$$\oint_{C_2} \vec{B}\cdot d\vec{\ell} = \mu_0(8.0\,\mathrm{A} - 8.0\,\mathrm{A}) = \boxed{0}$$

Noting that the angle between $\vec{B}$ and $d\vec{\ell}$ is 0°, Evaluate $\oint_C \vec{B}\cdot d\vec{\ell}$ for C_3:

$$\oint_{C_3} \vec{B}\cdot d\vec{\ell} = \boxed{+\mu_0(8.0\,\mathrm{A})}$$

(*b*) None of the paths can be used to find $\vec{B}$ because the current configuration does not have cylindrical symmetry, which means that $\vec{B}$ cannot be factored out of the integral.

47 •• [SSM] Show that a uniform magnetic field that has no fringing field, such as that shown in Figure 27- 56 is impossible because it violates Ampère's law. Do this calculation by applying Ampère's law to the rectangular curve shown by the dashed lines.

Determine the Concept The contour integral consists of four portions, two horizontal portions for which $\oint_C \vec{B}\cdot d\vec{\ell} = 0$, and two vertical portions. The portion within the magnetic field gives a nonvanishing contribution, whereas the portion outside the field gives no contribution to the contour integral. Hence, the contour integral has a finite value. However, it encloses no current; thus, it appears that Ampère's law is violated. What this demonstrates is that there must be a fringing field so that the contour integral does vanish.

48 •• A coaxial cable consists of a solid conducting cylinder that has a radius equal to 1.00 mm and a conducting cylindrical shell that has an inner radius equal to 2.00 mm and an outer radius equal to 3.00 mm. The solid cylinder carries a current of 15.0 A parallel to the central axis. The cylindrical shell carries and current of 15.0 A in the opposite direction. Assume that the current densities are uniformly distributed in both conductors. (*a*) Using a **spreadsheet** program or graphing calculator, graph the magnitude of the magnetic field as a function of the

radial distance r from the central axis for $0 < R < 3.00$ mm. (*b*) What is the magnitude of the field for $R > 3.00$ mm?

Picture the Problem Let r_1 = 1.00 mm, r_2 = 2.00 mm, and r_3 = 3.00 mm and apply Ampère's law in each of the three regions to obtain expressions for B in each part of the coaxial cable and outside the coaxial cable.

(*a*) Apply Ampère's law to a circular path of radius $r < r_1$ to obtain:

$$B_{r<r_1}(2\pi r) = \mu_0 I_C$$

Because the current is uniformly distributed over the cross section of the inner wire:

$$\frac{I_C}{\pi r^2} = \frac{I}{\pi r_1^2} \Rightarrow I_C = \frac{r^2}{r_1^2} I$$

Substitute for I_C to obtain:

$$B_{r<r_1}(2\pi r) = \mu_0 \frac{r^2}{r_1^2} I$$

Solving for $B_{r<r_1}$ yields:

$$B_{r<r_1} = \frac{2\mu_0 I}{4\pi} \frac{r}{r_1^2} \qquad (1)$$

Apply Ampère's law to a circular path of radius $r_1 < r < r_2$ to obtain:

$$B_{r_1<r<r_2}(2\pi r) = \mu_0 I$$

Solving for $B_{r_1<r<r_2}$ yields:

$$B_{r_1<r<r_2} = \frac{2\mu_0 I}{4\pi} \frac{1}{r} \qquad (2)$$

Apply Ampère's law to a circular path of radius $r_2 < r < r_3$ to obtain:

$$B_{r_2<r<r_3}(2\pi r) = \mu_0 I_C = \mu_0 (I - I')$$

where I' is the current in the outer conductor at a distance less than r from the center of the inner conductor.

Because the current is uniformly distributed over the cross section of the outer conductor:

$$\frac{I'}{\pi r^2 - \pi r_2^2} = \frac{I}{\pi r_3^2 - \pi r_2^2}$$

Solving for I' yields:

$$I' = \frac{r^2 - r_2^2}{r_3^2 - r_2^2} I$$

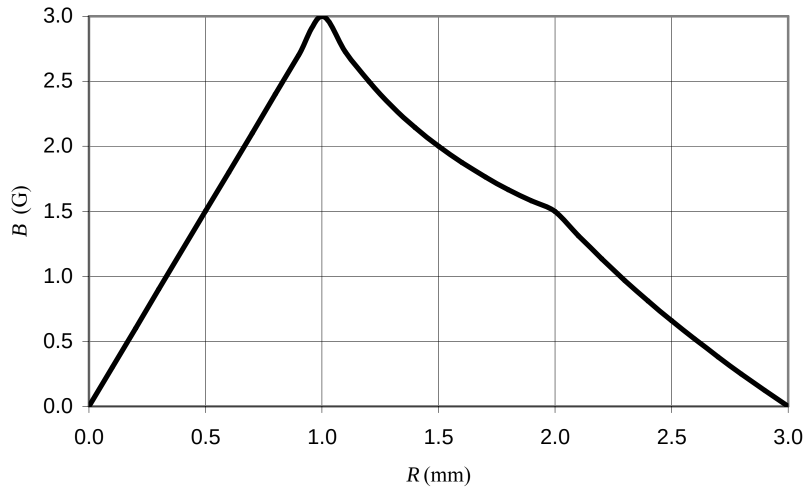
Substitute for I' to obtain:

$$B_{r_2<r<r_3}(2\pi r) = \mu_0 \left(I - \frac{r^2 - r_2^2}{r_3^2 - r_2^2} I \right)$$

Solving for $B_{r_1<r<r_2}$ yields:

$$B_{r_2<r<r_3} = \frac{2\mu_0 I}{4\pi r}\left(1-\frac{r^2-r_2^2}{r_3^2-r_2^2}\right) \qquad (3)$$

A spreadsheet program was used to plot the following graph of equations (1), (2), and (3).



(*b*) Apply Ampère's law to a circular path of radius $r > r_3$ to obtain:

$$B_{r>r_3}(2\pi r) = \mu_0 I_C = \mu_0(I - I) = 0$$

and $B_{r>r_3} = \boxed{0}$

49 •• **[SSM]** A long cylindrical shell has an inner radius a and an outer radius b and carries a current I parallel to the central axis. Assume that within the material of the shell the current density is uniformly distributed. Find an expression for the magnitude of the magnetic field for (*a*) $0 < R < a$, (*b*) $a < R < b$, and (*c*) $R > b$.

Picture the Problem We can use Ampère's law to calculate B because of the high degree of symmetry. The current through C depends on whether R is less than the inner radius a, greater than the inner radius a but less than the outer radius b, or greater than the outer radius b.

(*a*) Apply Ampère's law to a circular path of radius $R < a$ to obtain:

$$\oint_C \vec{B}_{r<a} \cdot d\vec{\ell} = \mu_0 I_C = \mu_0(0) = 0$$

and $B_{r<a} = \boxed{0}$

(*b*) Use the uniformity of the current over the cross-section of the conductor to express the current I' enclosed by a circular path whose radius satisfies the condition $a < R < b$:

$$\frac{I'}{\pi\left(R^2 - a^2\right)} = \frac{I}{\pi\left(b^2 - a^2\right)}$$

Solving for $I_C = I'$ yields:

$$I_C = I' = I\,\frac{R^2 - a^2}{b^2 - a^2}$$

Substitute in Ampère's law to obtain:

$$\oint_C \vec{\boldsymbol{B}}_{a<R<b} \cdot d\vec{\ell} = B_{a<r<b}\left(2\pi R\right)$$
$$= \mu_0 I' = \mu_0 I\,\frac{R^2 - a^2}{b^2 - a^2}$$

Solving for $B_{a<r<b}$ yields:

$$B_{a<r<b} = \boxed{\frac{\mu_0 I}{2\pi r}\,\frac{R^2 - a^2}{b^2 - a^2}}$$

(*c*) Express I_C for $R > b$:

$$I_C = I$$

Substituting in Ampère's law yields:

$$\oint_C \vec{\boldsymbol{B}}_{R>b} \cdot d\vec{\ell} = B_{r>b}\left(2\pi R\right) = \mu_0 I$$

Solve for $B_{R>b}$ to obtain:

$$B_{R>b} = \boxed{\frac{\mu_0 I}{2\pi R}}$$

50 •• Figure 27-57 shows a solenoid that has *n* turns per unit length and carries a current *I*. Apply Ampère's law to the rectangular curve shown in the figure to derive an expression for the magnitude of the magnetic field. Assume that inside the solenoid the magnetic field is uniform and parallel with the central axis, and that outside the solenoid there is no magnetic field.

Picture the Problem The number of turns enclosed within the rectangular area is *na*. Denote the corners of the rectangle, starting in the lower left-hand corner and proceeding counterclockwise, as 1, 2, 3, and 4. We can apply Ampère's law to each side of this rectangle in order to evaluate $\oint_C \vec{\boldsymbol{B}} \cdot d\vec{\ell}$.

Express the integral around the closed path C as the sum of the integrals along the sides of the rectangle:

$$\oint_C \vec{B}\cdot d\vec{\ell} = \int_{1\to 2}\vec{B}\cdot d\vec{\ell} + \int_{2\to 3}\vec{B}\cdot d\vec{\ell} + \int_{3\to 4}\vec{B}\cdot d\vec{\ell} + \int_{4\to 1}\vec{B}\cdot d\vec{\ell}$$

Evaluate $\int_{1\to 2}\vec{B}\cdot d\vec{\ell}$:

$$\int_{1\to 2}\vec{B}\cdot d\vec{\ell} = aB$$

For the paths $2 \to 3$ and $4 \to 1$, $\vec{B}$ is either zero (outside the solenoid) or is perpendicular to $d\vec{\ell}$ and so:

$$\int_{2\to 3}\vec{B}\cdot d\vec{\ell} = \int_{4\to 1}\vec{B}\cdot d\vec{\ell} = 0$$

For the path $3 \to 4$, $\vec{B}$ =0 and:

$$\int_{3\to 4}\vec{B}\cdot d\vec{\ell} = 0$$

Substitute in Ampère's law to obtain:

$$\oint_C \vec{B}\cdot d\vec{\ell} = aB + 0 + 0 + 0 = aB = \mu_0 I_C = \mu_0 naI$$

Solving for B yields:

$$B = \boxed{\mu_0 nI}$$

51 •• [SSM] A tightly wound 1000-turn toroid has an inner radius 1.00 cm and an outer radius 2.00 cm, and carries a current of 1.50 A. The toroid is centered at the origin with the centers of the individual turns in the $z = 0$ plane. In the $z = 0$ plane: (*a*) What is the magnetic field strength at a distance of 1.10 cm from the origin? (*b*) What is the magnetic field strength at a distance of 1.50 cm from the origin?

Picture the Problem The magnetic field inside a tightly wound toroid is given by $B = \mu_0 NI/(2\pi r)$, where $a < r < b$ and a and b are the inner and outer radii of the toroid.

Express the magnetic field of a toroid:

$$B = \frac{\mu_0 NI}{2\pi r}$$

(*a*) Substitute numerical values and evaluate B(1.10 cm):

$$B(1.10\,\text{cm}) = \frac{(4\pi\times 10^{-7}\ \text{N/A}^2)(1000)(1.50\,\text{A})}{2\pi(1.10\,\text{cm})} = \boxed{27.3\,\text{mT}}$$

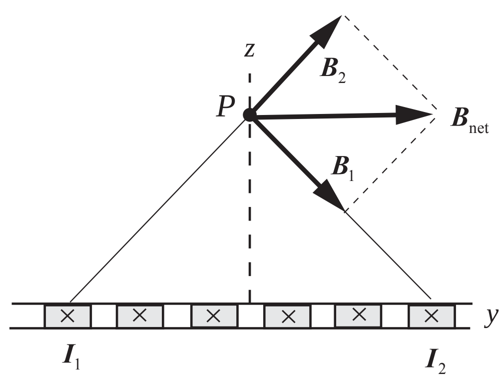
(*b*) Substitute numerical values and evaluate B(1.50 cm):

$$B(1.50\,\text{cm}) = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(1000)(1.50\,\text{A})}{2\pi(1.50\,\text{cm})} = \boxed{20.0\,\text{mT}}$$

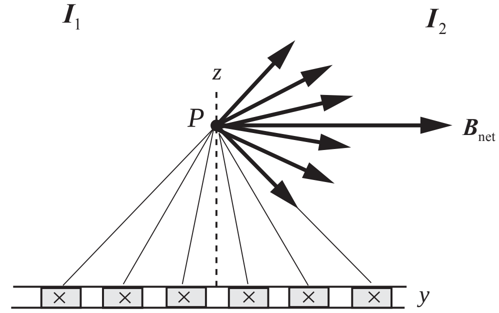
52 ••• A thin conducting sheet in the $z = 0$ plane carries current in the $-x$ direction (Figure 27-88*a*). The sheet extends indefinitely in all directions and the current is uniformly distributed throughout the sheet. To find the direction of the magnetic field at point P consider the field due only to the currents I_1 and I_2 in the two narrow strips shown. The strips are identical, so $I_1 = I_2$. (*a*) What is the direction of the magnetic field at point P due to just I_1 and I_2? Explain your answer using a sketch. (*b*) What is the direction of the magnetic field at point P due to the *entire* sheet? Explain your answer. (*c*) What is the direction of the field at a point to the right of point P (where $y \neq 0$)? Explain your answer. (*d*) What is the direction of the field at a point below the sheet (where $z < 0$)? Explain your answer using a sketch. (*e*) Apply Ampere's law to the rectangular curve (Figure 27-88*b*) to show that the magnetic field strength at point P is given by $B = \frac{1}{2}\mu_0\lambda$, where $\lambda = dI/dy$ is the current per unit length along the y axis.

Picture the Problem In Parts (*a*), (*b*), and (*c*) we can use a right-hand rule to determine the direction of the magnetic field at points above and below the infinite sheet of current. In Part (*d*) we can evaluate $\oint_C \vec{B}\cdot d\vec{\ell}$ around the specified path and equate it to $\mu_0 I_C$ and solve for B.

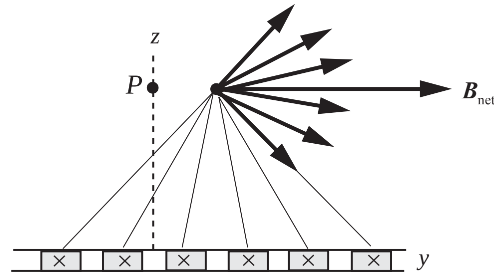
(*a*) Because its vertical components cancel at P, the magnetic field points to the right (i.e., in the $+y$ direction).



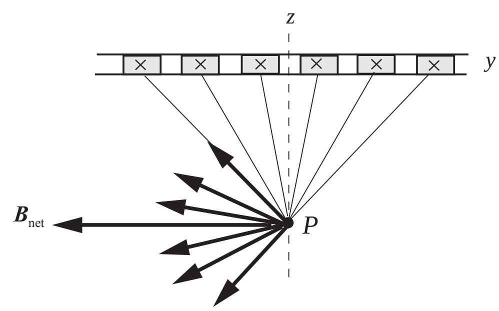
(*b*) The vertical components of the field cancel in pairs. The magnetic field is in the $+y$ direction.



(*c*) The magnetic field is in the +*y* direction. This result follows from the same arguments that were used in (*a*) and (*b*).



(*d*) Below the sheet the magnetic field points to the left; i.e., in the −*y* direction. The vertical components cancel in pairs.



(*e*) Express $\oint_C \vec{B}\cdot d\vec{\ell}$, in the counterclockwise direction, for the given path:

$$\oint_C \vec{B}\cdot d\vec{\ell} = 2\int_{\text{parallel}} \vec{B}\cdot d\vec{\ell} + 2\int_{\perp} \vec{B}\cdot d\vec{\ell} \quad (1)$$

For the paths perpendicular to the sheet, $\vec{B}$ and $d\vec{\ell}$ are perpendicular to each other and:

$$\int_{\perp} \vec{B}\cdot d\vec{\ell} = 0$$

For the paths parallel to the sheet, $\vec{B}$ and $d\vec{\ell}$ are in the same direction and:

$$\int_{\text{parallel}} \vec{B}\cdot d\vec{\ell} = Bw$$

Substituting in equation (1) and simplifying yields:

$$\oint_C \vec{B}\cdot d\vec{\ell} = 2\int_{\text{parallel}} \vec{B}\cdot d\vec{\ell} = 2Bw$$
$$= \mu_0 I_C = \mu_0(\lambda w)$$

Solving for *B* yields:

$$B = \boxed{\tfrac{1}{2}\mu_0\lambda}$$

Magnetization and Magnetic Susceptibility

53 • [SSM] A tightly wound solenoid is 20.0-cm long, has 400 turns, and carries a current of 4.00 A so that its axial field is in the +z direction. Find B and B_{app} at the center when (*a*) there is no core in the solenoid, and (*b*) there is a soft iron core that has a magnetization of 1.2×10^6 A/m.

Picture the Problem We can use $B = B_{\text{app}} = \mu_0 nI$ to find B and B_{app} at the center when there is no core in the solenoid and $B = B_{\text{app}} + \mu_0 M$ when there is an iron core with a magnetization $M = 1.2 \times 10^6$ A/m.

(*a*) Express the magnetic field, in the absence of a core, in the solenoid :

$$B = B_{\text{app}} = \mu_0 nI$$

Substitute numerical values and evaluate B and B_{app}:

$$B = B_{\text{app}} = \left(4\pi \times 10^{-7}\ \text{N/A}^2\right)\left(\frac{400}{0.200\,\text{m}}\right)(4.00\,\text{A}) = \boxed{10.1\,\text{mT}}$$

(*b*) With an iron core with a magnetization $M = 1.2 \times 10^6$ A/m present:

$$B_{\text{app}} = \boxed{10.1\,\text{mT}}$$

and

$$B = B_{\text{app}} + \mu_0 M = 10.1\,\text{mT} + \left(4\pi \times 10^{-7}\ \text{N/A}^2\right)\left(1.2 \times 10^6\ \text{A/m}\right) = \boxed{1.5\,\text{T}}$$

54 • A long tungsten-core solenoid carries a current. (*a*) If the core is removed while the current is held constant, does the magnetic field strength in the region inside the solenoid decrease or increase? (*b*) By what percentage does the magnetic field strength in the region inside the solenoid decrease or increase?

Picture the Problem We can use $B = B_{\text{app}}(1 + \chi_{\text{m}})$ to relate B and B_{app} to the magnetic susceptibility of tungsten. Dividing both sides of this equation by B_{app} and examining the value of $\chi_{\text{m, tungsten}}$ will allow us to decide whether the field inside the solenoid decreases or increases when the core is removed.

Express the magnetic field inside the solenoid with the tungsten core present B in terms of B_{app} and χ_{m}:

$$B = B_{\text{app}}(1 + \chi_{\text{m}})$$

where B_{app} is the magnetic field in the absence of the tungsten core.

Express the ratio of B to B_{app} :

$$\frac{B}{B_{\text{app}}} = 1 + \chi_{\text{m}} \qquad (1)$$

(*a*) Because $\chi_{\text{m, tungsten}} > 0$:

$B > B_{\text{app}}$ and B will decrease when the tungsten core is removed.

(*b*) From equation (1), the fractional change is:

$$\chi_m = 6.8\times10^{-5} = \boxed{6.8\times10^{-3}\%}$$

55 • As a liquid fills the interior volume of a solenoid that carries a constant current, the magnetic field inside the solenoid *decreases* by 0.0040 percent. Determine the magnetic susceptibility of the liquid.

Picture the Problem We can use $B = B_{app}(1+\chi_m)$ to relate B and B_{app} to the magnetic susceptibility of liquid sample.

Express the magnetic field inside the solenoid with the liquid sample present B in terms of B_{app} and $\chi_{m,\,sample}$:

$$B = B_{app}(1+\chi_{m,\,sample})$$

where B_{app} is the magnetic field in the absence of the liquid sample.

The fractional change in the magnetic field in the core is:

$$\frac{\Delta B}{B_{app}} = \chi_{m,\,sample}$$

Substitute numerical values and evaluate $\chi_{m,\,sample}$:

$$\chi_{m,\,sample} = \frac{\Delta B}{B_{app}} = -0.0040\%$$

$$= \boxed{-4.0\times10^{-5}}$$

56 • A long thin solenoid carrying a current of 10 A has 50 turns per centimeter of length. What is the magnetic field strength in the region occupied by the interior of the solenoid when the interior is (*a*) a vacuum, (*b*) filled with aluminum, and (*c*) filled with silver?

Picture the Problem We can use $B = B_{app} = \mu_0 nI$ to find B and B_{app} at the center when there is no core in the solenoid and $B = B_{app}(1+\chi_m)$ when there is an aluminum or silver core.

(*a*) Express the magnetic field, in the absence of a core, in the solenoid:

$$B = B_{app} = \mu_0 nI$$

Substitute numerical values and evaluate B and B_{app}:

$$B = B_{app} = \left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(\frac{50}{\text{cm}}\right)(10\ \text{A}) = \boxed{63\,\text{mT}}$$

(*b*) With an aluminum core:

$$B = B_{app}(1+\chi_m)$$

Use Table 27-1 to find the value of χ_m for aluminum:

$$\chi_{\mathrm{m,\,Al}} = 2.3\times10^{-5}$$
and
$$1+\chi_{\mathrm{m,\,Al}} = 1+2.3\times10^{-5} \approx 1$$

Substitute numerical values and evaluate B and B_{app}:

$$B = B_{\mathrm{app}} = \left(4\pi\times10^{-7}\ \mathrm{N/A^2}\right)\left(\frac{50}{\mathrm{cm}}\right)\left(10\,\mathrm{A}\right) = \boxed{63\,\mathrm{mT}}$$

(c) With a silver core:

$$B = B_{\mathrm{app}}\left(1+\chi_{\mathrm{m}}\right)$$

Use Table 27-1 to find the value of χ_m for silver:

$$\chi_{\mathrm{m,\,Ag}} = -2.6\times10^{-5}$$
and
$$1+\chi_{\mathrm{m,\,Ag}} = 1-2.6\times10^{-5} \approx 1$$

Substitute numerical values and evaluate B and B_{app}:

$$B = B_{\mathrm{app}} = \left(4\pi\times10^{-7}\ \mathrm{N/A^2}\right)\left(\frac{50}{\mathrm{cm}}\right)\left(10\,\mathrm{A}\right) = \boxed{63\,\mathrm{mT}}$$

57 •• [SSM] A cylinder of iron, initially unmagnetized, is cooled to 4.00 K. What is the magnetization of the cylinder at that temperature due to the influence of Earth's magnetic field of 0.300 G? Assume a magnetic moment of 2.00 Bohr magnetons per atom.

Picture the Problem We can use Curie's law to relate the magnetization M of the cylinder to its saturation magnetization M_S. The saturation magnetization is the product of the number of atoms n in the cylinder and the magnetic moment of each molecule. We can find n using the proportion $\dfrac{n}{N_A} = \dfrac{\rho_{\mathrm{Fe}}}{M_{\mathrm{Fe}}}$ where M_{Fe} is the molar mass of iron.

The magnetization of the cylinder is given by Curie's law:

$$M = \frac{1}{3}\frac{\mu B_{\mathrm{app}}}{kT}M_{\mathrm{S}}$$

Assuming a magnetic moment of 2.00 Bohr magnetons per atom:

$$M = \frac{1}{3}\frac{\left(2.00\mu_{\mathrm{B}}\right)B_{\mathrm{Earth}}}{kT}M_{\mathrm{S}} \qquad (1)$$

The saturation magnetization is given by:

$$M_S = n\mu = n(2.00\mu_B)$$

where n is the number of atoms and μ is the magnetic moment of each molecule.

The number of atoms of iron per unit volume n can be found from the molar mass M_{Fe} of iron, the density ρ_{Fe} of iron, and Avogadro's number N_A:

$$n = \frac{\rho_{Fe}}{M_{Fe}} N_A \Rightarrow M_S = \frac{2.00\rho_{Fe} N_A \mu_B}{M_{Fe}}$$

Substitute numerical values and evaluate M_S:

$$M_S = \frac{2.00\left(7.96\times10^3 \frac{\text{kg}}{\text{m}^3}\right)\left(6.022\times10^{23} \frac{\text{atoms}}{\text{mol}}\right)\left(9.27\times10^{-24}\ \text{A}\cdot\text{m}^2\right)}{55.85\frac{\text{g}}{\text{mol}}\times\frac{1\,\text{kg}}{10^3\ \text{g}}}$$

$$= 1.591\times10^6\ \frac{\text{A}}{\text{m}}$$

Substitute numerical values in equation (1) and evaluate M:

$$M = \frac{2.00\left(5.788\times10^{-5}\ \frac{\text{eV}}{\text{T}}\right)\left(0.300\ \text{G}\times\frac{1\,\text{T}}{10^4\ \text{G}}\right)}{3\left(8.617\times10^{-5}\ \frac{\text{eV}}{\text{K}}\right)(4.00\ \text{K})}\left(1.591\times10^6\ \frac{\text{A}}{\text{m}}\right) = \boxed{5.34\frac{\text{A}}{\text{m}}}$$

58 •• A cylinder of silver at a temperature of 77 K has a magnetization equal to 0.075% of its saturation magnetization. Assume a magnetic moment of one Bohr magneton per atom. The density of silver is 1.05×10^4 kg/m^3. (*a*) What value of applied magnetic field parallel to the central axis of the cylinder is required to reach this magnetization? (*b*) What is the magnetic field strength at the center of the cylinder?

Picture the Problem We can use Curie's law to relate the magnetization M of the cylinder to its saturation magnetization M_S. The saturation magnetization is the product of the number of atoms n in the cylinder and the magnetic moment of each atom. We can find n using the proportion $\frac{n}{N_A} = \frac{\rho_{Ag}}{\text{M}_{Ag}}$ where M_{Ag} is the molar mass of silver. In Part (*b*), we can use Equation 27-22 to find the magnetic field at the center of the cylinder, on the axis defined by the magnetic field.

(*a*) The magnetization of the cylinder is given by Curie's law:

$$M = \frac{1}{3}\frac{\mu B_{\text{app}}}{kT} M_{\text{S}}$$

Assuming a magnetic moment of 1Bohr magnetons per atom:

$$M = \frac{(\mu_{\text{B}})B_{\text{app}}}{3kT} M_{\text{S}} \Rightarrow B_{\text{app}} = \frac{3kT}{\mu_{\text{B}}}\left(\frac{M}{M_{\text{S}}}\right)$$

Substitute numerical values and evaluate B_{app}:

$$B_{\text{app}} = \frac{3\left(8.617\times10^{-5}\ \frac{\text{eV}}{\text{K}}\right)(77\ \text{K})}{5.788\times10^{-5}\ \frac{\text{eV}}{\text{T}}}(0.00075) = \boxed{0.26\ \text{T}}$$

(*b*) The magnetic field at the center of the cylinder on the axis defined by the magnetic field is:

$$B = B_{\text{app}} + \mu_0 M_{\text{S}} \qquad (1)$$

The saturation magnetization is given by:

$$M_{\text{S}} = n\mu = n(\mu_{\text{B}})$$

where n is the number of atoms and μ is the magnetic moment of each molecule.

The number of atoms of silver per unit volume n can be found from the molar mass M_{Ag} of silver, the density ρ_{Ag} of silver, and Avogadro's number N_{A}:

$$n = \frac{\rho_{\text{Ag}}}{M_{\text{Ag}}} N_{\text{A}} \Rightarrow M_{\text{S}} = \frac{\rho_{\text{Ag}} N_{\text{A}} \mu_{\text{B}}}{M_{\text{Ag}}}$$

Substitute numerical values and evaluate M_{S}:

$$M_{\text{S}} = \frac{\left(10.5\times10^3\ \frac{\text{kg}}{\text{m}^3}\right)\left(6.022\times10^{23}\ \frac{\text{atoms}}{\text{mol}}\right)\left(9.27\times10^{-24}\ \text{A}\cdot\text{m}^2\right)}{107.870\frac{\text{g}}{\text{mol}}\times\frac{1\,\text{kg}}{10^3\ \text{g}}} = 5.434\times10^5\ \frac{\text{A}}{\text{m}}$$

Substitute numerical values in equation (1) and evaluate B:

$$B = 0.26\ \text{T} + \left(4\pi\times10^{-7}\ \text{T}\cdot\text{A}\right)\left(5.434\times10^5\ \frac{\text{A}}{\text{m}}\right) = \boxed{0.94\ \text{T}}$$

59 •• During a solid-state physics lab, you are handed a cylindrically shaped sample of unknown magnetic material. You and your lab partners place the sample in a long solenoid that has n turns per unit length and a current I. The values for magnetic field B within the material versus nI, where B_{app} is the field due to the current I and K_m is the relative permeability of the sample, are given below. Use these values to plot B versus B_{app} and K_m versus nI.

nI, A/m	0	50	100	150	200	500	1000	10 000
B, T	0	0.04	0.67	1.00	1.2	1.4	1.6	1.7

Picture the Problem We can use the data in the table and $B_{app} = \mu_0 nI$ to plot B versus B_{app}. We can find K_m using $B = K_m B_{app}$.

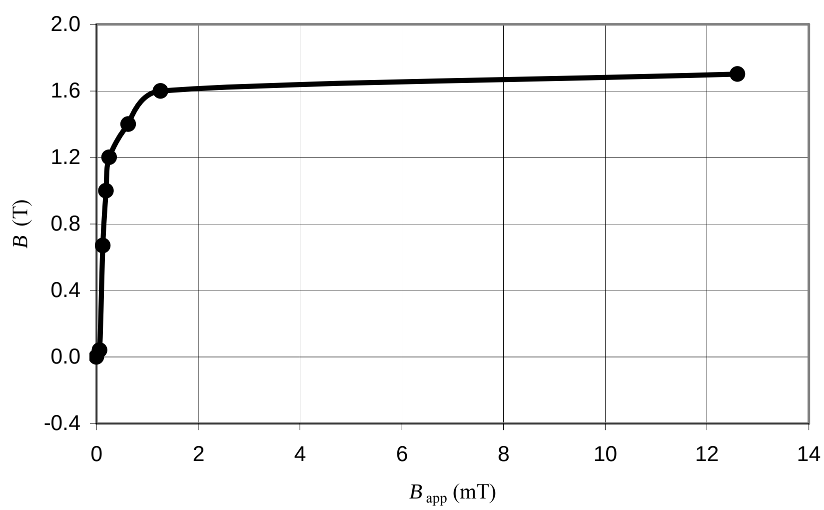
We can find the applied field B_{app} for a long solenoid using:

$$B_{app} = \mu_0 nI$$

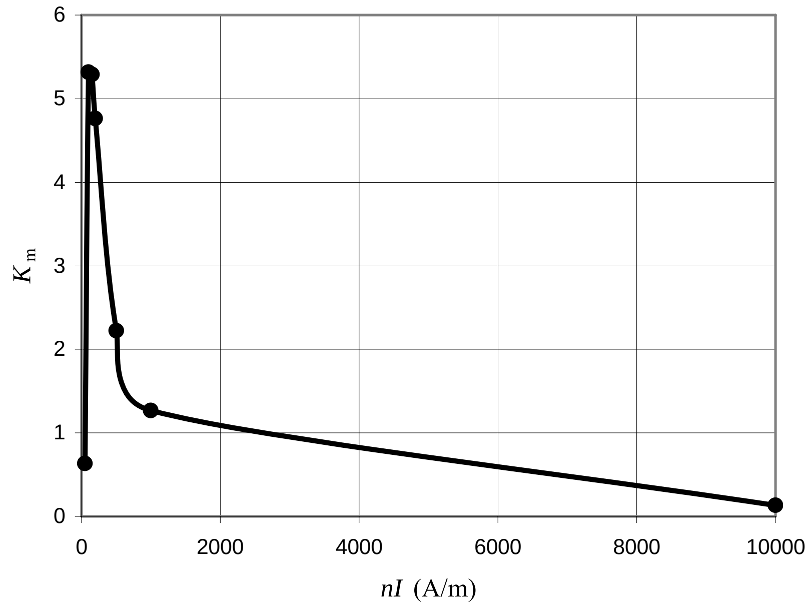
K_m can be found from B_{app} and B using:

$$K_m = \frac{B}{B_{app}}$$

The following graph was plotted using a spreadsheet program. The abscissa values for the graph were obtained by multiplying nI by μ_0. B initially rises rapidly, and then becomes nearly flat. This is characteristic of a ferromagnetic material.



The following graph of K_m versus nI was also plotted using a spreadsheet program. Note that K_m becomes quite large for small values of nI but then diminishes. A more revealing graph would be to plot $B/(nI)$, which would be quite large for small values of nI and then drop to nearly zero at nI = 10,000 A/m, corresponding to saturation of the magnetization.



Atomic Magnetic Moments

60 •• Nickel has a density of 8.70 g/cm^3 and a molar mass of 58.7 g/mol. Nickel's saturation magnetization is 0.610 T. Calculate the magnetic moment of a nickel atom in Bohr magnetons.

Picture the Problem We can find the magnetic moment of a nickel atom μ from its relationship to the saturation magnetization M_S using $M_S = n\mu$ where n is the number of molecules per unit volume. n, in turn, can be found from Avogadro's number, the density of nickel, and its molar mass using $n = \frac{N_A\rho}{M}$.

Express the saturation magnetic field in terms of the number of molecules per unit volume and the magnetic moment of each molecule:

$$M_S = n\mu \Rightarrow \mu = \frac{M_S}{n}$$

Express the number of molecules per unit volume in terms of Avogadro's number N_A, the molecular mass M, and the density ρ:

$$n = \frac{N_A \rho}{M}$$

Substitute for n in the equation for μ and simplify to obtain:

$$\mu = \frac{M_S}{\frac{N_A \rho}{M}} = \frac{\mu_0 M_S}{\frac{\mu_0 N_A \rho}{M}} = \frac{\mu_0 M_S M}{\mu_0 N_A \rho}$$

Substitute numerical values and evaluate μ:

$$\mu = \frac{(0.610\,T)(58.7\times10^{-3}\,\text{kg/mol})}{(4\pi\times10^{-7}\,\text{N/A}^2)(6.022\times10^{23}\,\text{atoms/mol})(8.70\,\text{g/cm}^3)} = 5.439\times10^{-24}\,\text{A}\cdot\text{m}^2$$

Divide μ by $\mu_B = 9.27\times10^{-24}\,\text{A}\cdot\text{m}^2$ to obtain:

$$\frac{\mu}{\mu_B} = \frac{5.439\times10^{-24}\,\text{A}\cdot\text{m}^2}{9.27\times10^{-24}\,\text{A}\cdot\text{m}^2} = 0.587$$

or $\mu = \boxed{0.587\mu_B}$

61 •• Repeat Problem 60 for cobalt, which has a density of 8.90 g/cm^3, a molar mass of 58.9 g/mol, and a saturation magnetization of 1.79 T.

Picture the Problem We can find the magnetic moment of a cobalt atom μ from its relationship to the saturation magnetization M_S using $M_S = n\mu$, where n is the number of molecules per unit volume. n, in turn, can be found from Avogadro's number, the density of cobalt, and its molar mass using $n = \frac{N_A \rho}{M}$.

Express the saturation magnetic field in terms of the number of molecules per unit volume and the magnetic moment of each molecule:

$$M_S = n\mu \Rightarrow \mu = \frac{M_S}{n}$$

Express the number of molecules per unit volume in terms of Avogadro's number N_A, the molar mass M, and the density ρ:

$$n = \frac{N_A \rho}{M}$$

Substitute for n in the equation for μ and simplify to obtain:

$$\mu = \frac{M_S}{\frac{N_A \rho}{M}} = \frac{\mu_0 M_S}{\frac{\mu_0 N_A \rho}{M}} = \frac{\mu_0 M_S M}{\mu_0 N_A \rho}$$

Substitute numerical values and evaluate μ:

$$\mu = \frac{(1.79\,\text{T})(58.9\times10^{-3}\,\text{kg/mol})}{(4\pi\times10^{-7}\,\text{N/A}^2)(6.022\times10^{23}\,\text{atoms/mol})(8.90\,\text{g/cm}^3)} = 1.57\times10^{-23}\,\text{A}\cdot\text{m}^2$$

Divide μ by $\mu_B = 9.27\times10^{-24}\,\text{A}\cdot\text{m}^2$ to obtain:

$$\frac{\mu}{\mu_B} = \frac{1.57\times10^{-23}\,\text{A}\cdot\text{m}^2}{9.27\times10^{-24}\,\text{A}\cdot\text{m}^2} = 1.69$$

or $\mu = \boxed{1.69\mu_B}$

Paramagnetism

62 • Show that Curie's law predicts that the magnetic susceptibility of a paramagnetic substance is given by $\chi_m = \mu\mu_0 M_s/3kT$.

Picture the Problem We can show that $\chi_m = \mu\mu_0 M_s/3kT$ by equating Curie's law and the equation that defines χ_m ($M = \chi_m \frac{B_{app}}{\mu_0}$) and solving for χ_m.

Express Curie's law:

$$M = \frac{1}{3}\frac{\mu B_{app}}{kT} M_S$$

where M_S is the saturation value.

Express the magnetization of the substance in terms of its magnetic susceptibility χ_m:

$$M = \chi_m \frac{B_{app}}{\mu_0}$$

Equate these expressions to obtain:

$$\chi_m \frac{B_{app}}{\mu_0} = \frac{1}{3}\frac{\mu B_{app}}{kT} M_S$$

and

$$\frac{\chi_m}{\mu_0} = \frac{1}{3}\frac{\mu}{kT} M_S \Rightarrow \chi_m = \boxed{\frac{\mu_0 \mu M_S}{3kT}}$$

63 •• In a simple model of paramagnetism, we can consider that some fraction f of the molecules have their magnetic moments aligned with the external magnetic field and that the rest of the molecules are randomly oriented and therefore do not contribute to the magnetic field. (*a*) Use this model and Curie's law to show that at temperature T and external magnetic field B, the fraction of aligned molecules f is given by $\mu B/(3kT)$. (*b*) Calculate this fraction for a sample temperature of 300 K, an external field of 1.00 T. Assume that μ has a value of 1.00 Bohr magneton.

Picture the Problem We can use the assumption that $M = fM_S$ and Curie's law to solve these equations simultaneously for the fraction *f* of the molecules have their magnetic moments aligned with the external magnetic field.

(*a*) Assume that some fraction *f* of the molecules have their magnetic moments aligned with the external magnetic field and that the rest of the molecules are randomly oriented and so do not contribute to the magnetic field:

$$M = fM_S$$

From Curie's law we have:

$$M = \frac{1}{3}\frac{\mu B_{app}}{kT}M_S$$

Equating these expressions yields:

$$fM_S = \frac{1}{3}\frac{\mu B_{app}}{kT}M_S \Rightarrow f = \boxed{\frac{\mu B}{3kT}}$$

because B given in the problem statement is the external magnetic field B_{app} .

(*b*) Substitute numerical values and evaluate *f*:

$$f = \frac{(9.27\times10^{-24}\ \text{A}\cdot\text{m}^2)(1.00\,\text{T})}{3(1.381\times10^{-23}\ \text{J/K})(300\,\text{K})} = \boxed{7.46\times10^{-4}}$$

64 •• Assume that the magnetic moment of an aluminum atom is 1.00 Bohr magneton. The density of aluminum is 2.70 g/cm^3 and its molar mass is 27.0 g/mol. (*a*) Calculate the value of the saturation magnetization and the saturation magnetic field for aluminum. (*b*) Use the result of Problem 62 to calculate the magnetic susceptibility at 300 K. (*c*) Explain why the result for Part (*b*) is larger than the value listed in Table 27-1.

Picture the Problem In (*a*) we can express the saturation magnetic field in terms of the number of molecules per unit volume and the magnetic moment of each molecule and use $n = N_A\rho/\text{M}$ to express the number of molecules per unit volume in terms of Avogadro's number N_A, the molecular mass M, and the density ρ. (*b*) We can use $\chi_m = \mu_0\mu M_S/3kT$ from Problem 62 to calculate χ_m.

(*a*) Express the saturation magnetic field in terms of the number of molecules per unit volume and the magnetic moment of each molecule:

$$M_S = n\mu_B$$

Express the number of molecules per unit volume in terms of Avogadro's number N_A, the molecular mass M, and the density ρ:

$$n = \frac{N_A \rho}{\text{M}}$$

Substitute for *n* to obtain:

$$M_S = \frac{N_A \rho}{\text{M}} \mu_B$$

Substitute numerical values and evaluate M_S:

$$M_S = \frac{(6.022 \times 10^{23}\ \text{atoms/mol})(2.70 \times 10^3\ \text{kg/m}^3)(9.27 \times 10^{-24}\ \text{A} \cdot \text{m}^2)}{27.0\,\text{g/mol}}$$
$$= 5.582 \times 10^5\ \text{A/m} = \boxed{5.58 \times 10^5\ \text{A/m}}$$

and

$$B_S = \mu_0 M_S = (4\pi \times 10^{-7}\ \text{N/A}^2)(5.582 \times 10^5\ \text{A/m}) = \boxed{0.702\,\text{T}}$$

(*b*) From Problem 62 we have:

$$\chi_m = \frac{\mu_0 \mu M_S}{3kT}$$

Substitute numerical values and evaluate χ_m:

$$\chi_m = \frac{(4\pi \times 10^{-7}\ \text{N/A}^2)(9.27 \times 10^{-24}\ \text{A} \cdot \text{m}^2)(5.582 \times 10^5\ \text{A/m})}{3(1.381 \times 10^{-23}\ \text{J/K})(300\,\text{K})} = \boxed{5.23 \times 10^{-4}}$$

(*c*) In calculating χ_m in Part (*b*) we neglected any diamagnetic effects.

65 •• [SSM] A toroid has *N* turns, carries a current *I*, has a mean radius *R*, and has a cross-sectional radius *r*, where $r \ll R$ (Figure 27-59). When the toroid is filled with material, it is called a *Rowland ring*. Find B_{app} and *B* in such a ring, assuming a magnetization that is everywhere parallel to $\vec{B}_{app}$.

Picture the Problem We can use $B_{app} = \dfrac{\mu_0 NI}{2\pi a}$ to express B_{app} and $B = B_{app} + \mu_0 M$ express *B* in terms of B_{app} and *M*.

Express B_{app} inside a tightly wound toroid:

$$B_{\text{app}} = \boxed{\frac{\mu_0 NI}{2\pi a}} \text{ for } R - r < a < R + r$$

The resultant field B in the ring is the sum of B_{app} and $\mu_0 M$:

$$B = B_{\text{app}} + \mu_0 M = \boxed{\frac{\mu_0 NI}{2\pi a} + \mu_0 M}$$

66 •• A toroid is filled with liquid oxygen that has a magnetic susceptibility of 4.00×10^{-3}. The toroid has 2000 turns and carries a current of 15.0 A. Its mean radius is 20.0 cm, and the radius of its cross section is 8.00 mm. (*a*) What is the magnetization? (*b*) What is the magnetic field? (*c*) What is the percentage change in magnetic field produced by the liquid oxygen?

Picture the Problem We can find the magnetization using $M = \chi_{\text{m}} B_{\text{app}} / \mu_0$ and the magnetic field using $B = B_{\text{app}}(1 + \chi_{\text{m}})$.

(*a*) The magnetization M in terms of χ_{m} and B_{app} is given by:

$$M = \chi_{\text{m}} \frac{B_{\text{app}}}{\mu_0}$$

Express B_{app} inside a tightly wound toroid:

$$B_{\text{app}} = \frac{\mu_0 NI}{2\pi r_{\text{mean}}}$$

Substitute for B_{app} to obtain:

$$M = \chi_{\text{m}} \frac{\dfrac{\mu_0 NI}{2\pi r_{\text{mean}}}}{\mu_0} = \chi_{\text{m}} \frac{NI}{2\pi r_{\text{mean}}}$$

Substitute numerical values and evaluate M:

$$M = \frac{(4.00 \times 10^{-3})(2000)(15.0\,\text{A})}{2\pi(0.200\,\text{m})} = \boxed{95.5\,\text{A/m}}$$

(*b*) Express B in terms of B_{app} and χ_{m}:

$$B = B_{\text{app}}(1 + \chi_{\text{m}})$$

Substitute for B_{app} to obtain:

$$B = \frac{\mu_0 NI}{2\pi r_{\text{mean}}}(1 + \chi_{\text{m}})$$

Substitute numerical values and evaluate B:

$$B = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(2000)(15.0\,\text{A})}{2\pi(0.200\,\text{m})}\left(1+4.00\times10^{-3}\right) = \boxed{30.1\,\text{mT}}$$

(c) Express the fractional increase in B produced by the liquid oxygen:

$$\frac{\Delta B}{B} = \frac{B - B_{\text{app}}}{B} = \frac{B_{\text{app}}(1+\chi_{\text{m}}) - B_{\text{app}}}{B} = \frac{\chi_{\text{m}} B_{\text{app}}}{B} = \frac{\chi_{\text{m}}}{1+\chi_{\text{m}}} = \frac{1}{\dfrac{1}{\chi_{\text{m}}}+1}$$

Substitute numerical values and evaluate $\Delta B/B$:

$$\frac{\Delta B}{B} = \frac{1}{\dfrac{1}{4.00\times10^{-3}}+1} = 3.98\times10^{-3} = \boxed{0.398\%}$$

67 •• The centers of the turns of a toroid form a circle with a radius of 14.0 cm. The cross-sectional area of each turn is 3.00 cm^2. It is wound with 5278 turns of fine wire, and the wire carries a current of 4.00 A. The core is filled with a paramagnetic material of magnetic susceptibility 2.90×10^{-4}. (a) What is the magnitude of the magnetic field within the substance? (b) What is the magnitude of the magnetization? (c) What would the magnitude of the magnetic field be if there were no paramagnetic core present?

Picture the Problem We can use $B = B_{\text{app}}(1+\chi_{\text{m}})$ and $B_{\text{app}} = \dfrac{\mu_0 NI}{2\pi r_{\text{mean}}}$ to find B within the substance and $M = \chi_{\text{m}}\dfrac{B_{\text{app}}}{\mu_0}$ to find the magnitude of the magnetization.

(a) Express the magnetic field B within the substance in terms of B_{app} and χ_{m}:

$$B = B_{\text{app}}(1+\chi_{\text{m}})$$

Express B_{app} inside the toroid:

$$B_{\text{app}} = \frac{\mu_0 NI}{2\pi r_{\text{mean}}}$$

Substitute to obtain:

$$B = \frac{\mu_0 NI(1+\chi_m)}{2\pi r_{mean}}$$

Substitute numerical values and evaluate B:

$$B = \frac{(4\pi \times 10^{-7}\ \mathrm{N/A^2})(5278)(4.00\ \mathrm{A})(1+2.90\times 10^{-4})}{2\pi(14.0\ \mathrm{cm})} = \boxed{30.2\ \mathrm{mT}}$$

(*b*) Express the magnetization M in terms of χ_m and B_{app}:

$$M = \chi_m \frac{B_{app}}{\mu_0}$$

Substitute for B_{app} and simplify to obtain:

$$M = \frac{\chi_m NI}{2\pi r_{mean}}$$

Substitute numerical values and evaluate M:

$$M = \frac{(2.90\times 10^{-4})(5278)(4.00\ \mathrm{A})}{2\pi(14.0\ \mathrm{cm})} = \boxed{6.96\ \mathrm{A/m}}$$

(*c*) If there were no paramagnetic core present:

$$B = B_{app} = \boxed{30.2\ \mathrm{mT}}$$

Ferromagnetism

68 • For annealed iron, the relative permeability K_m has its maximum value of approximately 5500 at $B_{app} = 1.57 \times 10^{-4}$ T. Find the magnitude of the magnetization and magnetic field in annealed iron when K_m is maximum.

Picture the Problem We can use $B = K_m B_{app}$ to find B and $M = (K_m - 1)B_{app}/\mu_0$ to find M.

Express B in terms of M and K_m:

$$B = K_m B_{app}$$

Substitute numerical values and evaluate B:

$$B = (5500)(1.57\times 10^{-4}\ \mathrm{T}) = \boxed{0.86\ \mathrm{T}}$$

Relate M to K_m and B_{app}:

$$M = (K_m - 1)\frac{B_{app}}{\mu_0} \approx \frac{K_m B_{app}}{\mu_0}$$

Substitute numerical values and evaluate M:

$$M = \frac{(5500)(1.57\times10^{-4}\ \text{T})}{4\pi\times10^{-7}\ \text{N/A}^2} = \boxed{6.9\times10^{5}\ \text{A/m}}$$

69 •• **[SSM]** The saturation magnetization for annealed iron occurs when B_{app} = 0.201 T. Find the permeability and the relative permeability of annealed iron at saturation. (See Table 27-2)

Picture the Problem We can relate the permeability μ of annealed iron to χ_{m} using $\mu = (1+\chi_{\text{m}})\mu_0$, find χ_{m} using $M = \chi_{\text{m}}\dfrac{B_{\text{app}}}{\mu_0}$, and use its definition ($K_{\text{m}} = 1+\chi_{\text{m}}$) to evaluate K_{m}.

Express the permeability μ of annealed iron in terms of its magnetic susceptibility χ_{m}:

$$\mu = (1+\chi_{\text{m}})\mu_0 \qquad (1)$$

The magnetization M in terms of χ_{m} and B_{app} is given by:

$$M = \chi_{\text{m}}\frac{B_{\text{app}}}{\mu_0}$$

Solve for and evaluate χ_{m} (see Table 27-2 for the product of μ_0 and M):

$$\chi_{\text{m}} = \frac{\mu_0 M}{B_{\text{app}}} = \frac{2.16\,\text{T}}{0.201\,\text{T}} = 10.75$$

Use its definition to express and evaluate the relative permeability K_{m}:

$$K_{\text{m}} = 1+\chi_{\text{m}} = 1+10.75 = 11.746 = \boxed{11.7}$$

Substitute numerical values in equation (1) and evaluate μ:

$$\mu = (1+10.746)(4\pi\times10^{-7}\ \text{N/A}^2) = \boxed{1.48\times10^{-5}\,\text{N/A}^2}$$

70 •• The *coercive force* (which is a misnomer because it is really a magnetic field value) is defined as the applied magnetic field needed to bring the magnetic field back to zero along the hysteresis curve (which is point *c* in Figure 27- 38). For a certain permanent bar magnet, the coercive force is known to be 5.53×10^{-2} T. The bar magnet is to be demagnetized by placing it inside a 15.0-cm-long solenoid that has 600 turns. What minimum current is needed in the solenoid to demagnetize the magnet?

Picture the Problem We can use the relationship between the magnetic field on the axis of a solenoid and the current in the solenoid to find the minimum current is needed in the solenoid to demagnetize the magnet.

Relate the magnetic field on the axis of a solenoid to the current in the solenoid:

$$B_x = \mu_0 nI \Rightarrow I = \frac{B_x}{\mu_0 n}$$

Let $B_{\text{app}} = B_x$ to obtain:

$$I = \frac{B_{\text{app}}}{\mu_0 n}$$

Substitute numerical values and evaluate I:

$$I = \frac{5.53\times10^{-2}\ \text{T}}{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(\dfrac{600}{0.150\,\text{m}}\right)} = \boxed{11.0\,\text{A}}$$

71 •• A long thin solenoid has 50 turns/cm and carries a current of 2.00 A. The solenoid is filled with iron and the magnetic field is measured to be 1.72 T. (*a*) Neglecting end effects, what is the magnitude of the applied magnetic field? (*b*) What is the magnetization? (*c*) What is the relative permeability?

Picture the Problem We can use the equation describing the magnetic field on the axis of a solenoid, as a function of the current in the solenoid, to find B_{app}. We can then use $B = B_{\text{app}} + \mu_0 M$ to find M and $B = K_{\text{m}} B_{\text{app}}$ to evaluate K_{m}.

(*a*) Relate the magnetic field on the axis of a solenoid to the current in the solenoid:

$$B_x = \mu_0 nI$$

Substitute numerical values and evaluate B_{app}:

$$B_{\text{app}} = \left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(50\,\text{cm}^{-1}\right)\left(2.00\,\text{A}\right) = \boxed{12.6\,\text{mT}}$$

(*b*) Relate M to B and B_{app}:

$$B = B_{\text{app}} + \mu_0 M \Rightarrow M = \frac{B - B_{\text{app}}}{\mu_0}$$

Substitute numerical values and evaluate M:

$$M = \frac{1.72\,\text{T} - 12.6\,\text{mT}}{4\pi\times10^{-7}\ \text{N/A}^2} = \boxed{1.36\times10^{6}\ \text{A/m}}$$

(*c*) Express B in terms of K_m and B_{app}:

$$B = K_m B_{app} \Rightarrow K_m = \frac{B}{B_{app}}$$

Substitute numerical values and evaluate K_m:

$$K_m = \frac{1.72\,\text{T}}{12.6\,\text{mT}} = \boxed{137}$$

72 •• When the current in Problem 71 is 0.200 A, the magnetic field is measured to be 1.58 T. (*a*) Neglecting end effects, what is the applied magnetic field? (*b*) What is the magnetization? (*c*) What is the relative permeability?

Picture the Problem We can use the equation describing the magnetic field on the axis of a solenoid, as a function of the current in the solenoid, to find B_{app}. We can then use $B = B_{app} + \mu_0 M$ to find M and $B = K_m B_{app}$ to evaluate K_m.

(*a*) Relate the magnetic field on the axis of the solenoid to the current in the solenoid:

$$B_x = \mu_0 nI$$

Substitute numerical values and evaluate B_{app}:

$$B_{app} = \left(4\pi \times 10^{-7}\,\frac{\text{N}}{\text{A}^2}\right)\left(50\,\text{cm}^{-1}\right)\left(0.200\,\text{A}\right) = 1.257\,\text{mT} = \boxed{1.26\,\text{mT}}$$

(*b*) Relate M to B and B_{app}:

$$B = B_{app} + \mu_0 M \Rightarrow M = \frac{B - B_{app}}{\mu_0}$$

Substitute numerical values and evaluate M:

$$M = \frac{1.58\,\text{T} - 1.257\,\text{mT}}{4\pi \times 10^{-7}\,\text{N/A}^2} = \boxed{1.26 \times 10^6\,\text{A/m}}$$

(*c*) Express B in terms of K_m and B_{app}:

$$B = K_m B_{app} \Rightarrow K_m = \frac{B}{B_{app}}$$

Substitute numerical values and evaluate K_m:

$$K_m = \frac{1.58\,\text{T}}{1.257\,\text{mT}} = \boxed{1.26 \times 10^3}$$

73 •• **[SSM]** A toroid has N turns, carries a current I, has a mean radius R, and has a cross-sectional radius r, where $r << R$ (Figure 27-53). The core of the toroid of is filled with iron. When the current is 10.0 A, the magnetic field in the region where the iron is has a magnitude of 1.80 T. (*a*) What is the

magnetization? (*b*) Find the values for the relative permeability, the permeability, and magnetic susceptibility for this iron sample.

Picture the Problem We can use $B = B_{app} + \mu_0 M$ and the expression for the magnetic field inside a tightly wound toroid to find the magnetization *M*. We can find K_m from its definition, $\mu = K_m \mu_0$ to find μ, and $K_m = 1 + \chi_m$ to find χ_m for the iron sample.

(*a*) Relate the magnetization to *B* and B_{app}:

$$B = B_{app} + \mu_0 M \Rightarrow M = \frac{B - B_{app}}{\mu_0}$$

Express the magnetic field inside a tightly wound toroid:

$$B_{app} = \frac{\mu_0 NI}{2\pi r}$$

Substitute for B_{app} and simplify to obtain:

$$M = \frac{B - \dfrac{\mu_0 NI}{2\pi r}}{\mu_0} = \frac{B}{\mu_0} - \frac{NI}{2\pi r}$$

Substitute numerical values and evaluate *M*:

$$M = \frac{1.80\,\text{T}}{4\pi \times 10^{-7}\ \text{N/A}^2} - \frac{2000(10.0\,\text{A})}{2\pi(0.200\,\text{m})} = \boxed{1.42 \times 10^6\ \text{A/m}}$$

(*b*) Use its definition to express K_m:

$$K_m = \frac{B}{B_{app}} = \frac{B}{\dfrac{\mu_0 NI}{2\pi r}} = \frac{2\pi r B}{\mu_0 NI}$$

Substitute numerical values and evaluate K_m:

$$K_m = \frac{2\pi(0.200\,\text{m})(1.80\,\text{T})}{(4\pi \times 10^{-7}\ \text{N/A}^2)(2000)(10.0\,\text{A})} = \boxed{90.0}$$

Now that we know K_m we can find μ using:

$$\mu = K_m \mu_0 = 90(4\pi \times 10^{-7}\ \text{N/A}^2) = \boxed{1.13 \times 10^{-4}\ \text{T} \cdot \text{m/A}}$$

Relate χ_m to K_m:

$$K_m = 1 + \chi_m \Rightarrow \chi_m = K_m - 1$$

Substitute the numerical value of K_m and evaluate χ_m:

$$\chi_m = 90 - 1 = \boxed{89}$$

74 •• The centers of the turns of a toroid form a circle with a radius of 14.0 cm. The cross-sectional area of each turn is 3.00 cm^2. It is wound with 5278 turns of fine wire, and the wire carries a current of 0.200 A. The core is filled with soft iron, which has a relative permeability of 500. What is the magnetic field strength in the core?

Picture the Problem We can substitute the expression for applied magnetic field ($B_{\text{app}} = \frac{\mu_0 NI}{2\pi r}$) in the defining equation for K_m ($B = K_m B_{\text{app}}$) to obtain an expression for the magnetic field B in the toroid.

Relate the magnetic field in the toroid to the relative permeability of its core:

$$B = K_m B_{\text{app}}$$

Express the applied magnetic field in the toroid in terms of the current in its winding:

$$B_{\text{app}} = \frac{\mu_0 NI}{2\pi r}$$

Substitute for B_{app} to obtain:

$$B = \frac{K_m \mu_0 NI}{2\pi r}$$

Substitute numerical values and evaluate B:

$$B = \frac{500\left(4\pi \times 10^{-7}\ \text{N/A}^2\right)(5278)(0.200\ \text{A})}{2\pi(14.0\ \text{cm})} = \boxed{0.754\ \text{T}}$$

75 ••• A long straight wire that has a radius of 1.00 mm is coated with an insulating ferromagnetic material that has a thickness of 3.00 mm and a relative magnetic permeability of 400. The coated wire is in air and the wire itself is nonmagnetic. The wire carries a current of 40.0 A. (*a*) Find the magnetic field in the region occupied by the inside of the wire as a function of the perpendicular distance, *r*, from the central axis of the wire. (*b*) Find the magnetic field in the region occupied by the inside of the ferromagnetic material as a function of the perpendicular distance, *r*, from the central axis of the wire. (*c*) Find the magnetic field in the region surrounding the wire and coating as a function of the perpendicular distance, *r*, from the central axis of the wire. (*d*)What must the magnitudes and directions of the Amperian currents be on the surfaces of the ferromagnetic material to account for the magnetic fields observed?

Picture the Problem We can use Ampère's law to obtain expressions for the magnetic field inside the wire, inside the ferromagnetic material, and in the region surrounding the wire and coating.

(*a*) Apply Ampère's law to a circle of radius r < 1.00 mm and concentric with the center of the wire:

$$\oint_C \vec{B}\cdot d\vec{\ell} = B(2\pi r) = \mu_0 I_C \qquad (1)$$

Assuming that the current is distributed uniformly over the cross-sectional area of the wire (uniform current density), express I_C in terms of the total current I:

$$\frac{I_C}{\pi r^2} = \frac{I}{\pi R^2} \Rightarrow I_C = \frac{r^2}{R^2} I$$

Substitute for I_C in equation (1) to obtain:

$$B(2\pi r) = \frac{\mu_0 I r^2}{R^2} \Rightarrow B = \frac{\mu_0 I}{2\pi R^2} r$$

Substitute numerical values and evaluate B:

$$B = \frac{(4\pi\times10^{-7}\ \mathrm{N/A^2})(40.0\ \mathrm{A})}{2\pi(1.00\ \mathrm{mm})^2} r = \boxed{(8.00\ \mathrm{T/m})r}$$

(*b*) Relate the magnetic field inside the ferromagnetic material to the magnetic field due to the current in the wire:

$$B = K_\mathrm{m} B_\mathrm{app} \qquad (1)$$

Apply Ampère's law to a circle of radius 1.00 mm < r < 4.00 mm and concentric with the center of the wire:

$$\int_C \vec{B}\cdot d\vec{\ell} = B_\mathrm{app}(2\pi r) = \mu_0 I_C = \mu_0 I$$

Solving for B_app yields:

$$B_\mathrm{app} = \frac{\mu_0 I}{2\pi r}$$

Substitute for B_app in equation (1) to obtain:

$$B = \frac{K_\mathrm{m}\mu_0 I}{2\pi r}$$

Substitute numerical values and evaluate B:

$$B = \frac{400(4\pi\times10^{-7}\ \mathrm{N/A^2})(40.0\ \mathrm{A})}{2\pi r} = \boxed{(3.20\times10^{-3}\ \mathrm{T\cdot m})\frac{1}{r}}$$

(*c*) Apply Ampère's law to a circle of radius $r > 4.00$ mm and concentric with the center of the wire:

$$\oint_C \vec{B}\cdot d\vec{\ell} = B(2\pi r) = \mu_0 I_C = \mu_0 I$$

Solving for B yields:

$$B = \frac{\mu_0 I}{2\pi r}$$

Substitute numerical values and evaluate B:

$$B = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(40.0\,\text{A})}{2\pi r}$$
$$= \boxed{\left(8.00\times10^{-6}\ \text{T}\cdot\text{m}\right)\frac{1}{r}}$$

(*d*) Note that the field in the ferromagnetic region is that which would be produced in a nonmagnetic region by a current of $400I$ = 1600 A. The ampèrian current on the inside of the surface of the ferromagnetic material must therefore be (1600 − 40) A = 1560 A in the direction of I. On the outside surface there must then be an ampèrian current of 1560 A in the opposite direction.

General Problems

76 • Find the magnetic field at point P in Figure 27-60.

Picture the Problem Because point P is on the line connecting the straight segments of the conductor, these segments do not contribute to the magnetic field at P. Hence, we can use the expression for the magnetic field at the center of a current loop to find B_P.

Express the magnetic field at the center of a current loop:

$$B = \frac{\mu_0 I}{2R}$$

where R is the radius of the loop.

Express the magnetic field at the center of half a current loop:

$$B = \frac{1}{2}\frac{\mu_0 I}{2R} = \frac{\mu_0 I}{4R}$$

Substitute numerical values and evaluate B:

$$B = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(15\,\text{A})}{4(0.20\,\text{m})}$$
$$= \boxed{24\,\mu\text{T out of the page}}$$

77 • [SSM] Using Figure 27-61, find the magnetic field (in terms of the parameters given in the figure) at point P, the common center of the two arcs.

Picture the Problem Let out of the page be the $+x$ direction. Because point P is on the line connecting the straight segments of the conductor, these segments do not contribute to the magnetic field at P. Hence, the resultant magnetic field at P will be the sum of the magnetic fields due to the current in the two semicircles, and we can use the expression for the magnetic field at the center of a current loop to find $\vec{B}_P$.

Express the resultant magnetic field at P:

$$\vec{B}_P = \vec{B}_1 + \vec{B}_2 \qquad (1)$$

Express the magnetic field at the center of a current loop:

$$B = \frac{\mu_0 I}{2R}$$

where R is the radius of the loop.

Express the magnetic field at the center of half a current loop:

$$B = \frac{1}{2}\frac{\mu_0 I}{2R} = \frac{\mu_0 I}{4R}$$

Express $\vec{B}_1$ and $\vec{B}_2$:

$$\vec{B}_1 = \frac{\mu_0 I}{4R_1}\hat{\boldsymbol{i}} \text{ and } \vec{B}_2 = -\frac{\mu_0 I}{4R_2}\hat{\boldsymbol{i}}$$

Substitute in equation (1) to obtain:

$$\vec{B}_P = \frac{\mu_0 I}{4R_1}\hat{\boldsymbol{i}} - \frac{\mu_0 I}{4R_2}\hat{\boldsymbol{i}}$$

$$= \boxed{\frac{\mu_0 I}{4}\left(\frac{1}{R_1} - \frac{1}{R_2}\right)\hat{\boldsymbol{i}}}$$

78 •• A wire of length ℓ, is wound into a circular coil of N turns, and carries a current I. Show that the magnetic field strength in the region occupied by the center of the coil is given by $\mu_0 \pi N^2 I/\ell$.

Picture the Problem We can express the magnetic field strength B as a function of N, I, and R using $B = \dfrac{\mu_0 NI}{2R}$ and eliminate R by relating ℓ to R.

Express the magnetic field at the center of a coil of N turns and radius R:

$$B = \frac{\mu_0 NI}{2R}$$

Relate ℓ to the number of turns N:

$$\ell = 2\pi RN \Rightarrow R = \frac{\ell}{2\pi N}$$

Substitute for R in the expression for B and simplify to obtain:

$$B = \frac{\mu_0 NI}{2\left(\frac{\ell}{2\pi N}\right)} = \boxed{\frac{\mu_0 \pi N^2 I}{\ell}}$$

79 •• A very long wire carrying a current I is bent into the shape shown in Figure 27-62. Find the magnetic field at point P.

Picture the Problem The magnetic field at P (which is out of the page) is the sum of the magnetic fields due to the three parts of the wire. Let the numerals 1, 2, and 3 denote the left-hand, center (short), and right-hand wires. Let out of the page be the $+x$ direction. We can then use the expression for B due to a straight wire segment to find each of these fields and their sum.

Express the resultant magnetic field at point P:

$$\vec{B}_P = \vec{B}_1 + \vec{B}_2 + \vec{B}_3$$

Because $\vec{B}_1 = \vec{B}_3$

$$\vec{B}_P = 2\vec{B}_1 + \vec{B}_2 \qquad (1)$$

Express the magnetic field strength due to a straight wire segment:

$$B = \frac{\mu_0}{4\pi}\frac{I}{R}\left(\sin\theta_1 + \sin\theta_2\right)$$

For wires 1 and 3 (the long wires), $\theta_1 = 90°$ and $\theta_2 = 45°$:

$$\vec{B}_1 = \frac{\mu_0}{4\pi}\frac{I}{a}\left(\sin 90° + \sin 45°\right)\hat{\boldsymbol{i}} = \frac{\mu_0}{4\pi}\frac{I}{a}\left(1 + \frac{1}{\sqrt{2}}\right)\hat{\boldsymbol{i}}$$

For wire 2, $\theta_1 = \theta_2 = 45°$:

$$\vec{B}_2 = \frac{\mu_0}{4\pi}\frac{I}{a}\left(\sin 45° + \sin 45°\right)\hat{\boldsymbol{i}} = \frac{\mu_0}{4\pi}\frac{I}{a}\left(\frac{2}{\sqrt{2}}\right)\hat{\boldsymbol{i}}$$

Substitute for $\vec{B}_1$ and $\vec{B}_2$ in equation (1) and simplify to obtain:

$$\vec{B}_P = 2\left[\frac{\mu_0}{4\pi}\frac{I}{a}\left(1+\frac{1}{\sqrt{2}}\right)\right]\hat{i} + \frac{\mu_0}{4\pi}\frac{I}{a}\left(\frac{2}{\sqrt{2}}\right)\hat{i} = \frac{\mu_0}{2\pi}\frac{I}{a}\left(1+\frac{1}{\sqrt{2}}+\frac{1}{\sqrt{2}}\right)\hat{i}$$

$$= \boxed{\frac{\mu_0}{2\pi}\frac{I}{a}\left(1+\sqrt{2}\right)\hat{i}}$$

80 •• A power cable carrying 50 A is 2.0 m below Earth's surface, but the cable's direction and precise position are unknown. Explain how you could locate the cable using a compass. Assume that you are at the equator, where Earth's magnetic field is horizontal and 0.700 G due north.

Picture the Problem Depending on the direction of the wire, the magnetic field due to its current (provided this field is a large enough fraction of Earth's magnetic field) will either add to or subtract from Earth's field and moving the compass over the ground in the vicinity of the wire will indicate the direction of the current.

Apply Ampère's law to a circle of radius r and concentric with the center of the wire:

$$\oint_C \vec{B}\cdot d\vec{\ell} = B_{\text{wire}}(2\pi r) = \mu_0 I_C = \mu_0 I$$

Solve for B to obtain:

$$B_{\text{wire}} = \frac{\mu_0 I}{2\pi r}$$

Substitute numerical values and evaluate B_{wire}:

$$B_{\text{wire}} = \frac{(4\pi\times10^{-7}\ \text{N/A}^2)(50\,\text{A})}{2\pi(2.0\,\text{m})} = 0.0500\,\text{G}$$

Express the ratio of B_{wire} to B_{Earth}:

$$\frac{B_{\text{wire}}}{B_{\text{Earth}}} = \frac{0.05\,\text{G}}{0.7\,\text{G}} \approx 7\%$$

Thus, the field of the current-carrying wire should be detectable with a good compass.

If the cable runs in a direction other than east-west, its magnetic field is in a direction different than that of Earth's, and by rotating the compass one should cause a change in the direction of the compass needle.

If the cable runs east-west, its magnetic field is in the north-south direction and thus either adds to or subtracts from Earth's field, depending on the current direction and location of the compass. If the magnetic field is toward the north, the two fields add and the resultant field is stronger. If perturbed, the compass needle will oscillate about its equilibrium position. The stronger the field, the higher the frequency of oscillation. By moving from place to place and systematically perturbing the needle one should be able to detect a change frequency, and thus a change in magnetic field strength.

81 •• [SSM] A long straight wire carries a current of 20.0 A, as shown in Figure 27-63. A rectangular coil that has two sides parallel to the straight wire has sides that are 5.00-cm long and 10.0-cm long. The side nearest to the wire is 2.00 cm from the wire. The coil carries a current of 5.00 A. (*a*) Find the force on each segment of the rectangular coil due to the current in the long straight wire. (*b*) What is the net force on the coil?

Picture the Problem Let I_1 and I_2 represent the currents of 20 A and 5.0 A, $\vec{F}_{\text{top}}$, $\vec{F}_{\text{left side}}$, $\vec{F}_{\text{bottom}}$, and $\vec{F}_{\text{right side}}$ the forces that act on the four segments of the rectangular current loop, and $\vec{B}_1$, $\vec{B}_2$, $\vec{B}_3$, and $\vec{B}_4$ the magnetic fields at these wire segments due to I_1. We'll need to take into account the fact that $\vec{B}_1$ and $\vec{B}_3$ are not constant over the segments 1 and 3 of the rectangular coil. Let the +*x* direction be to the right and the +*y* direction be upward. Then the +*z* direction is toward you (i.e., out of the page). Note that only the components of $\vec{B}_1$, $\vec{B}_2$, $\vec{B}_3$, and $\vec{B}_4$ into or out of the page contribute to the forces acting on the rectangular coil. The +*x* and +*y* directions are up the page and to the right.

(*a*) Express the force $d\vec{F}_1$ acting on a current element $I_2 d\vec{\ell}$ in the top segment of wire:

$$d\vec{F}_{\text{top}} = I_2 d\vec{\ell} \times \vec{B}_1$$

Because $I_2 d\vec{\ell} = I_2 d\ell\left(-\hat{i}\right)$ in this segment of the coil and the magnetic field due to I_1 is given by $\vec{B}_1 = \frac{\mu_0 I_1}{2\pi\,\ell}\left(-\hat{k}\right)$:

$$\vec{F}_{\text{top}} = I_2 d\ell\left(-\hat{i}\right)\times\frac{\mu_0 I_1}{2\pi\,\ell}\left(-\hat{k}\right) = -\frac{\mu_0 I_1 I_2}{2\pi}\frac{d\ell}{\ell}\hat{j}$$

Integrate $d\vec{F}_{\text{top}}$ to obtain:

$$\vec{F}_{\text{top}} = -\frac{\mu_0 I_1 I_2}{2\pi}\int_{2.0\,\text{cm}}^{7.0\,\text{cm}}\frac{d\ell}{\ell}\hat{j} = -\frac{\mu_0 I_1 I_2}{2\pi}\ln\left(\frac{7.0\text{ cm}}{2.0\text{ cm}}\right)\hat{j}$$

Substitute numerical values and evaluate $\vec{F}_{\text{top}}$:

$$\vec{F}_{\text{top}} = -\frac{\left(4\pi\times10^{-7}\ \frac{\text{N}}{\text{A}^2}\right)(20\text{ A})(5.0\text{ A})}{2\pi}\ln\left(\frac{7.0\text{ cm}}{2.0\text{ cm}}\right)\hat{j} = \boxed{-\left(2.5\times10^{-5}\text{ N}\right)\hat{j}}$$

Express the force $d\vec{F}_{\text{bottom}}$ acting on a current element $I_2 d\vec{\ell}$ in the horizontal segment of wire at the bottom of the coil:

$$d\vec{F}_{\text{bottom}} = I_2 d\vec{\ell}\times\vec{B}_3$$

Because $I_2 d\vec{\ell} = I_2 d\ell\left(\hat{i}\right)$ in this segment of the coil and the magnetic field due to I_1 is given by $\vec{B}_1 = \frac{\mu_0 I_1}{2\pi\,\ell}\left(-\hat{k}\right)$:

$$d\vec{F}_{\text{bottom}} = I_2 d\ell\hat{i}\times\frac{\mu_0 I_1}{2\pi\ell}\left(-\hat{k}\right) = \frac{\mu_0 I_1 I_2}{2\pi}\frac{d\ell}{\ell}\hat{j}$$

Integrate $d\vec{F}_{\text{bottom}}$ to obtain:

$$d\vec{F}_{\text{bottom}} = \frac{\mu_0 I_1 I_2}{2\pi}\int_{2.0\,\text{cm}}^{7.0\,\text{cm}}\frac{d\ell}{\ell}\hat{j} = \frac{\mu_0 I_1 I_2}{2\pi}\ln\left(\frac{7.0\text{ cm}}{2.0\text{ cm}}\right)\hat{j}$$

Substitute numerical values and evaluate $\vec{F}_{\text{bottom}}$:

$$\vec{F}_{\text{bottom}} = \frac{\left(4\pi\times10^{-7}\ \frac{\text{N}}{\text{A}^2}\right)(20\text{ A})(5.0\text{ A})}{2\pi}\ln\left(\frac{7.0\text{ cm}}{2.0\text{ cm}}\right)\hat{j} = \boxed{\left(2.5\times10^{-5}\text{ N}\right)\hat{j}}$$

Express the forces $\vec{F}_{\text{left side}}$ and $\vec{F}_{\text{right side}}$ in terms of I_2 and $\vec{B}_2$ and $\vec{B}_4$:

$$\vec{F}_{\text{left side}} = I_2\vec{\ell}_2\times\vec{B}_2$$

and

$$\vec{F}_{\text{right side}} = I_2\vec{\ell}_4\times\vec{B}_4$$

Express $\vec{B}_2$ and $\vec{B}_4$:

$$\vec{B}_2 = -\frac{\mu_0}{4\pi}\frac{2I_1}{R_1}\hat{k} \text{ and } \vec{B}_4 = -\frac{\mu_0}{4\pi}\frac{2I_1}{R_4}\hat{k}$$

Substitute for $\vec{B}_2$ and $\vec{B}_4$ to obtain:

$$\vec{F}_{\text{left side}} = -I_2\ell_2\hat{j}\times\left(-\frac{\mu_0}{4\pi}\frac{2I_1}{R_1}\hat{k}\right) = \frac{\mu_0\ell_2 I_1 I_2}{2\pi R_2}\hat{i}$$

and

$$\vec{F}_{\text{right side}} = I_2\ell_4\hat{j}\times\left(-\frac{\mu_0}{4\pi}\frac{2I_1}{R_4}\hat{k}\right) = -\frac{\mu_0\ell_4 I_1 I_2}{2\pi R_4}\hat{i}$$

Substitute numerical values and evaluate $\vec{F}_{\text{left side}}$ and $\vec{F}_{\text{right side}}$:

$$\vec{F}_{\text{left side}} = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(0.100\,\text{m})(20.0\,\text{A})(5.00\,\text{A})}{2\pi(0.0200\,\text{m})}\hat{i} = \boxed{\left(1.0\times10^{-4}\ \text{N}\right)\hat{i}}$$

and

$$\vec{F}_{\text{right side}} = -\frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(0.100\,\text{m})(20.0\,\text{A})(5.00\,\text{A})}{2\pi(0.0700\,\text{m})}\hat{i} = \boxed{\left(-0.29\times10^{-4}\ \text{N}\right)\hat{i}}$$

(*b*) Express the net force acting on the coil:

$$\vec{F}_{\text{net}} = \vec{F}_{\text{top}} + \vec{F}_{\text{left side}} + \vec{F}_{\text{bottom}} + \vec{F}_{\text{right side}}$$

Substitute for $\vec{F}_{\text{top}}$, $\vec{F}_{\text{left side}}$, $\vec{F}_{\text{bottom}}$, and $\vec{F}_{\text{right side}}$ and simplify to obtain:

$$\begin{aligned}\vec{F}_{\text{net}} &= \left(-2.5\times10^{-5}\ \text{N}\right)\hat{j} + \left(1.0\times10^{-4}\ \text{N}\right)\hat{i} + \left(2.5\times10^{-5}\ \text{N}\right)\hat{j} + \left(-0.29\times10^{-4}\ \text{N}\right)\hat{i}\\ &= \boxed{\left(0.71\times10^{-4}\ \text{N}\right)\hat{i}}\end{aligned}$$

82 •• The closed loop shown in Figure 27-64 carries a current of 8.0 A in the counterclockwise direction. The radius of the outer arc is 0.60 m and that of the inner arc is 0.40 m. Find the magnetic field at point *P*.

Picture the Problem Let out of the page be the positive *x* direction and the numerals 40 and 60 refer to the circular arcs whose radii are 40 cm and 60 cm. Because point *P* is on the line connecting the straight segments of the conductor, these segments do not contribute to the magnetic field at *P*. Hence the resultant magnetic field at *P* will be the sum of the magnetic fields due to the current in the two circular arcs and we can use the expression for the magnetic field at the center of a current loop to find $\vec{B}_P$.

Express the resultant magnetic field at P:

$$\vec{B}_P = \vec{B}_{40} + \vec{B}_{60} \qquad (1)$$

Express the magnetic field strength at the center of a current loop:

$$B = \frac{\mu_0 I}{2R}$$

where R is the radius of the loop.

Express the magnetic field strength at the center of one-sixth of a current loop:

$$B = \frac{1}{6}\frac{\mu_0 I}{2R} = \frac{\mu_0 I}{12R}$$

Express $\vec{B}_{40}$ and $\vec{B}_{60}$:

$$\vec{B}_{40} = -\frac{\mu_0 I}{12R_{40}}\hat{\boldsymbol{i}} \text{ and } \vec{B}_{60} = \frac{\mu_0 I}{12R_{60}}\hat{\boldsymbol{i}}$$

Substitute for $\vec{B}_{40}$ and $\vec{B}_{60}$ in equation (1) and simplify to obtain:

$$\vec{B}_P = -\frac{\mu_0 I}{12R_{40}}\hat{\boldsymbol{i}} + \frac{\mu_0 I}{12R_{60}}\hat{\boldsymbol{i}} = \frac{\mu_0 I}{12}\left(\frac{1}{R_{60}} - \frac{1}{R_{40}}\right)\hat{\boldsymbol{i}}$$

Substitute numerical values and evaluate $\vec{B}_P$:

$$\vec{B}_P = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(8.0\ \text{A})}{12}\left(\frac{1}{0.60\ \text{m}} - \frac{1}{0.40\ \text{m}}\right)\hat{\boldsymbol{i}} = (-0.70\ \mu\text{T})\hat{\boldsymbol{i}}$$

or

$$B_P = \boxed{0.70\ \mu\text{T into the page}}$$

83 •• A closed circuit consists of two semicircles of radii 40 cm and 20 cm that are connected by straight segments, as shown in Figure 27-65. A current of 3.0 A exists in this circuit and has a clockwise direction. Find the magnetic field at point P.

Picture the Problem Let the $+x$ direction be into the page and the numerals 20 and 40 refer to the circular arcs whose radii are 20 cm and 40 cm. Because point P is on the line connecting the straight segments of the conductor, these segments do not contribute to the magnetic field at P and the resultant field at P is the sum of the fields due to the two semicircular current loops.

Express the resultant magnetic field at P:

$$\vec{B}_P = \vec{B}_{20} + \vec{B}_{40} \qquad (1)$$

Express the magnetic field strength at the center of a circular current loop:

$$B = \frac{\mu_0 I}{2R}$$

where R is the radius of the loop.

Express the magnetic field strength at the center of half a circular current loop:

$$B = \frac{1}{2}\frac{\mu_0 I}{2R} = \frac{\mu_0 I}{4R}$$

Express $\vec{B}_{20}$ and $\vec{B}_{40}$:

$$\vec{B}_{20} = \frac{\mu_0 I}{4R_{20}}\hat{i} \text{ and } \vec{B}_{40} = \frac{\mu_0 I}{4R_{40}}\hat{i}$$

Substitute for $\vec{B}_{20}$ and $\vec{B}_{40}$ in equation (1) and simplify to obtain:

$$\vec{B}_P = \frac{\mu_0 I}{4R_{20}}\hat{i} + \frac{\mu_0 I}{4R_{40}}\hat{i} = \frac{\mu_0 I}{4}\left(\frac{1}{R_{20}} + \frac{1}{R_{40}}\right)\hat{i}$$

Substitute numerical values and evaluate B_P:

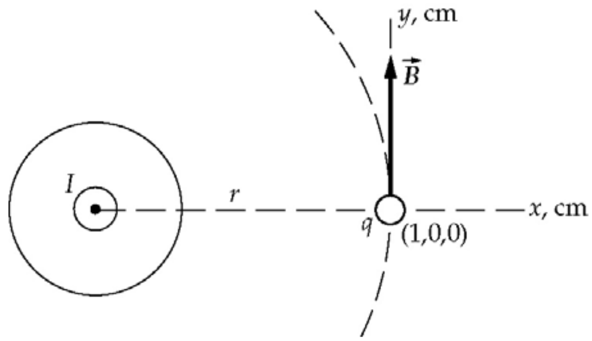
$$\vec{B}_P = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)(3.0\ \text{A})}{4}\left(\frac{1}{0.20\ \text{m}} + \frac{1}{0.40\ \text{m}}\right)\hat{i} = \boxed{(7.1\ \mu\text{T})\hat{i}}$$

or

$$B_P = \boxed{7.1\ \mu\text{T into the page}}$$

84 •• A very long straight wire carries a current of 20.0 A. An electron outside the wire is 1.00 cm from the central axis of the wire is moving with a speed of 5.00×10^6 m/s. Find the force on the electron when it moves (*a*) directly away from the wire, (*b*) parallel to the wire in the direction of the current, and (*c*) perpendicular to the central axis of wire and tangent to a circle that is coaxial with the wire.

Picture the Problem Chose the coordinate system shown below. Then the current is in the +z direction. Assume that the electron is at (1.00 cm, 0, 0). We can use $\vec{F} = q\vec{v}\times\vec{B}$ to relate the magnetic force on the electron to $\vec{v}$ and $\vec{B}$ and $\vec{B} = \frac{\mu_0}{4\pi}\frac{2I}{r}\hat{j}$ to express the magnetic field at the location of the electron. We'll need to express $\vec{v}$ for each of the three situations described in the problem in order to evaluate $\vec{F} = q\vec{v}\times\vec{B}$.



Express the magnetic force acting on the electron:

$$\vec{F} = q\vec{v} \times \vec{B}$$

Express the magnetic field due to the current in the wire as a function of distance from the wire:

$$\vec{B} = \frac{\mu_0}{4\pi}\frac{2I}{r}\hat{j}$$

Substitute for $\vec{B}$ and simplifying yields:

$$\vec{F} = q\vec{v} \times \frac{\mu_0}{4\pi}\frac{2I}{r}\hat{j} = \frac{2q\mu_0 I}{4\pi r}\left(\vec{v} \times \hat{j}\right) \quad (1)$$

(*a*) Express the velocity of the electron when it moves directly away from the wire:

$$\vec{v} = v\hat{i}$$

Substitute for $\vec{v}$ in equation (1) and simplify to obtain:

$$\vec{F} = \frac{2q\mu_0 I}{4\pi r}\left(v\hat{i} \times \hat{j}\right) = \frac{2q\mu_0 Iv}{4\pi r}\hat{k}$$

Substitute numerical values and evaluate $\vec{F}$:

$$\vec{F} = \frac{2\left(4\pi \times 10^{-7}\ \text{N/A}^2\right)\left(-1.602 \times 10^{-19}\ \text{C}\right)\left(5.00 \times 10^{6}\ \text{m/s}\right)\left(20.0\ \text{A}\right)\hat{k}}{4\pi\left(0.0100\ \text{m}\right)}$$
$$= \left(-3.20 \times 10^{-16}\ \text{N}\right)\hat{k}$$

and

$$F = \boxed{3.20 \times 10^{-16}\ \text{N into the page}}$$

(*b*) Express $\vec{v}$ when the electron is traveling parallel to the wire in the direction of the current:

$$\vec{v} = v\hat{k}$$

Substitute in equation (1) to obtain:

$$\vec{F} = \frac{2q\mu_0 I}{4\pi r}\left(v\hat{k} \times \hat{j}\right) = -\frac{2q\mu_0 Iv}{4\pi r}\hat{i}$$

Substitute numerical values and evaluate $\vec{F}$:

$$\vec{F} = -\frac{2(4\pi\times10^{-7}\ \mathrm{N/A^2})(-1.602\times10^{-19}\ \mathrm{C})(5.00\times10^{6}\ \mathrm{m/s})(20.0\,\mathrm{A})\hat{\boldsymbol{i}}}{4\pi(0.0100\,\mathrm{m})}$$
$$= (3.20\times10^{-16}\ \mathrm{N})\hat{\boldsymbol{i}}$$

and

$$F = \boxed{3.20\times10^{-16}\ \text{N toward the right}}$$

(*c*) Express $\vec{v}$ when the electron is traveling perpendicular to the wire and tangent to a circle around the wire:

$$\vec{v} = v\hat{\boldsymbol{j}}$$

Substitute for $\vec{v}$ in equation (1) and simplify to obtain:

$$\vec{F} = \frac{2q\mu_0 I}{4\pi r}\left(v\hat{\boldsymbol{j}}\times\hat{\boldsymbol{j}}\right) = \boxed{0}$$

85 •• A current of 5.00 A is uniformly distributed over the cross section of a long straight wire of radius $R_o = 2.55$ mm. Using a **spreadsheet** program, graph the magnetic field strength as a function of R, the distance from the central axis of the wire, for $0 \le R \le 10R_0$.

Picture the Problem We can apply Ampère's law to derive expressions for the magnetic field strength as a function of the distance from the center of the wire.

Apply Ampère's law to a closed circular path of radius $r \le R_0$ to obtain:

$$B_{r\le R_0}(2\pi r) = \mu_0 I_C$$

Because the current is uniformly distributed over the cross section of the wire:

$$\frac{I_C}{\pi r^2} = \frac{I}{\pi R_0^2} \Rightarrow I_C = \frac{r^2}{R_0^2}I$$

Substitute for I_C to obtain:

$$B_{r\le R_0}(2\pi r) = \frac{\mu_0 r^2 I}{R_0^2}$$

Solving for $B_{r\le R_0}$ yields:

$$B_{r\le R_0} = \frac{\mu_0 r I}{2\pi R_0^2} = \frac{\mu_0}{4\pi}\frac{2I}{R_0^2}r \qquad (1)$$

Apply Ampère's law to a closed circular path of radius $r > R_0$ to obtain:

$$B_{r>R_0}(2\pi r) = \mu_0 I_C = \mu_0 I$$

Solving for $B_{r>R_0}$ yields:

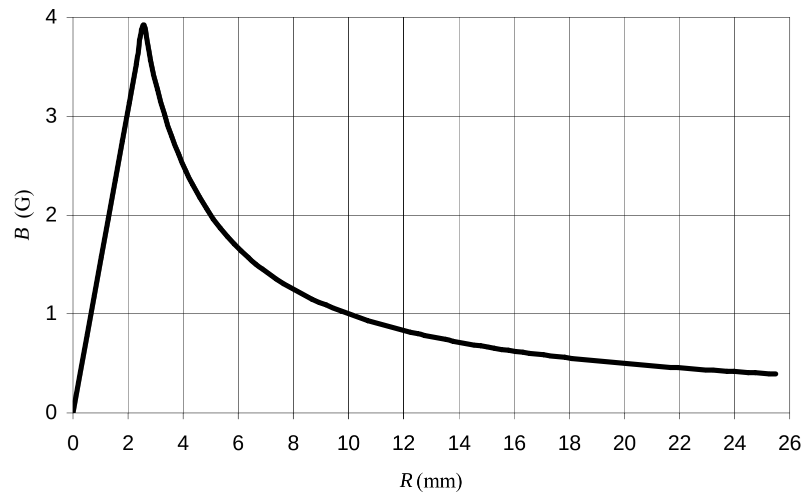
$$B_{r>r_0} = \frac{\mu_0}{4\pi}\frac{2I}{r} \tag{2}$$

The spreadsheet program to calculate B as a function of r in the interval $0 \le r \le 10R_0$ follows. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	1.00E−07	$\frac{\mu_0}{4\pi}$
B2	5.00	I
B3	2.55E−03	R_0
C6	10^4*$B$1*2*$B$2*A6/$B$3^2	$\frac{\mu_0}{4\pi}\frac{2I}{R_0^2}r$
C17	10^4*$B$1*2*$B$2*A6/A17	$\frac{\mu_0}{4\pi}\frac{2I}{r}$

	A	B	C
1	$\mu/4\pi$=	1.00E−07	N/A^2
2	I=	5	A
3	R_0=	2.55E−03	m
4			
5	R (m)	R (mm)	B (T)
6	0.00E+00	0.00E+00	0.00E+00
7	2.55E−04	2.55E−01	3.92E−01
8	5.10E−04	5.10E−01	7.84E−01
9	7.65E−04	7.65E−01	1.18E+00
10	1.02E−03	1.02E+00	1.57E+00
102	2.45E−02	2.45E+01	4.08E−01
103	2.47E−02	2.47E+01	4.04E−01
104	2.50E−02	2.50E+01	4.00E−01
105	2.52E−02	2.52E+01	3.96E−01
106	2.55E−02	2.55E+01	3.92E−01

A graph of B as a function of r follows.



86 •• A 50-turn coil of radius 10.0 cm carries a current of 4.00 A and a concentric 20-turn coil of radius 0.500 cm carries a current of 1.00 A. The planes of the two coils are perpendicular. Find the magnitude of the torque exerted by the large coil on the small coil. (Neglect any variation in magnetic field due to the current in the large coil over the region occupied by the small coil.)

Picture the Problem We can use $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$ to find the torque exerted on the small coil (magnetic moment = $\vec{\boldsymbol{\mu}}$) by the magnetic field $\vec{\boldsymbol{B}}$ due to the current in the large coil.

Relate the torque exerted by the large coil on the small coil to the magnetic moment $\vec{\boldsymbol{\mu}}$ of the small coil and the magnetic field $\vec{\boldsymbol{B}}$ due to the current in the large coil:

$$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\boldsymbol{B}}$$

or, because the planes of the two coils are perpendicular, $\tau = \mu B$

Express the magnetic moment of the small coil:

$$\mu = NIA$$

where I is the current in the coil, N is the number of turns in the coil, and A is the cross-sectional area of the coil.

Express the magnetic field at the center of the large coil:

$B = \dfrac{N'\mu_0 I'}{2R}$ where I' is the current in the large coil, N' is the number of turns in the coil, and R is its radius.

Substitute for B and μ in the expression for τ to obtain:

$$\tau = \frac{NN'II'A\mu_0}{2R}$$

Substitute numerical values and evaluate τ:

$$\tau = \frac{(50)(20)(4.00\,\text{A})(1.00\,\text{A})\pi(0.500\,\text{cm})^2\left(4\pi\times10^{-7}\ \text{N/A}^2\right)}{2(10.0\,\text{cm})} = \boxed{1.97\,\mu\text{N}\cdot\text{m}}$$

87 •• The magnetic needle of a compass is a uniform rod with a length of 3.00 cm, a radius of 0.850 mm, and a density of 7.96×10^3 kg/m^3. The needle is free to rotate in a horizontal plane, where the horizontal component of Earth's magnetic field is 0.600 G. When disturbed slightly, the compass executes simple harmonic motion about its midpoint with a frequency of 1.40 Hz. (*a*) What is the magnetic dipole moment of the needle? (*b*) What is the magnetization of the needle? (*c*) What is the amperian current on the surface of the needle?

Picture the Problem (*a*) We can solve the equation for the frequency f of the compass needle for the magnetic dipole moment of the needle. In Parts (*b*) and (*c*) we can use their definitions to find the magnetization M and the amperian current I_{amperian}.

(*a*) The frequency of the compass needle is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{\mu B}{I}} \Rightarrow \mu = \frac{4\pi^2 f^2 I}{B}$$

where I is the moment of inertia of the needle.

The moment of inertia of the needle is:

$$I = \tfrac{1}{12}mL^2 = \tfrac{1}{12}\rho VL^2 = \tfrac{1}{12}\rho\pi r^2 L^3$$

Substitute for I to obtain:

$$\mu = \frac{\pi^3 f^2 \rho r^2 L^3}{3B}$$

Substitute numerical values and evaluate μ:

$$\mu = \frac{\pi^3\left(1.40\,\text{s}^{-1}\right)^2\left(7.96\times10^3\ \text{kg/m}^3\right)\left(0.850\times10^{-3}\ \text{m}\right)^2(0.0300\,\text{m})^3}{3\left(0.600\times10^{-4}\ \text{T}\right)} = \boxed{5.24\times10^{-2}\ \text{A}\cdot\text{m}^2}$$

(*b*) Use its definition to express the magnetization M:

$$M = \frac{\mu}{V}$$

Substitute to obtain:

$$M=\frac{\mu}{V}=\frac{\pi^3 f^2\rho r^2L^3}{3BV}=\frac{\pi^2 f^2\rho L^2}{3B}$$

Substitute numerical values and evaluate M:

$$M=\frac{\pi^2\left(1.40\,\text{s}^{-1}\right)^2\left(7.96\times10^3\ \text{kg/m}^3\right)\left(0.0300\,\text{m}\right)^2}{3\left(0.600\times10^{-4}\ \text{T}\right)}=\boxed{7.70\times10^5\ \text{A/m}}$$

(*c*) The amperian current on the surface of the needle is:

$$I_{\text{amperian}}=ML=\left(7.70\times10^5\ \text{A/m}\right)\left(0.0300\,\text{m}\right)=\boxed{23.1\text{kA}}$$

88 •• A relatively inexpensive ammeter, called a *tangent galvanometer*, can be made using Earth's magnetic field. A plane circular coil that has N turns and a radius R is oriented so the magnetic field B_c it produces in the center of the coil is either east or west. A compass is placed at the center of the coil. When there is no current in the coil, assume the compass needle points due north. When there is a current in the coil (I), the compass needle points in the direction of the resultant magnetic field at an angle θ to the north. Show that the current I is related to θ and to the horizontal component of Earth's magnetic field B_e by $I=\dfrac{2RB_e}{\mu_0 N}\tan\theta$.

Picture the Problem Note that B_e and B_c are perpendicular to each other and that the resultant magnetic field is at an angle θ with north. We can use trigonometry to relate B_c and B_e and express B_c in terms of the geometry of the coil and the current flowing in it.

Express B_c in terms of B_e:

$$B_c=B_e\tan\theta$$

where θ is the angle of the resultant field from north.

Express the field B_c due to the current in the coil:

$$B_c=\frac{N\mu_0 I}{2R}$$

where N is the number of turns.

Substitute for B_c to obtain:

$$\frac{N\mu_0 I}{2R}=B_e\tan\theta\Rightarrow I=\boxed{\frac{2RB_e}{\mu_0 N}\tan\theta}$$

89 •• Earth's magnetic field is about 0.600 G at the magnetic poles, and is pointed vertically downward at the magnetic pole in the northern hemisphere. If the magnetic field were due to an electric current circulating in a loop at the radius of the inner iron core of Earth (approximately 1300 km), (*a*) what would be the magnitude of the current required? (*b*) What direction would this current have—the same as Earth's spin, or opposite? Explain your answer.

Picture the Problem The current required can be found by solving the equation for the magnetic field on the axis of a current loop for the current in the loop. We can use the right-hand rule to determine the direction of this current.

(*a*) The magnetic field on the axis of a current loop is given by:

$$B_x = \frac{\mu_0}{4\pi}\frac{2\pi R^2 I}{\left(x^2 + R^2\right)^{3/2}}$$

Solving for I yields:

$$I = \frac{4\pi\left(x^2 + R^2\right)^{3/2} B_x}{2\pi\mu_0 R^2}$$

Substitute numerical values and evaluate I:

$$I = \frac{4\pi\left((6370\,\text{km})^2 + (1300\,\text{km})^2\right)^{3/2}\left(0.600\,\text{G}\times\frac{1\,\text{T}}{10^4\,\text{G}}\right)}{2\pi\left(4\pi\times10^{-7}\,\frac{\text{N}}{\text{A}^2}\right)(1300\,\text{km})^2} = \boxed{15.5\,\text{GA}}$$

(*b*) Because Earth's magnetic field points down at the north pole, application of the right-hand rule indicates that the current is opposite the spin direction of Earth.

90 •• A long, narrow bar magnet has its magnetic moment $\vec{\boldsymbol{\mu}}$ parallel to its long axis and is suspended at its center—in essence becoming a frictionless compass needle. When the magnet is placed in a magnetic field $\vec{\boldsymbol{B}}$, it lines up with the field. If it is displaced by a small angle and released, show that the magnet will oscillate about its equilibrium position with frequency given by $\frac{1}{2\pi}\sqrt{\frac{\mu B}{I}}$, where I is the moment of inertia about the point of suspension.

Picture the Problem We can apply Newton's second law for rotational motion to obtain the differential equation of motion of the bar magnet. While this equation is not linear, we can use a small-angle approximation to render it linear and obtain an expression for the square of the angular frequency that we can solve for the frequency f of the motion.

Apply Newton's second law to the bar magnet to obtain the differential equation of motion for the magnet:

$$-\mu B\sin\theta = I\frac{d^2\theta}{dt^2}$$

where I is the moment of inertia of the magnet about an axis through its point of suspension.

For small displacements from equilibrium ($\theta << 1$):

$$-\mu B\theta \approx I\frac{d^2\theta}{dt^2}$$

Rewrite the differential equation as:

$$I\frac{d^2\theta}{dt^2} + \mu B\theta = 0$$

or

$$\frac{d^2\theta}{dt^2} + \frac{\mu B}{I}\theta = 0$$

Because the coefficient of the linear term is the square of the angular frequency, we have:

$$\omega^2 = \frac{\mu B}{I} \Rightarrow \omega = \sqrt{\frac{\mu B}{I}}$$

Because $\omega = 2\pi f$:

$$2\pi f = \sqrt{\frac{\mu B}{I}} \Rightarrow f = \boxed{\frac{1}{2\pi}\sqrt{\frac{\mu B}{I}}}$$

91 •• An infinitely long straight wire is bent, as shown in Figure 27-66. The circular portion has a radius of 10.0 cm and its center a distance r from the straight part. Find r so that the magnetic field at the region occupied by the center of the circular portion is zero.

Picture the Problem Let the +x direction be out of the page. We can use the expressions for the magnetic fields due to an infinite straight line and a circular loop to express the net magnetic field at the center of the circular loop. We can set this net field to zero and solve for r.

Express the net magnetic field at the center of circular loop:

$$\vec{B} = \vec{B}_{\text{loop}} + \vec{B}_{\text{line}} \qquad (1)$$

Letting R represent the radius of the loop, express $\vec{B}_{\text{loop}}$:

$$\vec{B}_{\text{loop}} = -\frac{\mu_0 I}{2R}\hat{i}$$

Express the magnetic field due to the current in the infinite straight line:

$$\vec{B}_{\text{line}} = \frac{\mu_0 I}{2\pi r}\hat{i}$$

Substitute for $\vec{B}_{\text{loop}}$ and $\vec{B}_{\text{line}}$ in equation (1) and simplify to obtain:

$$\vec{B} = -\frac{\mu_0 I}{2R}\hat{i} + \frac{\mu_0 I}{2\pi r}\hat{i} = \left(-\frac{\mu_0 I}{2R} + \frac{\mu_0 I}{2\pi r}\right)\hat{i}$$

If $\vec{B} = 0$, then:

$$-\frac{\mu_0 I}{2R} + \frac{\mu_0 I}{2\pi r} = 0 \Rightarrow -\frac{1}{R} + \frac{1}{\pi r} = 0$$

Solving for r yields:

$$r = \frac{10.0\,\text{cm}}{\pi} = \boxed{3.18\,\text{cm}}$$

92 •• (*a*) Find the magnetic field strength point *P* on the perpendicular bisector of a wire segment carrying current *I*, as shown in Figure 27-67. (*b*) Use your result from Part (*a*) to find the magnetic field strength at the center of a regular polygon of *N* sides. (*c*) Show that when *N* is very large, your result approaches that for the magnetic field strength at the center of a circle.

Picture the Problem (*a*) We can use the expression for *B* due to a straight wire segment, to find the magnetic field strength at *P*. Note that the current in the wires whose lines contain point *P* do not contribute to the magnetic field strength at point *P*. In Part (*b*) we can use our result from (*a*), together with the value for θ when the polygon has *N* sides, to obtain an expression for *B* at the center of a polygon of *N* sides. (*c*) Letting *N* grow without bound will yield the equation for the magnetic field strength at the center of a circle.

(*a*) Express the magnetic field strength at *P* due to the straight wire segment:

$$B_P = \frac{\mu_0}{4\pi}\frac{I}{R}\left(\sin\theta_1 + \sin\theta_2\right)$$

Because $\theta_1 = \theta_2 = \theta$:

$$B_P = \frac{\mu_0}{4\pi}\frac{I}{R}\left(2\sin\theta\right) = \left(\frac{\mu_0}{2\pi}\frac{I}{R}\right)\sin\theta$$

Refer to the figure to obtain:

$$\sin\theta = \frac{a}{\sqrt{a^2 + R^2}}$$

Substituting for $\sin\theta$ in the expression for B_P yields:

$$B_P = \boxed{\frac{\mu_0 a I}{2\pi R\sqrt{a^2 + R^2}}}$$

(*b*) θ for an *N*-sided polygon is given by:

$$\theta = \frac{\pi}{N}$$

Because each side of the polygon contributes to B an amount equal to that obtained in (a):

$$B = \boxed{\left(\frac{N\mu_0 I}{2\pi R}\right)\sin\left(\frac{\pi}{N}\right)},\ N = 3, 4, \ldots K$$

(c) For large N, π/N is small, so $\sin\left(\frac{\pi}{N}\right) \approx \frac{\pi}{N}$. Hence:

$$B_\infty = \text{Limit}_{N\to\infty} N\frac{\mu_0 I}{2\pi R}\sin\left(\frac{\pi}{N}\right)$$

$$= \frac{\mu_0 I}{2\pi R}\text{Limit}_{N\to\infty} N\frac{\pi}{N} = \boxed{\frac{\mu_0 I}{2R}}$$

the expression for the magnetic field strength at the center of a current-carrying circular loop.

93 •• The current in a long cylindrical conductor of radius 10 cm varies with distance from the axis of the cylinder according to the relation $I(r) = (50\ \text{A/m})r$. Find the magnetic field at the following perpendicular distances from the wire's central axis (a) 5.0 cm, (b) 10 cm, and (c) 20 cm.

Picture the Problem We can use Ampère's law to derive expressions for $B(r)$ for $r \le R$ and $r > R$ that we can evaluate for the given distances from the center of the cylindrical conductor.

Apply Ampère's law to a closed circular path a distance $r \le R$ from the center of the cylindrical conductor to obtain:

$$\oint_C \vec{B}\cdot d\vec{\ell} = B(r)(2\pi r) = \mu_0 I_C = \mu_0 I(r)$$

Solve for $B(r)$ to obtain:

$$B(r) = \frac{\mu_0 I(r)}{2\pi r}$$

Substitute for $I(r)$:

$$B(r) = \frac{\mu_0(50\ \text{A/m})r}{2\pi r} = \frac{\mu_0(50\ \text{A/m})}{2\pi}$$

(a) and (b) Noting that B is independent of r, substitute numerical values and evaluate B(5.0 cm) and B(10 cm):

$$B(5.0\,\text{cm}) = B(10\,\text{cm}) = \frac{(4\pi\times10^{-7}\ \text{N/A}^2)(50\,\text{A/m})}{2\pi} = \boxed{10\,\mu\text{T}}$$

(*c*) Apply Ampère's law to a closed circular path a distance $r > R$ from the center of the cylindrical conductor to obtain:

$$\oint_C \vec{B}\cdot d\vec{\ell} = B(r)(2\pi r) = \mu_0 I_C = \mu_0 I(R)$$

Solving for $B(r)$ yields:

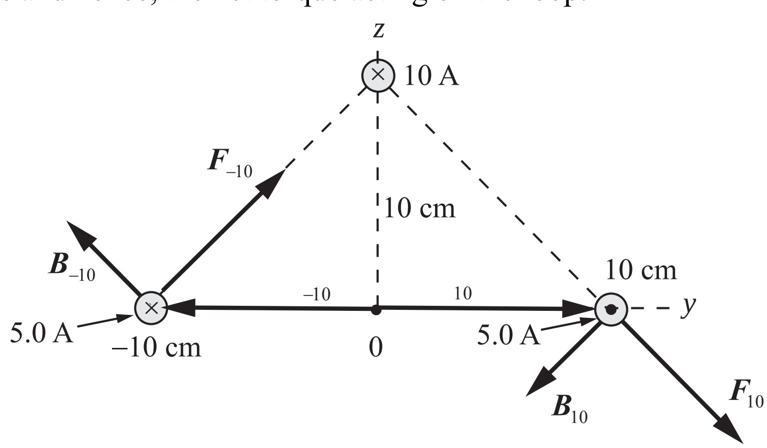
$$B(r) = \frac{\mu_0 I(R)}{2\pi r}$$

Substitute numerical values and evaluate $B(20\text{ cm})$:

$$B(20\,\text{cm}) = \frac{(4\pi\times10^{-7}\ \text{N/A}^2)(50\,\text{A/m})(0.10\,\text{m})}{2\pi(0.20\,\text{m})} = \boxed{5.0\,\mu\text{T}}$$

94 •• Figure 27- 68 shows a square loop that has 20-cm long sides and is in the $z = 0$ plane with its center at the origin. The loop carries a current of 5.0 A. An infinitely long wire that is parallel to the *x* axis and carries a current of 10 A intersects the *z* axis at $z = 10$ cm. The directions of the currents are shown in the figure. (*a*) Find the net torque on the loop. (*b*) Find the net force on the loop.

Picture the Problem The field $\vec{B}$ due to the 10-A current is in the *yz* plane. The net force on the wires of the square in the *y* direction cancel and do not contribute to a net torque or force. We can use $\vec{\tau} = \vec{\ell}\times\vec{F}$, $\vec{F} = I\vec{\ell}\times\vec{B}$, and the expression for the magnetic field due to a long straight wire to express the torque acting on each of the wires and hence, the net torque acting on the loop.



(*a*) The net torque about the *x* axis is the sum of the torques due to the forces $\vec{F}_{10}$ and $\vec{F}_{-10}$:

$$\vec{\tau}_{\text{net}} = \vec{\tau}_{10} + \vec{\tau}_{-10}$$

Substituting for $\vec{\boldsymbol{\tau}}_{10}$ and $\vec{\boldsymbol{\tau}}_{-10}$ yields:

$$\vec{\boldsymbol{\tau}}_{\text{net}} = \vec{\ell}_{10} \times \vec{\boldsymbol{F}}_{10} + \vec{\ell}_{-10} \times \vec{\boldsymbol{F}}_{-10}$$

where the subscripts refer to the positions of the current-carrying wires.

The forces acting on the wires are given by:

$$\vec{\boldsymbol{F}}_{10} = \left(I\vec{\ell}\right)_{10} \times \vec{\boldsymbol{B}}_{10}$$

and

$$\vec{\boldsymbol{F}}_{-10} = \left(I\vec{\ell}\right)_{-10} \times \vec{\boldsymbol{B}}_{-10}$$

Substitute for $\vec{\boldsymbol{F}}_{10}$ and $\vec{\boldsymbol{F}}_{-10}$ to obtain:

$$\vec{\boldsymbol{\tau}}_{\text{net}} = \vec{\ell}_{10} \times \left[\left(I\vec{\ell}\right)_{10} \times \vec{\boldsymbol{B}}_{10}\right] + \vec{\ell}_{-10} \times \left[\left(I\vec{\ell}\right)_{-10} \times \vec{\boldsymbol{B}}_{-10}\right] \qquad (1)$$

The lever arms for the forces acting on the wires at $y = 10$ cm and $y = -10$ cm are:

$$\vec{\ell}_{10} = (0.10\text{ m})\hat{j} \text{ and } \vec{\ell}_{-10} = -(0.10\text{ m})\hat{j}$$

The magnetic field at the wire at $y = 10$ cm is given by:

$$\vec{\boldsymbol{B}}_{10} = \frac{\mu_0}{4\pi}\frac{2I}{R}\frac{1}{\sqrt{2}}\left(-\hat{\boldsymbol{j}} - \hat{\boldsymbol{k}}\right)$$

where

$$R = \sqrt{(0.10\text{m})^2 + (0.10\text{m})^2} = 0.141\text{m}.$$

Substitute numerical values and evaluate $\vec{\boldsymbol{B}}_{10}$:

$$\vec{\boldsymbol{B}}_{10} = \frac{4\pi \times 10^{-7}\text{ N/A}^2}{4\pi\sqrt{2}}\frac{2(10\text{ A})}{0.141\text{m}}\left(-\hat{\boldsymbol{j}} - \hat{\boldsymbol{k}}\right) = (10.0\,\mu\text{T})\left(-\hat{\boldsymbol{j}} - \hat{\boldsymbol{k}}\right)$$

Proceed similarly to obtain:

$$\vec{\boldsymbol{B}}_{-10} = (10.0\,\mu\text{T})\left(-\hat{\boldsymbol{j}} + \hat{\boldsymbol{k}}\right)$$

Substitute in equation (1) and simplify to obtain:

$$\begin{aligned}\vec{\boldsymbol{\tau}}_{\text{net}} &= (0.10\text{ m})\hat{\boldsymbol{j}} \times \left[(5.0\text{ A})(0.20\text{ m})\hat{\boldsymbol{i}} \times (10.0\,\mu\text{T})\left(-\hat{\boldsymbol{j}} - \hat{\boldsymbol{k}}\right)\right] \\ &\quad - (0.10\text{ m})\hat{\boldsymbol{j}} \times \left[(5.0\text{ A})(0.20\text{ m})\left(-\hat{\boldsymbol{i}}\right) \times (10.0\,\mu\text{T})\left(-\hat{\boldsymbol{j}} + \hat{\boldsymbol{k}}\right)\right] \\ &= \boxed{-(2.0\,\mu\text{N}\cdot\text{m})\hat{\boldsymbol{i}}}\end{aligned}$$

(*b*) The net force acting on the loop is the sum of the forces acting on its four sides:

$$\vec{\boldsymbol{F}}_{\text{net}} = \vec{\boldsymbol{F}}_{10} + \vec{\boldsymbol{F}}_{-10} \qquad (2)$$

Evaluate $\vec{F}_{10}$ to obtain:

$$\begin{aligned}\vec{F}_{10} &= \left(I\vec{\ell}\right)_{10} \times \vec{B}_{10} = (5.0\,\text{A})(0.20\,\text{m})\hat{i} \times (10.0\,\mu\text{T})\left(-\hat{j} - \hat{k}\right) \\ &= (10\,\mu\text{N})\left[\hat{i} \times \left(-\hat{j} - \hat{k}\right)\right] \\ &= (10\,\mu\text{N})\left(-\hat{k} + \hat{j}\right)\end{aligned}$$

Evaluating $\vec{F}_{-10}$ yields:

$$\begin{aligned}\vec{F}_{-10} &= \left(I\vec{\ell}\right)_{-10} \times \vec{B}_{-10} = (5.0\,\text{A})(-0.20\,\text{m})\hat{i} \times (10.0\,\mu\text{T})\left(-\hat{j} + \hat{k}\right) \\ &= (-10\,\mu\text{N})\left[\hat{i} \times \left(-\hat{j} + \hat{k}\right)\right] \\ &= (10\,\mu\text{N})\left(\hat{k} + \hat{j}\right)\end{aligned}$$

Substitute for $\vec{F}_{10}$ and $\vec{F}_{-10}$ in equation (2) and simplify to obtain:

$$\vec{F}_{\text{net}} = (10\,\mu\text{N})\left(-\hat{k} + \hat{j}\right) + (10\,\mu\text{N})\left(\hat{k} + \hat{j}\right) = \boxed{(20\,\mu\text{N})\hat{j}}$$

95 •• [SSM] A current balance is constructed in the following way: A straight 10.0-cm-long section of wire is placed on top of the pan of an electronic balance (Figure 27-69). This section of wire is connected in series with a power supply and a long straight horizontal section of wire that is parallel to it and positioned directly above it. The distance between the central axes of the two wires is 2.00 cm. The power supply provides a current in the wires. When the power supply is switched on, the reading on the balance increases by 5.00 mg. What is the current in the wire?

Picture the Problem The force acting on the lower wire is given by $F_{\text{lower wire}} = I\ell B$, where I is the current in the lower wire, ℓ is the length of the wire on the balance, and B is the magnetic field strength at the location of the lower wire due to the current in the upper wire. We can apply Ampere's law to find B at the location of the wire on the pan of the balance.

The force experienced by the lower wire is given by:

$$F_{\text{lower wire}} = I\ell B$$

Apply Ampere's law to a closed circular path of radius r centered on the upper wire to obtain:

$$B(2\pi r) = \mu_0 I_C = \mu_0 I \Rightarrow B = \frac{\mu_0 I}{2\pi r}$$

Substituting for B in the expression for the force on the lower wire and simplifying yields:

$$F_{\text{lower wire}} = I\ell\left(\frac{\mu_0 I}{2\pi r}\right) = \frac{\mu_0 \ell I^2}{2\pi r}$$

Solve for I to obtain:

$$I=\sqrt{\frac{2\pi r F_{\text{lower wire}}}{\mu_0\ell}}$$

Note that the force on the lower wire is the increase in the reading of the balance. Substitute numerical values and evaluate I:

$$I=\sqrt{\frac{2\pi(2.00\text{ cm})(5.00\times10^{-6}\text{ kg})}{(4\pi\times10^{-7}\text{ N/A}^2)(10.0\text{ cm})}}$$
$$=2.236\text{ A}=\boxed{2.24\text{ A}}$$

96 •• Consider the current balance of Problem 95. If the sensitivity of the balance is 0.100 mg, what is the minimum current detectable using this current balance?

Picture the Problem We can use a proportion to relate minimum current detectible using this balance to its sensitivity and to the current and change in balance reading from Problem 95.

The minimum current I_{min} detectible is to the sensitivity of the balance as the current in Problem 95 is to the change in the balance reading in Problem 95:

$$\frac{I_{\text{min}}}{0.100\,\text{mg}}=\frac{2.236\,\text{A}}{5.00\,\text{mg}}$$

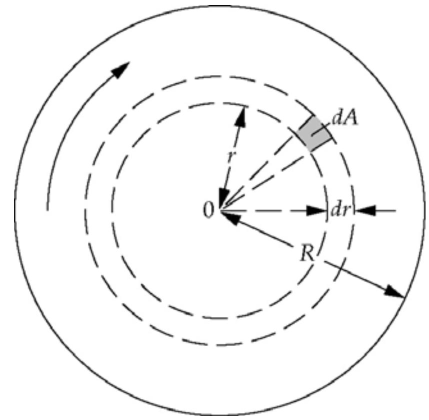
Solving for I_{min} yields:

$$I_{\text{min}}=(0.100\,\text{mg})\left(\frac{2.236\,\text{A}}{5.00\,\text{mg}}\right)$$
$$=\boxed{44.7\,\text{mA}}$$

The ″standard″ current balance can be made very sensitive by increasing the length (i.e., moment arm) of the wire balance, which one cannot do with this kind; however, this is compensated somewhat by the high sensitivity of the electronic balance.

97 ••• **[SSM]** A non-conducting disk that has radius R, carries a uniform surface charge density σ, and rotates with angular speed ω. (*a*) Consider an annular strip that has a radius r, a width dr, and a charge dq. Show that the current (dI) produced by this rotating strip is given by $\omega\sigma r dr$. (b) Use your result from Part (*a*) to show that the magnetic field strength at the center of the disk is given by the expression $\frac{1}{2}\mu_0\sigma\omega R$. (*c*) Use your result from Part (*a*) to find an expression for the magnetic field strength at a point on the central axis of the disk a distance z from its center.

Picture the Problem The diagram shows the rotating disk and the circular strip of radius *r* and width *dr* with charge *dq*. We can use the definition of surface charge density to express *dq* in terms of *r* and *dr* and the definition of current to show that $dI = \omega\sigma r\, dr$. We can then use this current and expression for the magnetic field on the axis of a current loop to obtain the results called for in Parts (*b*) and (*c*).



(*a*) Express the total charge *dq* that passes a given point on the circular strip once each period:

$$dq = \sigma dA = 2\pi\sigma r dr$$

Letting *q* be the total charge that passes along a radial section of the disk in a period of time *T*, express the current in the element of width *dr*:

$$dI = \frac{dq}{dt} = \frac{2\pi\sigma r dr}{\frac{2\pi}{\omega}} = \boxed{\omega\sigma r dr}$$

(*c*) Express the magnetic field dB_x at a distance *z* along the axis of the disk due to the current loop of radius *r* and width *dr*:

$$dB_x = \frac{\mu_0}{4\pi}\frac{2\pi r^2 dI}{\left(z^2 + r^2\right)^{3/2}} = \frac{\mu_0\omega\sigma r^3}{2\left(z^2 + r^2\right)^{3/2}}dr$$

Integrate from $r = 0$ to $r = R$ to obtain:

$$B_x = \frac{\mu_0\omega\sigma}{2}\int_0^R \frac{r^3}{\left(z^2 + r^2\right)^{3/2}}dr = \boxed{\frac{\mu_0\omega\sigma}{2}\left(\frac{R^2 + 2z^2}{\sqrt{R^2 + z^2}} - 2x\right)}$$

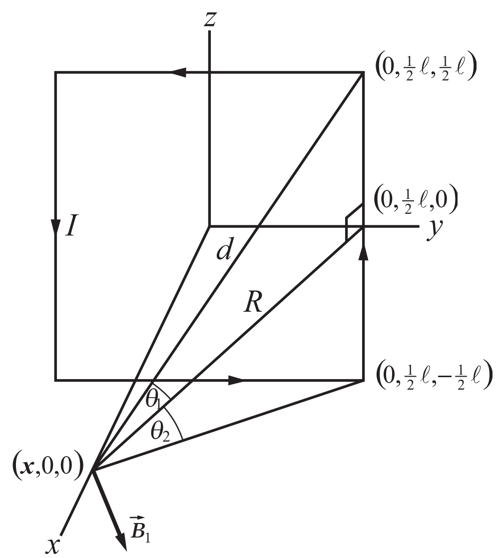
(*b*) Evaluate B_x for $x = 0$:

$$B_x(0) = \frac{\mu_0\omega\sigma}{2}\left(\frac{R^2}{\sqrt{R^2}}\right) = \boxed{\tfrac{1}{2}\mu_0\sigma\omega R}$$

98 ••• A square loop that has sides of length ℓ lies in the $z = 0$ plane with its center at the origin. The loop carries a current *I*. (*a*) Derive an expression for the magnetic field strength at any point on the *z* axis. (*b*) Show that for *z* much larger

than ℓ, your result from Part (*a*) becomes $B \approx \mu\mu_0/(2\pi z^3)$, where μ is the magnitude of the magnetic moment of the loop.

Picture the Problem From the symmetry of the system it is evident that the magnetic fields due to each segment have the same magnitude. We can express the magnetic field at (x,0,0) due to one side (segment) of the square, find its component in the x direction, and then multiply by four to find the resultant field.



(*a*) B due to a straight wire segment is given by:

$$B = \frac{\mu_0}{4\pi}\frac{I}{R}(\sin\theta_1 + \sin\theta_2)$$

where R is the perpendicular distance from the wire segment to the field point.

Use $\theta_1 = \theta_2$ and $R = \sqrt{x^2 + \ell^2/4}$ to express B due to one side at (x,0,0):

$$B_1(x,0,0) = \frac{\mu_0}{4\pi}\frac{I}{\sqrt{x^2 + \frac{\ell^2}{4}}}(2\sin\theta_1)$$

$$= \frac{\mu_0}{2\pi}\frac{I}{\sqrt{x^2 + \frac{\ell^2}{4}}}(\sin\theta_1)$$

Referring to the diagram, express $\sin\theta_1$:

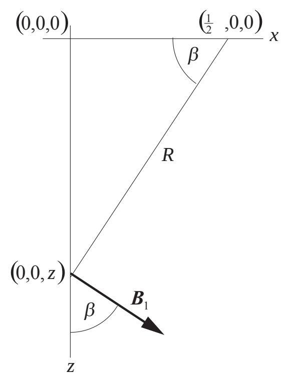
$$\sin\theta_1 = \frac{\frac{\ell}{2}}{d} = \frac{\frac{\ell}{2}}{\sqrt{x^2 + \frac{\ell^2}{2}}}$$

Substituting for $\sin\theta_1$ and simplifying yields:

$$B_1(x,0,0) = \frac{\mu_0}{2\pi}\frac{I}{\sqrt{x^2+\frac{\ell^2}{4}}}\frac{\frac{\ell}{2}}{\sqrt{x^2+\frac{\ell^2}{2}}}$$

$$= \frac{\mu_0 I}{4\pi\sqrt{x^2+\frac{\ell^2}{4}}}\frac{\ell}{\sqrt{x^2+\frac{\ell^2}{2}}}$$

By symmetry, the sum of the y and z components of the fields due to the four wire segments must vanish, whereas the x components will add. The diagram to the right is a view of the xy plane showing the relationship between $\vec{B}_1$ and the angle β it makes with the x axis.



Express B_{1x}:

$$B_{1x} = B_1\cos\beta$$

Substituting for $\cos\beta$ and simplifying yields:

$$B_{1x} = \frac{\mu_0 I}{4\pi\sqrt{x^2+\frac{\ell^2}{4}}}\frac{\ell}{\sqrt{x^2+\frac{\ell^2}{2}}}\frac{\frac{\ell}{2}}{\sqrt{x^2+\frac{\ell^2}{4}}}$$

$$= \frac{\mu_0 I\ell^2}{8\pi\left(x^2+\frac{\ell^2}{4}\right)\sqrt{x^2+\frac{\ell^2}{2}}}$$

The resultant magnetic field is the sum of the fields due to the four wire segments (sides of the square):

$$\vec{B} = 4B_{1x}\hat{\boldsymbol{i}}$$

$$= \boxed{\frac{\mu_0 I\ell^2}{2\pi\left(x^2+\frac{\ell^2}{4}\right)\sqrt{x^2+\frac{\ell^2}{2}}}\hat{\boldsymbol{i}}}$$

(*b*) Factor x^2 from the two factors in the denominator to obtain:

$$\vec{B} = \frac{\mu_0 I\ell^2}{2\pi x^2\left(1+\frac{\ell^2}{4x^2}\right)\sqrt{x^2\left(1+\frac{\ell^2}{2x^2}\right)}}\hat{i}$$

$$= \frac{\mu_0 I\ell^2}{2\pi x^3\left(1+\frac{\ell^2}{4x^2}\right)\sqrt{1+\frac{\ell^2}{2x^2}}}\hat{i}$$

For $x >> \ell$:

$$\vec{B} \approx \frac{\mu_0 I\ell^2}{2\pi x^3}\hat{i} = \boxed{\frac{\mu_0 \mu}{2\pi x^3}\hat{i}}$$

where $\mu = I\ell^2$.

Chapter 28
Magnetic Induction

Conceptual Problems

1 • [SSM] (*a*) The magnetic equator is a line on the surface of Earth on which Earth's magnetic field is horizontal. At the magnetic equator, how would you orient a flat sheet of paper so as to create the maximum magnitude of magnetic flux through it? (*b*) How about the minimum magnitude of magnetic flux?

Determine the Concept
(*a*) Orient the sheet so the normal to the sheet is both horizontal and perpendicular to the local tangent to the magnetic equator.

(*b*) Orient the sheet of paper so the normal to the sheet is perpendicular to the direction of the normal described in the answer to Part (*a*).

2 • At one of Earth's magnetic poles, how would you orient a flat sheet of paper so as to create the maximum magnitude of magnetic flux through it?

Determine the Concept
(*a*) Orient the sheet so the normal to the sheet is vertical.

(*b*) Any orientation as long as the paper's plane is perpendicular to Earth's surface at that location.

3 • [SSM] Show that the following combination of SI units is equivalent to the volt: $\mathrm{T\cdot m^2/s}$.

Determine the Concept Because a volt is a joule per coulomb, we can show that the SI units $\dfrac{\mathrm{T\cdot m^2}}{\mathrm{s}}$ are equivalent to a volt by making a series of substitutions and simplifications that reduces these units to a joule per coulomb.

The units of a tesla are $\dfrac{\mathrm{N}}{\mathrm{A\cdot m}}$:

$$\frac{\mathrm{T\cdot m^2}}{\mathrm{s}}=\frac{\dfrac{\mathrm{N}}{\mathrm{A\cdot m}}\cdot\mathrm{m^2}}{\mathrm{s}}=\frac{\dfrac{\mathrm{N\cdot m}}{\mathrm{A}}}{\mathrm{s}}$$

Substitute the units of an ampere (C/s), replace $\mathrm{N\cdot m}$ with J, and simplify to obtain:

$$\frac{\mathrm{T\cdot m^2}}{\mathrm{s}}=\frac{\dfrac{\mathrm{J}}{\dfrac{\mathrm{C}}{\mathrm{s}}}}{\mathrm{s}}=\frac{\mathrm{J}}{\mathrm{C}}$$

Finally, because a joule per coulomb is a volt:

$$\frac{\mathrm{T\cdot m^2}}{\mathrm{s}}=\boxed{\mathrm{V}}$$

4 • Show that the following combination of SI units is equivalent to the ohm: $\dfrac{\mathrm{Wb}}{\mathrm{A\cdot s}}$.

Determine the Concept Because a weber is a newton·meter per ampere, we can show that the SI units $\dfrac{\mathrm{Wb}}{\mathrm{A\cdot s}}$ are equivalent to an ohm by making a series of substitutions and simplifications that reduces these units to a volt per ampere.

Because a weber is a $\dfrac{\mathrm{N\cdot m}}{\mathrm{A}}$:

$$\frac{\mathrm{Wb}}{\mathrm{A\cdot s}}=\frac{\dfrac{\mathrm{N\cdot m}}{\mathrm{A}}}{\mathrm{A\cdot s}}=\frac{\mathrm{J}}{\mathrm{A^2\cdot s}}$$

Substitute the units of an ampere and simplify to obtain:

$$\frac{\mathrm{Wb}}{\mathrm{A\cdot s}}=\frac{\mathrm{J}}{\mathrm{A\cdot\dfrac{C}{s}\cdot s}}=\frac{\mathrm{J}}{\mathrm{A\cdot C}}$$

Finally, because a joule per coulomb is a volt:

$$\frac{\mathrm{Wb}}{\mathrm{A\cdot s}}=\frac{\mathrm{V}}{\mathrm{A}}=\boxed{\Omega}$$

5 • **[SSM]** A current is induced in a conducting loop that lies in a horizontal plane and the induced current is clockwise when viewed from above. Which of the following statements could be true? (*a*) A constant magnetic field is directed vertically downward. (*b*) A constant magnetic field is directed vertically upward. (*c*) A magnetic field whose magnitude is increasing is directed vertically downward. (*d*) A magnetic field whose magnitude is decreasing is directed vertically downward. (*e*) A magnetic field whose magnitude is decreasing is directed vertically upward.

Determine the Concept We know that the magnetic flux (in this case the magnetic field because the area of the conducting loop is constant and its orientation is fixed) must be changing so the only issues are whether the field is increasing or decreasing and in which direction. Because the direction of the magnetic field associated with the clockwise current is vertically downward, the changing field that is responsible for it must be either increasing vertically upward (not included in the list of possible answers) or a decreasing field directed into the page. $\boxed{(d)}$ is correct.

6 • Give the direction of the induced current in the circuit, shown on the right in Figure 28- 37, when the resistance in the circuit on the left is suddenly (*a*) increased and (*b*) decreased. Explain your answer.

Determine the Concept The induced emf and induced current in the circuit on the right are in such a direction as to oppose the change that produces them (Lenz's Law). We can determine the direction of the induced current in the circuit. Note that when R is constant, $\vec{B}$ in the circuit to the right points out of the paper.

(*a*) If R increases, I decreases and B in the circuit to the right decreases. Lenz's law tells us that the induced current is counterclockwise.

(*b*) If R decreases, I increases and B in the circuit to the right increases. Lenz's law tells us that the induced current is clockwise.

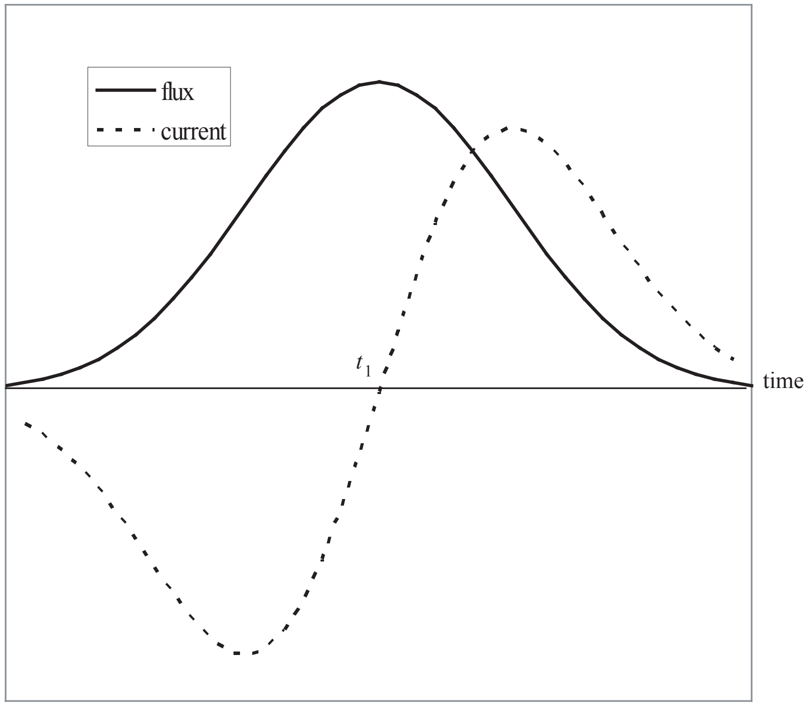
7 • **[SSM]** The planes of the two circular loops in Figure 28-38, are parallel. As viewed from the left, a counterclockwise current exists in loop A. If the magnitude of the current in loop A is increasing, what is the direction of the current induced in loop B? Do the loops attract or repel each other? Explain your answer.

Determine the Concept Clockwise as viewed from the left. The loops repel each other.

8 • A bar magnet moves with constant velocity along the axis of a loop, as shown in Figure 28-39, (*a*) Make a graph of the magnetic flux through the loop as a function of time. Indicate on the graph when the magnet is halfway through the loop by designating this time t_1. Choose the direction of the normal to the flat surface bounded by the flat surface to be to the right. (*b*) Make a graph of the induced current in the loop as a function of time. Choose the positive direction for the current to be clockwise as viewed from the left.

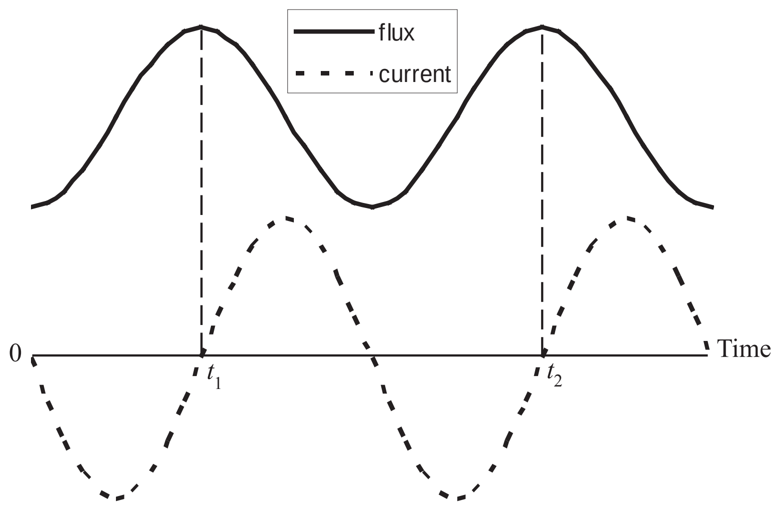
Determine the Concept We know that, as the magnet moves to the right, the flux through the loop first increases until the magnet is half way through the loop and then decreases. Because the flux first increases and then decreases, the current will change directions, having its maximum values when the flux is changing most rapidly.

(*a*) and (*b*) The following graph shows the flux and the induced current as a function of time as the bar magnet passes through the coil. When the center of the magnet passes through the plane of the coil $d\phi_m/dt = 0$ and the current is zero.



9 • A bar magnet is mounted on the end of a coiled spring and is oscillating in simple harmonic motion along the axis of a loop, as shown in Figure 28-40. The magnet is in its equilibrium position when its midpoint is in the plane of the loop. (*a*) Make a graph of the magnetic flux through the loop as a function of time. Indicate when the magnet is halfway through the loop by designating these times t_1 and t_2. (*b*) Make a graph of the induced current in the loop as a function of time, choosing the current to be positive when it is clockwise as viewed from above.

Determine the Concept Because the magnet moves with simple harmonic motion, the flux and the induced current will vary sinusoidally. The current will be a maximum wherever the flux is changing most rapidly and will be zero wherever the flux is momentarily constant. (*a*), (*b*) The following graph shows the flux, ϕ_m, and the induced current (proportional to $-d\phi_m/dt$) in the loop as a function of time.



10 • A pendulum is fabricated from a thin, flat piece of aluminum. At the bottom of its arc, it passes between the poles of a strong permanent magnet. In Figure 28-41*a*, the metal sheet is continuous, whereas in Figure 28-41*b*, there are slots in the sheet. When released from the same angle, the pendulum that has slots swings back and forth many times, but the pendulum that does not have slots stops swinging after no more than one complete oscillation. Explain why.

Determine the Concept In the configuration shown in (*a*), energy is dissipated by eddy currents from the emf induced by the pendulum movement. In the configuration shown in (*b*), the slits inhibit the eddy currents and the braking effect is greatly reduced.

11 • A bar magnet is dropped inside a long vertical tube. If the tube is made of metal, the magnet quickly approaches a terminal speed, but if the tube is made of cardboard, the magnet falls with constant acceleration. Explain why the magnet falls differently in the metal tube than it does in the cardboard tube.

Determine the Concept The magnetic field of the falling magnet sets up eddy currents in the metal tube. The eddy currents establish a magnetic field that exerts a force on the magnet opposing its motion; thus the magnet is slowed down. If the tube is made of a nonconducting material, there are no eddy currents.

12 • A small square wire loop lies in the plane of this page, and a constant magnetic field is directed into the page. The loop is moving to the right, which is the $+x$ direction. Find the direction of the induced current, if any, in the loop if (*a*) the magnetic field is uniform, (*b*) the magnetic field strength increases as x increases, and (*c*) the magnetic field strength decreases as x increases.

Determine the Concept The direction of the induced current is in such a direction as to oppose, or tend to oppose, the change that produces it (Lenz's Law).

(*a*) Because the applied field is constant and uniform, there is no change in flux through the loop and, in accord with Faraday's law, no induced current in the loop.

(*b*) Let the positive normal direction on the flat surface bounded by the loop be into the page. Because the strength of the applied field increases to the right, the flux through the loop increases as it moves to the right. In accord with Lenz's law, the direction of the induced current will be such that the flux through the loop due to its magnetic field will be opposite in sign the change in flux of the applied field. Thus, on the flat surface bounded by the loop the magnetic field due to the induced current is out of the page. Using the right-hand rule, the induced current must be counterclockwise.

(*c*) Let the positive normal direction on the flat surface bounded by the loop be into the page. Because the strength of the applied field increases to the right, the flux through the loop decreases as it moves to the right. In accord with Lenz's law, the direction of the induced current will be such that the flux through the loop due to its magnetic field will be opposite in sign the change in flux of the applied field. Thus, on the flat surface bounded by the loop the magnetic field due to the induced current is into the page. Using the right-hand rule, the induced current must be clockwise.

13 • If the current in an inductor doubles, the energy stored in the inductor will (*a*) remain the same, (*b*) double, (*c*) quadruple, (*d*) halve.

Determine the Concept The magnetic energy stored in an inductor is given by $U_m = \frac{1}{2}LI^2$. Doubling I quadruples U_m. $\boxed{(c)}$ is correct.

14 • Two solenoids are equal in length and radius, and the cores of both are identical cylinders of iron. However, solenoid A has three times the number of turns per unit length as solenoid B. (*a*) Which solenoid has the larger self-inductance? (*b*) What is the ratio of the self-inductance of solenoid A to the self-inductance of solenoid B?

Determine the Concept The self-inductance of a coil is given by $L = \mu_0 n^2 A\ell$, where n is the number of turns per unit length and ℓ is the length of the coil.

(*a*) Because the two solenoids are equal in length and radius and have identical cores, their self-inductances are proportional to the square of their number of turns per unit length. Hence A has the larger self-inductance.

(*b*) The self-inductances of the two coils are given by:

$$L_A = \mu_0 n_A^2 A_A \ell_A$$

and

$$L_B = \mu_0 n_B^2 A_B \ell_B$$

Divide the self-inductance of coil A by the self-inductance of coil B and simplify to obtain:

$$\frac{L_A}{L_B} = \frac{\mu_0 n_A^2 A_A \ell_A}{\mu_0 n_B^2 A_B \ell_B} = \frac{n_A^2 A_A \ell_A}{n_B^2 A_B \ell_B}$$

or, because the coils have the same lengths and radii (hence, the same cross-sectional areas),

$$\frac{L_A}{L_B} = \frac{n_A^2}{n_B^2} = \left(\frac{n_A}{n_B}\right)^2$$

If n increases by a factor of 3, ℓ will decrease by the same factor, because the inductors are made from the same length of wire. Hence:

$$\frac{L_A}{L_B} = \left(\frac{3n_B}{n_B}\right)^2 = \boxed{9}$$

15 • [SSM] True or false:

(*a*) The induced emf in a circuit is equal to the negative of the magnetic flux through the circuit.
(*b*) There can be a non-zero induced emf at an instant when the flux through the circuit is equal to zero.
(*c*) The self inductance of a solenoid is proportional to the rate of change of the current in the solenoid.
(*d*) The magnetic energy density at some point in space is proportional to the square of the magnitude of the magnetic field at that point.
(*e*) The inductance of a solenoid is proportional to the current in it.

(*a*) False. The induced emf in a circuit is equal to *the rate of change of* the magnetic flux through the circuit.

(*b*) True. The rate of change of the magnetic flux can be non-zero when the flux through the circuit is momentarily zero

(*c*) False. The self inductance of a solenoid is determined by its length, cross-sectional area, number of turns per unit length, and the permeability of the matter in its core.

(*d*) True. The magnetic energy density at some point in space is given by Equation 28-20: $u_m = \dfrac{B^2}{2\mu_0}$.

(*e*) False. The inductance of a solenoid is determined by its length, cross-sectional area, number of turns per unit length, and the permeability of the matter in its core.

Estimation and Approximation

16 • Your baseball teammates, having just studied this chapter, are concerned about generating enough voltage to shock them while swinging aluminum bats at fast balls. Estimate the maximum possible motional emf measured between the ends of an aluminum baseball bat during a swing. Do you think your team should switch to wooden bats to avoid electrocution?

Picture the Problem The bat is swung in Earth's magnetic field. We'll assume that the batter swings such that the maximum linear velocity of the bat occurs at an angle such that it is moving perpendicular to Earth's field (i.e. when the bat is aligned north-south and moving east-west). The induced emf in the bat is given by $\mathcal{E} = vB\ell$. A bat is roughly 1 m long, and at most its center is probably moving at 75 mph, or about 33 m/s. Earth's magnetic field is about 0.3 G.

The emf induced in the bat is given by:

$$\mathcal{E} = vB\ell$$

Under the conditions resulting in a maximum induced emf outlined above:

$$\mathcal{E} = (33\ \text{m/s})\left(0.3\ \text{G} \times \frac{1\ \text{T}}{10^4\ \text{G}}\right)(1\ \text{m}) \approx \boxed{1\ \text{mV}}$$

Because 1 mV is so low, there is no danger of being shocked and no reason to switch to wooden bats.

17 • Compare the energy density stored in Earth's electric field near its surface to that stored in Earth's magnetic field near its surface.

Picture the Problem We can compare the energy density stored in Earth's electric field to that of Earth's magnetic field by finding their ratio. We'll take Earth's magnetic field to be 0.3 G and its electric field to be 100 V/m.

The energy density in an electric field E is given by:

$$u_e = \tfrac{1}{2}\epsilon_0 E^2$$

The energy density in a magnetic field B is given by:

$$u_{\mathrm{m}} = \frac{B^2}{2\mu_0}$$

Express the ratio of u_{m} to u_{e} to obtain:

$$\frac{u_{\mathrm{m}}}{u_{\mathrm{e}}} = \frac{\dfrac{B^2}{2\mu_0}}{\frac{1}{2}\epsilon_0 E^2} = \frac{B^2}{\mu_0 \epsilon_0 E^2}$$

Substitute numerical values and evaluate $u_{\mathrm{m}}/ u_{\mathrm{e}}$:

$$\frac{u_{\mathrm{m}}}{u_{\mathrm{e}}} = \frac{\left(0.3\,\mathrm{G} \times \dfrac{1\,\mathrm{T}}{10^4\,\mathrm{G}}\right)^2}{\left(4\pi \times 10^{-7}\,\mathrm{N/A^2}\right)\left(8.854 \times 10^{-12}\,\mathrm{C^2/N\cdot m^2}\right)\left(100\,\mathrm{V/m}\right)^2} = 8.09 \times 10^3$$

or

$$u_{\mathrm{m}} \approx \boxed{\left(8 \times 10^3\right) u_{\mathrm{e}}}$$

18 •• A physics teacher does the following emf demonstration. She has two students hold a long wire connected to a voltmeter. The wire is held slack, so that it sags with a large arc in it. When she says ″start, ″the students begin rotating the wire as if they were playing jump rope. The students stand 3.0 m apart, and the sag in the wire is about 1.5 m. The motional emf from the ″jump rope″ is then measured on the voltmeter. (*a*) Estimate a reasonable value for the maximum angular speed that the students can rotate the wire. (*b*) From this, estimate the maximum motional emf in the wire. *HINT: What field is involved in creating the induced emf?*

Picture the Problem We can use Faraday's law to relate the motional emf in the wire to the angular speed with which the students turn the jump rope. Assume that Earth's magnetic field is 0.3 G.

(*a*) It seems unlikely that the students could turn the ″jump rope″ wire faster than 5.0 rev/s.

(*b*) The magnetic flux ϕ_{m} through the rotating circular loop of wire varies sinusoidally with time according to:

$$\phi_{\mathrm{m}} = BA\sin\omega t \Rightarrow \frac{d\phi_{\mathrm{m}}}{dt} = BA\omega\cos\omega t$$

Because the average value of the cosine function, over one revolution, is ½, the average rate at which the flux changes through the circular loop is:

$$\left.\frac{d\phi_{\mathrm{m}}}{dt}\right|_{\mathrm{av}} = \tfrac{1}{2}BA\omega = \tfrac{1}{2}\pi r^2 B\omega$$

From Faraday's law, the magnitude of the average motional emf in the loop is:

$$\mathcal{E} = \frac{d\phi_m}{dt} = \tfrac{1}{2}\pi r^2 B\omega$$

Substitute numerical values and evaluate $\mathcal{E}$:

$$\mathcal{E} = \tfrac{1}{2}\pi\left(\frac{1.5\,\text{m}}{2}\right)^2\left(0.3\,\text{G}\times\frac{1\,\text{T}}{10^4\,\text{G}}\right)(31.4\,\text{rad/s}) \approx \boxed{0.8\,\text{mV}}$$

19 •• (*a*) Estimate the maximum possible motional emf between the wingtips of a typical commercial airliner in flight. (*b*) Estimate the magnitude of the electric field between the wingtips.

Picture the Problem The motional emf between the wingtips of an airliner is given by $\mathcal{E} = vB\ell$. Assume a speed, relative to Earth's magnetic field, of 500 mi/h or about 220 m/s and a wingspan of 70 m. Assume that Earth's magnetic field is 0.3 G.

(*a*) The motional emf between the wingtips is given by:

$$\mathcal{E} = vB\ell$$

Substitute numerical values and evaluate $\mathcal{E}$:

$$\mathcal{E} = (220\,\text{m/s})\left(0.3\,\text{G}\times\frac{1\,\text{T}}{10^4\,\text{G}}\right)(70\,\text{m}) \approx \boxed{0.5\,\text{V}}$$

(*b*) The magnitude of the electric field between the wingtips is the ratio of the potential difference between them and their separation:

$$E = \frac{V}{d} = \frac{0.5\,\text{V}}{70\,\text{m}} \approx \boxed{7\,\text{mV/m}}$$

Magnetic Flux

20 • A uniform magnetic field of magnitude 0.200 T is in the +*x* direction. A square coil that has 5.00-cm long sides has a single turn and makes an angle θ with the z axis, as shown in Figure 28-42. Find the magnetic flux through the coil when θ is (*a*) 0º, (*b*) 30º, (*c*) 60º, and (*d*) 90º.

Picture the Problem Because the surface is a plane with area A and $\vec{B}$ is constant in magnitude and direction over the surface and makes an angle θ with the unit normal vector, we can use $\phi_m = BA\cos\theta$ to find the magnetic flux through the coil.

The magnetic flux through the coil is given by: $\phi_m = BA\cos\theta$

Substitute for B and A to obtain:

$$\phi_m = \left(2000\,\text{G}\cdot\frac{1\,\text{T}}{10^4\,\text{G}}\right)\left(5.00\times10^{-2}\,\text{m}\right)^2\cos\theta = \left(5.00\times10^{-4}\,\text{Wb}\right)\cos\theta$$

(*a*) For $\theta = 0°$:
$$\phi_m = \left(5.00\times10^{-4}\,\text{Wb}\right)\cos 0° = 5.00\times10^{-4}\,\text{Wb} = \boxed{0.50\,\text{mWb}}$$

(*b*) For $\theta = 30°$:
$$\phi_m = \left(5.00\times10^{-4}\,\text{Wb}\right)\cos 30° = 4.33\times10^{-4}\,\text{Wb} = \boxed{0.43\,\text{mWb}}$$

(*c*) For $\theta = 60°$:
$$\phi_m = \left(5.00\times10^{-4}\,\text{Wb}\right)\cos 60° = 2.50\times10^{-4}\,\text{Wb} = \boxed{0.25\,\text{mWb}}$$

(*d*) For $\theta = 90°$:
$$\phi_m = \left(5.00\times10^{-4}\,\text{Wb}\right)\cos 90° = \boxed{0}$$

21 • [SSM] A circular coil has 25 turns and a radius of 5.0 cm. It is at the equator, where Earth's magnetic field is 0.70 G, north. The axis of the coil is the line that passes through the center of the coil and is perpendicular to the plane of the coil. Find the magnetic flux through the coil when the axis of the coil is (*a*) vertical, (*b*) horizontal with the axis pointing north, (*c*) horizontal with the axis pointing east, and (*d*) horizontal with the axis making an angle of 30º with north.

Picture the Problem Because the coil defines a plane with area A and $\vec{B}$ is constant in magnitude and direction over the surface and makes an angle θ with the unit normal vector, we can use $\phi_m = NBA\cos\theta$ to find the magnetic flux through the coil.

The magnetic flux through the coil is given by: $\phi_m = NBA\cos\theta = NB\pi r^2\cos\theta$

Substitute for numerical values to obtain:

$$\phi_m = 25\left(0.70\,\text{G}\cdot\frac{1\,\text{T}}{10^4\,\text{G}}\right)\pi\left(5.0\times10^{-2}\,\text{m}\right)^2\cos\theta = \left(13.7\,\mu\text{Wb}\right)\cos\theta$$

(*a*) When the plane of the coil is horizontal, $\theta = 90°$:

$$\phi_{\mathrm{m}} = (13.7\,\mu\mathrm{Wb})\cos 90° = \boxed{0}$$

(*b*) When the plane of the coil is vertical with its axis pointing north, $\theta = 0°$:

$$\phi_{\mathrm{m}} = (13.7\,\mu\mathrm{Wb})\cos 0° = \boxed{14\,\mu\mathrm{Wb}}$$

(*c*) When the plane of the coil is vertical with its axis pointing east, $\theta = 90°$:

$$\phi_{\mathrm{m}} = (13.7\,\mu\mathrm{Wb})\cos 90° = \boxed{0}$$

(*d*) When the plane of the coil is vertical with its axis making an angle of 30° with north, $\theta = 30°$:

$$\phi_{\mathrm{m}} = (13.7\,\mu\mathrm{Wb})\cos 30° = \boxed{12\,\mu\mathrm{Wb}}$$

22 • A magnetic field of 1.2 T is perpendicular to the plane of a14 turn square coil with sides 5.0-cm long. (*a*) Find the magnetic flux through the coil. (*b*) Find the magnetic flux through the coil if the magnetic field makes an angle of 60º with the normal to the plane of the coil.

Picture the Problem Because the square coil defines a plane with area A and $\vec{B}$ is constant in magnitude and direction over the surface and makes an angle θ with the unit normal vector, we can use $\phi_{\mathrm{m}} = NBA\cos\theta$ to find the magnetic flux through the coil.

The magnetic flux through the coil is given by:

$$\phi_{\mathrm{m}} = NBA\cos\theta$$

Substitute numerical values for N, B, and A to obtain:

$$\begin{aligned}\phi_{\mathrm{m}} &= 14(1.2\,\mathrm{T})\left(5.0\times10^{-2}\,\mathrm{m}\right)^2\cos\theta \\ &= (42.0\,\mathrm{mWb})\cos\theta\end{aligned}$$

(*a*) For $\theta = 0°$:

$$\phi_{\mathrm{m}} = (42.0\,\mathrm{mWb})\cos 0° = \boxed{42\,\mathrm{mWb}}$$

(*b*) For $\theta = 60°$:

$$\phi_{\mathrm{m}} = (42.0\,\mathrm{mWb})\cos 60° = \boxed{21\,\mathrm{mWb}}$$

23 • A uniform magnetic field $\vec{B}$ is perpendicular to the base of a hemisphere of radius R. Calculate the magnetic flux (in terms of B and R) through the spherical surface of the hemisphere.

Picture the Problem Noting that the flux through the base must also penetrate the spherical surface (the ± in the answer below), we can apply its definition to express ϕ_m.

Apply the definition of magnetic flux to obtain:

$$\phi_m = \pm AB = \boxed{\pm\pi R^2 B}$$

24 • Find the magnetic flux through a 400-turn solenoid that has a length equal to 25.0 cm, has a radius equal to 1.00 cm, and carries a current of 3.00 A.

Picture the Problem We can use $\phi_m = NBA\cos\theta$ to express the magnetic flux through the solenoid and $B = \mu_0 nI$ to relate the magnetic field in the solenoid to the current in its coils. Assume that the magnetic field in the solenoid is constant.

Express the magnetic flux through a coil with N turns:

$$\phi_m = NBA\cos\theta$$

Express the magnetic field inside a long solenoid:

$$B = \mu_0 nI$$

where n is the number of turns per unit length.

Substitute to obtain:

$$\phi_m = N\mu_0 nIA\cos\theta$$

or, because $n = N/L$ and $\theta = 0°$,

$$\phi_m = \frac{N^2\mu_0 IA}{L} = \frac{N^2\mu_0 I\pi r^2}{L}$$

Substitute numerical values and evaluate ϕ_m:

$$\phi_m = \frac{(400)^2(4\pi\times10^{-7}\ \text{N/A}^2)(3.00\ \text{A})\pi(0.0100\ \text{m})^2}{0.250\ \text{m}} = \boxed{758\ \mu\text{Wb}}$$

25 • Find the magnetic flux through a 800-turn solenoid that has a length equal to 30.0 cm, has a radius equal to 2.00 cm, and carries a current of 2.00 A.

Picture the Problem We can use $\phi_m = NBA\cos\theta$ to express the magnetic flux through the solenoid and $B = \mu_0 nI$ to relate the magnetic field in the solenoid to the current in its coils. Assume that the magnetic field in the solenoid is constant.

Express the magnetic flux through a coil with N turns:

$$\phi_m = NBA\cos\theta$$

Express the magnetic field inside a long solenoid:

$$B = \mu_0 nI$$

where n is the number of turns per unit length.

Substitute for B to obtain:

$$\phi_m = N\mu_0 nIA\cos\theta$$

or, because $n = N/L$ and $\theta = 0°$,

$$\phi_m = \frac{N^2\mu_0 IA}{L} = \frac{N^2\mu_0 I\pi r^2}{L}$$

Substitute numerical values and evaluate ϕ_m:

$$\phi_m = \frac{(800)^2(4\pi\times10^{-7}\ \text{N/A}^2)(2.00\ \text{A})\pi(0.0200\ \text{m})^2}{0.300\ \text{m}} = \boxed{6.74\ \text{mWb}}$$

26 •• A circular coil has 15.0 turns, has a radius 4.00 cm, and is in a uniform magnetic field of 4.00 kG in the $+x$ direction. Find the flux through the coil when the unit normal to the plane of the coil is $(a)\,\hat{\boldsymbol{i}}$, $(b)\,\hat{\boldsymbol{j}}$, $(c)\,(\hat{\boldsymbol{i}}+\hat{\boldsymbol{j}})/\sqrt{2}$, $(d)\,\hat{\boldsymbol{k}}$, and $(e)\,0.60\hat{\boldsymbol{i}}+0.80\hat{\boldsymbol{j}}$.

Picture the Problem We can apply the definitions of magnet flux and of the dot product to find the flux for the given unit vectors.

Apply the definition of magnetic flux to the coil to obtain:

$$\phi_m = N\int_S \vec{\boldsymbol{B}}\cdot\hat{\boldsymbol{n}}\,dA$$

Because $\vec{\boldsymbol{B}}$ is constant:

$$\phi_m = N\vec{\boldsymbol{B}}\cdot\hat{\boldsymbol{n}}\int_S dA = N(\vec{\boldsymbol{B}}\cdot\hat{\boldsymbol{n}})A = N(\vec{\boldsymbol{B}}\cdot\hat{\boldsymbol{n}})\pi r^2$$

Evaluate $\vec{\boldsymbol{B}}$:

$$\vec{\boldsymbol{B}} = (0.400\,T)\hat{\boldsymbol{i}}$$

Substitute numerical values and simplify to obtain:

$$\phi_m = (15.0)[(0.400\ \text{T})]\pi(0.0400\ \text{m})^2 = (0.03016\ \text{T}\cdot\text{m}^2)\hat{\boldsymbol{i}}\cdot\hat{\boldsymbol{n}}$$

(a) Evaluate ϕ_m for $\hat{\boldsymbol{n}} = \hat{\boldsymbol{i}}$:

$$\phi_m = (0.03016\ \text{T}\cdot\text{m}^2)\hat{\boldsymbol{i}}\cdot\hat{\boldsymbol{i}} = \boxed{30.2\ \text{mWb}}$$

(b) Evaluate ϕ_m for $\hat{\boldsymbol{n}} = \hat{\boldsymbol{j}}$:

$$\phi_m = (0.03016\ \text{T}\cdot\text{m}^2)\hat{\boldsymbol{i}}\cdot\hat{\boldsymbol{j}} = \boxed{0}$$

(*c*) Evaluate ϕ_m for $\hat{\boldsymbol{n}} = (\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}})/\sqrt{2}$:

$$\phi_m = (0.03016\,\mathrm{T\cdot m^2})\hat{\boldsymbol{i}} \cdot \frac{(\hat{\boldsymbol{i}} + \hat{\boldsymbol{j}})}{\sqrt{2}} = \frac{0.03016\,\mathrm{T\cdot m^2}}{\sqrt{2}} = \boxed{21.3\,\mathrm{mWb}}$$

(*d*) Evaluate ϕ_m for $\hat{\boldsymbol{n}} = \hat{\boldsymbol{k}}$:

$$\phi_m = (0.03016\,\mathrm{T\cdot m^2})\hat{\boldsymbol{i}} \cdot \hat{\boldsymbol{k}} = \boxed{0}$$

(*e*) Evaluate ϕ_m for $\hat{\boldsymbol{n}} = 0.60\hat{\boldsymbol{i}} + 0.80\hat{\boldsymbol{j}}$:

$$\phi_m = (0.03016\,\mathrm{T\cdot m^2})\hat{\boldsymbol{i}} \cdot (0.60\hat{\boldsymbol{i}} + 0.80\hat{\boldsymbol{j}}) = \boxed{18\,\mathrm{mWb}}$$

27 •• **[SSM]** A long solenoid has n turns per unit length, has a radius R_1, and carries a current I. A circular coil with radius R_2 and with N total turns is coaxial with the solenoid and equidistant from its ends. (*a*) Find the magnetic flux through the coil if $R_2 > R_1$. (*b*) Find the magnetic flux through the coil if $R_2 < R_1$.

Picture the Problem The magnetic field outside the solenoid is, to a good approximation, zero. Hence, the flux through the coil is the flux in the core of the solenoid. The magnetic field inside the solenoid is uniform. Hence, the flux through the circular coil is given by the same expression with R_2 replacing R_1:

(*a*) The flux through the large circular loop outside the solenoid is given by:

$$\phi_m = NBA$$

Substituting for B and A and simplifying yields:

$$\phi_m = N(\mu_0 nI)(\pi R_1^2) = \boxed{\mu_0 nIN\pi R_1^2}$$

(*b*) The flux through the coil when $R_2 < R_1$ is given by:

$$\phi_m = N(\mu_0 nI)(\pi R_2^2) = \boxed{\mu_0 nIN\pi R_2^2}$$

28 ••• (*a*) Compute the magnetic flux through the rectangular loop shown in Figure 28-45. (*b*) Evaluate your answer for $a = 5.0$ cm, $b = 10$ cm, $d = 2.0$ cm, and $I = 20$ A.

Picture the Problem We can use the hint to set up the element of area dA and express the flux $d\phi_m$ through it and then carry out the details of the integration to express ϕ_m.

(*a*) The flux through the strip of area dA is given by:

$$d\phi_m = BdA$$

where $dA = bdx$.

Express B at a distance x from a long, straight wire:

$$B = \frac{\mu_0}{4\pi}\frac{2I}{x} = \frac{\mu_0}{2\pi}\frac{I}{x}$$

Substitute to obtain:

$$d\phi_m = \frac{\mu_0}{2\pi}\frac{I}{x}b\,dx = \frac{\mu_0 Ib}{2\pi}\frac{dx}{x}$$

Integrate from $x = d$ to $x = d + a$:

$$\phi_m = \frac{\mu_0 Ib}{2\pi}\int_d^{d+a}\frac{dx}{x} = \boxed{\frac{\mu_0 Ib}{2\pi}\ln\left(\frac{d+a}{d}\right)}$$

(*b*) Substitute numerical values and evaluate ϕ_m:

$$\phi_m = \frac{\left(4\pi\times10^{-7}\ \mathrm{N/A^2}\right)(20\ \mathrm{A})(0.10\ \mathrm{m})}{2\pi}\ln\left(\frac{7.0\ \mathrm{cm}}{2.0\ \mathrm{cm}}\right) = \boxed{0.50\ \mu\mathrm{Wb}}$$

29 ••• A long cylindrical conductor with a radius R and a length L carries a current I. Find the magnetic flux per unit length through the area indicated in Figure 28-44.

Picture the Problem Consider an element of area $dA = Ldr$ where $r \le R$. We can use its definition to express $d\phi_m$ through this area in terms of B and Ampere's law to express B as a function of I. The fact that the current is uniformly distributed over the cross-sectional area of the conductor allows us to set up a proportion from which we can obtain I as a function of r. With these substitutions in place we can integrate $d\phi_m$ to obtain ϕ_m/L.

Noting that $\vec{B}$ is parallel to $\hat{n}$ over the entire area, express the flux $d\phi_m$ through an area Ldr:

$$d\phi_m = BdA = BLdr \qquad (1)$$

Apply Ampere's law to the current contained inside a cylindrical region of radius $r < R$:

$$\oint_C \vec{\boldsymbol{B}}\cdot d\vec{\ell} = 2\pi rB = \mu_0 I_C$$

Solving for B yields:

$$B = \frac{\mu_0 I_C}{2\pi r} \qquad (2)$$

Using the fact that the current I is uniformly distributed over the cross-sectional area of the conductor, express its variation with distance r from the center of the conductor:

$$\frac{I(r)}{I} = \frac{\pi r^2}{\pi R^2} \Rightarrow I(r) = I_C = I\frac{r^2}{R^2}$$

Substitute for I_C in equation (2) and simplify to obtain:

$$B = \frac{\mu_0 I}{2\pi r}\frac{r^2}{R^2} = \frac{\mu_0 I}{2\pi R^2}r$$

Substituting for B in equation (1) yields:

$$d\phi_{\mathrm{m}} = \frac{\mu_0 LI}{2\pi R^2}rdr$$

Integrate $d\phi_{\mathrm{m}}$ from $r = 0$ to $r = R$ to obtain:

$$\phi_{\mathrm{m}} = \frac{\mu_0 LI}{2\pi R^2}\int_0^R rdr = \frac{\mu_0 LI}{4\pi}$$

Divide both sides of this equation by L to express the magnetic flux per unit length:

$$\frac{\phi_{\mathrm{m}}}{L} = \boxed{\frac{\mu_0 I}{4\pi}}$$

Induced EMF and Faraday's Law

30 • The flux through a loop is given by $\phi_{\mathrm{m}} = 0.10t^2 - 0.40t$, where ϕ_{m} is in webers and t is in seconds. (a) Find the induced emf as a function of time. (b) Find both ϕ_{m} and $\mathcal{E}$ at $t = 0$, $t = 2.0$ s, $t = 4.0$ s, and $t = 6.0$ s.

Picture the Problem Given ϕ_{m} as a function of time, we can use Faraday's law to express $\mathcal{E}$ as a function of time.

(a) Apply Faraday's law to express the induced emf in the loop in terms of the rate of change of the magnetic flux:

$$\mathcal{E}(t) = -\frac{d\phi_{\mathrm{m}}}{dt} = -\frac{d}{dt}\left[0.10\left(t^2 - 0.40t\right)\right]$$
$$= -(0.20t - 0.40)\frac{\mathrm{Wb}}{\mathrm{s}}$$
$$= \boxed{-(0.20t - 0.40)\,\mathrm{V}}$$

where $\mathcal{E}$ is in volts and t is in seconds.

(b) Evaluate ϕ_{m} at $t = 0$:

$$\phi_{\mathrm{m}}(0\,\mathrm{s}) = 0.10(0)^2 - (0.40)(0) = \boxed{0}$$

Evaluate $\mathcal{E}$ at $t = 0$:

$$\mathcal{E}(0\,\mathrm{s}) = -[0.20(0) - 0.40]\mathrm{V} = \boxed{0.40\,\mathrm{V}}$$

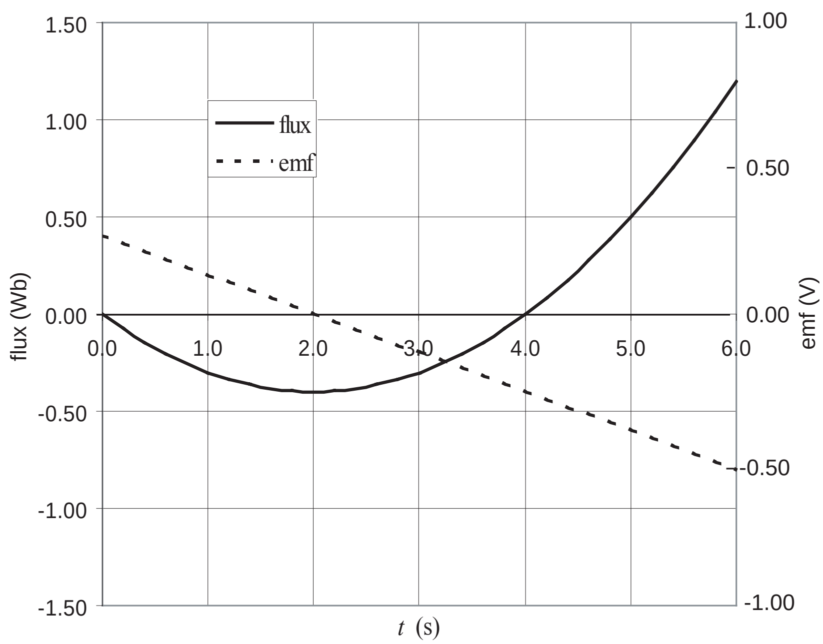
Proceed as above to complete the table to the right:

t	ϕ_{m}	$\mathcal{E}$
(s)	(Wb)	(V)
0	0	0.40
2.0	–0.40	0.00
4.0	0.0	–0.40
6.0	1.2	–0.80

31 • The flux through a loop is given by $\phi_m = 0.10t^2 - 0.40t$, where ϕ_m is in webers and t is in seconds. (*a*) Sketch graphs of magnetic flux and induced emf as a function of time. (*b*) At what time(s) is the flux minimum? What is the induced emf at that (those) time(s)? (*c*) At what time(s) is the flux zero? What is (are) the induced emf(s) at those time(s)?

Picture the Problem We can find the time at which the flux is a minimum by looking for the lowest point on the graph of $\mathcal{E}$ versus t and the emf at this time by determining the value of V at this time from the graph. We can interpret the graphs to find the times at which the flux is zero and the corresponding values of the emf.

(*a*) The flux, ϕ_m, and the induced emf, $\mathcal{E}$, are shown as functions of t in the following graph. The solid curve represents ϕ_m, the dashed curve represents $\mathcal{E}$.



(*b*) Referring to the graph, we see that the flux is a minimum when $t = 2.0$ s and that $V(2.0\text{ s}) = 0$.

(*c*) The flux is zero when $t = 0$ and $t = 4.0$ s. $\mathcal{E}(0) = 0.40$ V and

$\mathcal{E}(4.0\text{ s}) = -0.40$ V.

32 • A solenoid that has a length equal to 25.0 cm, a radius equal to 0.800 cm, and 400 turns is in a region where a magnetic field of 600 G exists and makes an angle of 50º with the axis of the solenoid. (*a*) Find the magnetic flux

through the solenoid. (*b*) Find the magnitude of the average emf induced in the solenoid if the magnetic field is reduced to zero in 1.40 s.

Picture the Problem We can use its definition to find the magnetic flux through the solenoid and Faraday's law to find the emf induced in the solenoid when the external field is reduced to zero in 1.4 s.

(*a*) Express the magnetic flux through the solenoid in terms of N, B, A, and θ:

$$\phi_{\mathrm{m}} = NBA\cos\theta = NB\pi R^2\cos\theta$$

Substitute numerical values and evaluate ϕ_{m}:

$$\phi_{\mathrm{m}} = (400)(60.0\,\mathrm{mT})\pi(0.00800\,\mathrm{m})^2\cos 50° = 3.10\,\mathrm{mWb} = \boxed{3.1\,\mathrm{mWb}}$$

(*b*) Apply Faraday's law to obtain:

$$\mathcal{E} = -\frac{\Delta\phi_{\mathrm{m}}}{\Delta t} = -\frac{0 - 3.10\,\mathrm{mWb}}{1.40\,\mathrm{s}} = \boxed{2.2\,\mathrm{mV}}$$

33 •• [SSM] A 100-turn circular coil has a diameter of 2.00 cm, a resistance of 50.0 Ω, and the two ends of the coil are connected together. The plane of the coil is perpendicular to a uniform magnetic field of magnitude 1.00 T. The direction of the field is reversed. (*a*) Find the total charge that passes through a cross section of the wire. If the reversal takes 0.100 s, find (*b*) the average current and (*c*) the average emf during the reversal.

Picture the Problem We can use the definition of average current to express the total charge passing through the coil as a function of I_{av}. Because the induced current is proportional to the induced emf and the induced emf, in turn, is given by Faraday's law, we can express ΔQ as a function of the number of turns of the coil, the magnetic field, the resistance of the coil, and the area of the coil. Knowing the reversal time, we can find the average current from its definition and the average emf from Ohm's law.

(*a*) Express the total charge that passes through the coil in terms of the induced current:

$$\Delta Q = I_{\mathrm{av}}\Delta t \qquad (1)$$

Relate the induced current to the induced emf:

$$I = I_{\mathrm{av}} = \frac{\mathcal{E}}{R}$$

Using Faraday's law, express the induced emf in terms of ϕ_m:

$$\mathcal{E} = -\frac{\Delta\phi_m}{\Delta t}$$

Substitute in equation (1) and simplify to obtain:

$$\Delta Q = \frac{|\mathcal{E}|}{R}\Delta t = \frac{\dfrac{\Delta\phi_m}{\Delta t}}{R}\Delta t = \frac{2\phi_m}{R}$$

$$= \frac{2NBA}{R} = \frac{2NB\left(\dfrac{\pi}{4}d^2\right)}{R}$$

$$= \frac{NB\pi d^2}{2R}$$

where d is the diameter of the coil.

Substitute numerical values and evaluate ΔQ:

$$\Delta Q = \frac{(100)(1.00\,\text{T})\pi(0.0200\,\text{m})^2}{2(50.0\,\Omega)}$$

$$= 1.257\,\text{mC} = \boxed{1.26\,\text{mC}}$$

(*b*) Apply the definition of average current to obtain:

$$I_{av} = \frac{\Delta Q}{\Delta t} = \frac{1.257\,\text{mC}}{0.100\,\text{s}} = 12.57\,\text{mA}$$

$$= \boxed{12.6\,\text{mA}}$$

(*c*) Using Ohm's law, relate the average emf in the coil to the average current:

$$\mathcal{E}_{av} = I_{av}R = (12.57\,\text{mA})(50.0\,\Omega)$$

$$= \boxed{628\,\text{mV}}$$

34 •• At the equator, a 1000-turn coil that has a cross-sectional area of 300 cm^2 and a resistance of 15.0 Ω is aligned so that its plane is perpendicular to Earth's magnetic field of 0.700 G. (*a*) If the coil is flipped over in 0.350 s, what is the average induced current in it during the 0.350 s? (*b*) How much charge flows through a cross section of the coil wire during the 0.350 s?

Picture the Problem (*a*) Because the average induced current is proportional to the induced emf and the induced emf, in turn, is given by Faraday's law, we can find I_{av} from the change in the magnetic flux through the coil, the resistance of the coil, and the time required for the flipping of the coil. (*b*) Knowing the average current, we can use its definition to find the charge flowing in the coil.

(*a*) The average induced current is given by:

$$I_{av} = \frac{\mathcal{E}}{R}$$

The induced emf in the coil is the rate at which the magnetic flux is changing:

$$\mathcal{E}=\frac{\Delta\phi_{\mathrm{m}}}{\Delta t}=\frac{2\phi_{\mathrm{m}}}{\Delta t}=\frac{2NBA}{\Delta t}$$

Substituting for $\mathcal{E}$ yields:

$$I_{\mathrm{av}}=\frac{2NBA}{R\Delta t}$$

Substitute numerical values and evaluate I_{av}:

$$I_{\mathrm{av}}=\frac{2(1000)\left(0.700\ \mathrm{G}\times\frac{1\ \mathrm{T}}{10^4\ \mathrm{G}}\right)\left(300\ \mathrm{cm}^2\times\left(\frac{1\ \mathrm{m}}{10^2\ \mathrm{cm}}\right)^2\right)}{(15.0\ \Omega)(0.350\ \mathrm{s})}=\boxed{800\ \mu\mathrm{A}}$$

(*b*) The average current is also given by:

$$I_{\mathrm{av}}=\frac{\Delta Q}{\Delta t}\Rightarrow\Delta Q=I_{\mathrm{av}}\Delta t$$

Substitute numerical values and evaluate ΔQ:

$$\Delta Q=(0.800\ \mathrm{mA})(0.350\ \mathrm{s})=\boxed{280\ \mu\mathrm{C}}$$

35 •• A *current integrator* measures the current as a function of time and integrates (adds) the current to find the total charge passing through it. (Because $I = dq/dt$, the integrator calculates the integral of the current or $Q=\int I dt$.) A circular coil that has 300 turns and a radius equal to 5.00 cm is connected to such an instrument. The total resistance of the circuit is 20.0 Ω. The plane of the coil is originally aligned perpendicular to Earth's magnetic field at some point. When the coil is rotated through 90º about an axis that is in the plane of the coil, a charge of 9.40 μC passes through the current integrator is measured to be 9.40 μC. Calculate the magnitude of Earth's magnetic field at that point.

Picture the Problem We can use Faraday's law to express Earth's magnetic field at this location in terms of the induced emf and Ohm's law to relate the induced emf to the charge that passes through the current integrator.

Using Faraday's law, express the induced emf in terms of the change in the magnetic flux as the coil is rotated through 90°:

$$\mathcal{E}=\left|-\frac{\Delta\phi_{\mathrm{m}}}{\Delta t}\right|=\frac{NBA}{\Delta t}=\frac{NB\pi r^2}{\Delta t}$$

Solving for B yields:

$$B=\frac{\mathcal{E}\Delta t}{N\pi r^2}$$

Using Ohm's law, relate the induced emf to the induced current:

$$\mathcal{E} = IR = \frac{\Delta Q}{\Delta t}R$$

where ΔQ is the charge that passes through the current integrator.

Substitute for $\mathcal{E}$ and simplify to obtain:

$$B = \frac{\frac{\Delta Q}{\Delta t}R\Delta t}{N\pi r^2} = \frac{\Delta QR}{N\pi r^2}$$

Substitute numerical values and evaluate B:

$$B = \frac{(9.40\,\mu\text{C})(20.0\,\Omega)}{(300)\pi(0.0500\,\text{m})^2} = \boxed{79.8\,\mu\text{T}}$$

Motional EMF

36 •• A 30.0-cm long rod moves steadily at 8.00 m/s in a plane that is perpendicular to a magnetic field of 500 G. The velocity of the rod is perpendicular to its length. Find (*a*) the magnetic force on an electron in the rod, (*b*) the electrostatic field in the rod, and (*c*) the potential difference between the ends of the rod.

Picture the Problem We can apply the equation for the force on a charged particle moving in a magnetic field to find the magnetic force acting on an electron in the rod. We can use $\vec{E} = \vec{v} \times \vec{B}$ to find E and $V = E\ell$, where ℓ is the length of the rod, to find the potential difference between its ends.

(*a*) Relate the magnetic force on an electron in the rod to the speed of the rod, the electronic charge, and the magnetic field in which the rod is moving:

$$\vec{F} = q\vec{v} \times \vec{B}$$

and

$$F = qvB\sin\theta$$

Substitute numerical values and evaluate F:

$$F = (1.602\times10^{-19}\,\text{C})(8.00\,\text{m/s})\times(0.0500\,\text{T})\sin 90° = \boxed{6.4\times10^{-20}\,\text{N}}$$

(*b*) Express the electrostatic field $\vec{E}$ in the rod in terms of the magnetic field $\vec{B}$:

$\vec{E} = \vec{v} \times \vec{B}$ and $E = vB\sin\theta$ where θ is the angle between $\vec{v}$ and $\vec{B}$.

Substitute numerical values and evaluate B:

$$E = (8.00\,\text{m/s})(0.0500\,\text{T})\sin 90° = 0.400\,\text{V/m} = \boxed{0.40\,\text{V/m}}$$

(c) Relate the potential difference between the ends of the rod to its length ℓ and the electric field E:

$$V = E\ell$$

Substitute numerical values and evaluate V:

$$V = (0.400\,\text{V/m})(0.300\,\text{m}) = \boxed{0.12\,\text{V}}$$

37 •• A 30.0-cm long rod moves in a plane that is perpendicular to a magnetic field of 500 G. The velocity of the rod is perpendicular to its length. Find the speed of the rod if the potential difference between the ends is 6.00 V.

Picture the Problem We can use $\vec{E} = \vec{v} \times \vec{B}$ to relate the speed of the rod to the electric field in the rod and magnetic field in which it is moving and $V = E\ell$ to relate the electric field in the rod to the potential difference between its ends.

Express the electrostatic field $\vec{E}$ in the rod in terms of the magnetic field $\vec{B}$ and solve for v:

$\vec{E} = \vec{v} \times \vec{B}$ and $v = \dfrac{E}{B\sin\theta}$ where θ is the angle between $\vec{v}$ and $\vec{B}$.

Relate the potential difference between the ends of the rod to its length ℓ and the electric field E and solve for E:

$$V = E\ell \Rightarrow E = \frac{V}{\ell}$$

Substitute for E to obtain:

$$v = \frac{V}{B\ell\sin\theta}$$

Substitute numerical values and evaluate v:

$$v = \frac{6.00\,\text{V}}{(0.0500\,\text{T})(0.300\,\text{m})\sin 90°} = \boxed{400\,\text{m/s}}$$

38 •• In Figure 28-45, let the magnetic field strength be 0.80 T, the rod speed be 10 m/s, the rod length be 20 cm, and the resistance of the resistor be 2.0 Ω. (The resistance of the rod and rails are negligible.) Find (a) the induced emf in the circuit, (b) the induced current in the circuit (including direction), and (c) the force needed to move the rod with constant speed (assuming negligible friction). Find (d) the power delivered by the force found in Part (c) and (e) the rate of Joule heating in the resistor.

Picture the Problem Because the speed of the rod is constant, an external force must act on the rod to counter the magnetic force acting on the induced current. We can use the motional-emf equation $\mathcal{E} = vB\ell$ to evaluate the induced emf, Ohm's law to find the current in the circuit, Newton's second law to find the force needed to move the rod with constant speed, and $P = Fv$ to find the power input by the force.

(*a*) Relate the induced emf in the circuit to the speed of the rod, the magnetic field, and the length of the rod:

$$\mathcal{E} = vB\ell = (10\,\text{m/s})(0.80\,\text{T})(0.20\,\text{m}) = 1.60\,\text{V} = \boxed{1.6\,\text{V}}$$

(*b*) Using Ohm's law, relate the current in the circuit to the induced emf and the resistance of the circuit:

$$I = \frac{\mathcal{E}}{R} = \frac{1.60\,\text{V}}{2.0\,\Omega} = \boxed{0.80\,\text{A}}$$

Note that, because the rod is moving to the right, the flux in the region defined by the rod, the rails, and the resistor is increasing. Hence, in accord with Lenz's law, the current must be counterclockwise if its magnetic field is to counter this increase in flux.

(*c*) Because the rod is moving with constant speed in a straight line, the net force acting on it must be zero. Apply Newton's second law to relate F to the magnetic force F_{m}:

$$\sum F_x = F - F_{\text{m}} = 0$$

Solving for F and substituting for F_{m} yields:

$$F = F_{\text{m}} = BI\ell$$

Substitute numerical values and evaluate F:

$$F = (0.80\,\text{T})(0.80\,\text{A})(0.20\,\text{m}) = 0.128\,\text{N} = \boxed{0.13\,\text{N}}$$

(*d*) Express the power input by the force in terms of the force and the velocity of the rod:

$$P = Fv = (0.128\,\text{N})(10\,\text{m/s}) = \boxed{1.3\,\text{W}}$$

(*e*) The rate of Joule heat production is given by:

$$P = I^2R = (0.80\,\text{A})^2(2.0\,\Omega) = \boxed{1.3\,\text{W}}$$

39 •• A 10-cm by 5.0-cm rectangular loop (Figure 28-46) that has a resistance equal to 2.5 Ω moves at a constant speed of 2.4 cm/s through a region that has a uniform 1.7-T magnetic field directed out of the page as shown. The front of the loop enters the field region at time $t = 0$. (*a*) Graph the flux through the loop as a function of time. (*b*) Graph the induced emf and the current in the loop as functions of time. Neglect any self-inductance of the loop and construct your graphs to include the interval $0 \le t \le 16$ s.

Picture the Problem We'll need to determine how long it takes for the loop to completely enter the region in which there is a magnetic field, how long it is in the region, and how long it takes to leave the region. Once we know these times, we can use its definition to express the magnetic flux as a function of time. We can use Faraday's law to find the induced emf as a function of time.

(*a*) Find the time required for the loop to enter the region where there is a uniform magnetic field:

$$t = \frac{\ell_{\text{side of loop}}}{v} = \frac{10\,\text{cm}}{2.4\,\text{cm/s}} = 4.17\,\text{s}$$

Letting w represent the width of the loop, express and evaluate ϕ_m for $0 < t < 4.17\,\text{s}$:

$$\begin{aligned}\phi_m &= NBA = NBwvt\\ &= (1.7\,\text{T})(0.050\,\text{m})(0.024\,\text{m/s})t\\ &= (2.04\,\text{mWb/s})t\end{aligned}$$

Find the time during which the loop is fully in the region where there is a uniform magnetic field:

$$t = \frac{\ell_{\text{side of loop}}}{v} = \frac{10\,\text{cm}}{2.4\,\text{cm/s}} = 4.17\,\text{s}$$

that is, the loop will begin to exit the region when $t = 8.33$ s.

Express ϕ_m for $4.17\,\text{s} < t < 8.33\,\text{s}$:

$$\begin{aligned}\phi_m &= NBA = NB\ell w\\ &= (1.7\,\text{T})(0.10\,\text{m})(0.050\,\text{m})\\ &= 8.50\,\text{mWb}\end{aligned}$$

The left-end of the loop will exit the field when $t = 12.5$ s. Express ϕ_m for $8.33\,\text{s} < t < 12.5\,\text{s}$:

$$\phi_m = mt + b$$

where m is the slope of the line and b is the ϕ_m-intercept.

For $t = 8.33$ s and $\phi_m = 8.50$ mWb:

$$8.50\,\text{mWb} = m(8.33\,\text{s}) + b \qquad (1)$$

For $t = 12.5$ s and $\phi_m = 0$:

$$0 = m(12.5\,\text{s}) + b \qquad (2)$$

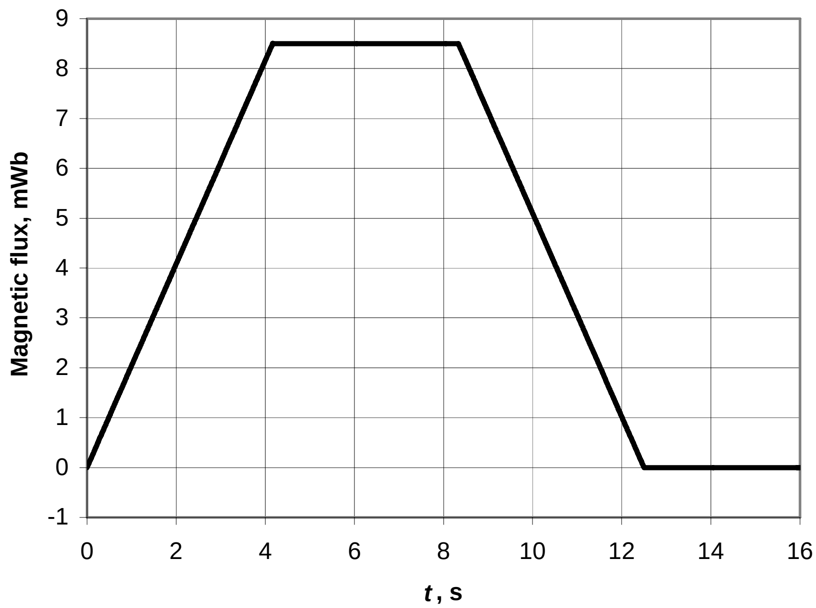
Solve equations (1) and (2) simultaneously to obtain:

$$\phi_m = -(2.04\,\text{mWb/s})t + 25.5\,\text{mWb}$$

The loop will be completely out of the magnetic field when $t > 12.5$ s and:

$$\phi_{\mathrm{m}} = 0$$

The following graph of $\phi_{\mathrm{m}}(t)$ was plotted using a spreadsheet program.



(*b*) Using Faraday's law, relate the induced emf to the magnetic flux:

$$\mathcal{E} = -\frac{d\phi_{\mathrm{m}}}{dt}$$

During the interval $0 < t < 4.17\,\mathrm{s}$:

$$\mathcal{E} = -\frac{d}{dt}\left[(2.04\,\mathrm{mWb/s})t\right] = -2.04\,\mathrm{mV}$$

During the interval $4.17\,\mathrm{s} < t < 8.33\,\mathrm{s}$:

$$\mathcal{E} = -\frac{d}{dt}\left[8.50\,\mathrm{mWb}\right] = 0$$

During the interval $8.33\,\mathrm{s} < t < 12.5\,\mathrm{s}$:

$$\mathcal{E} = -\frac{d}{dt}\left[(-2.04\,\mathrm{mWb/s})t + 25.5\,\mathrm{mWb}\right] = 2.04\,\mathrm{mV}$$

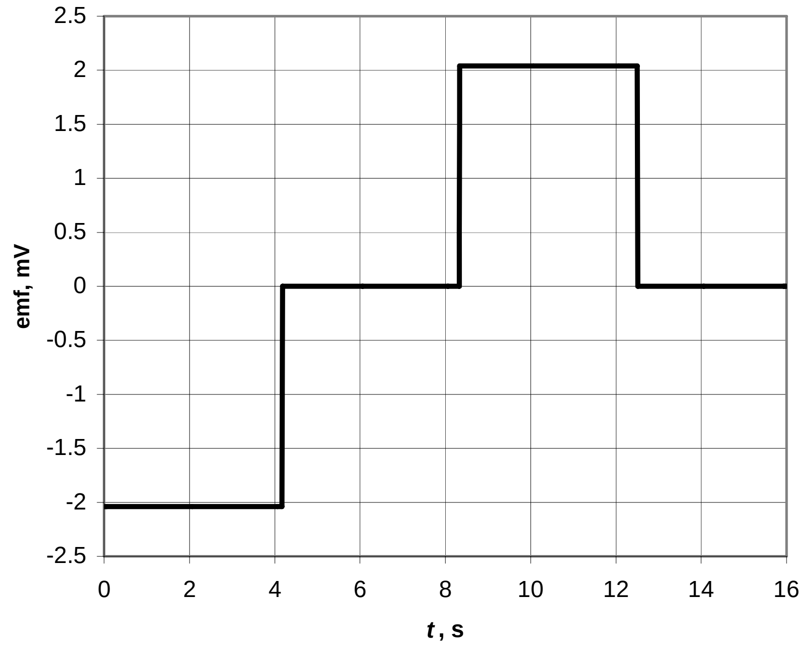
For $t > 12.5$ s:

$$\mathcal{E} = 0$$

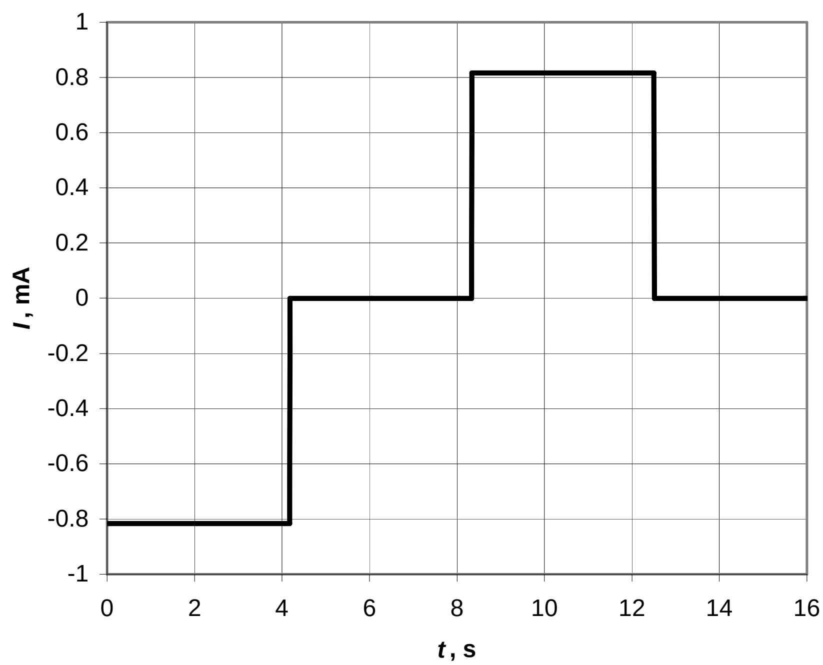
The current in each of these intervals is given by Ohm's law:

$$I = \frac{\mathcal{E}}{R}$$

The following graph of $\mathcal{E}(t)$ was plotted using a spreadsheet program.



The following graph of $I(t)$ was plotted using a spreadsheet program.



40 •• A uniform 1.2-T magnetic field is in the +*z* direction. A conducting rod of length 15 cm lies parallel to the *y* axis and oscillates in the *x* direction with displacement given by $x = (2.0\text{ cm})\cos(120\pi t)$, where 120π has units of rad/s . (*a*) Find an expression for the potential difference between the ends the rod as a function of time? (*b*) What is the maximum potential difference between the ends the rod?

Picture the Problem The rod is executing simple harmonic motion in the *xy* plane, i.e., in a plane perpendicular to the magnetic field. The emf induced in the rod is a consequence of its motion in this magnetic field and is given by $|\mathcal{E}| = vB\ell$. Because we're given the position of the oscillator as a function of time, we can differentiate this expression to obtain *v*.

(*a*) The potential difference between the ends of the rod is given by:

$$\mathcal{E} = vB\ell = B\ell\frac{dx}{dt}$$

Evaluate *dx*/*dt*:

$$\begin{aligned}\frac{dx}{dt} &= \frac{d}{dt}\left[(2.0\,\text{cm})\cos 120\pi t\right]\\ &= -(2.0\,\text{cm})\left(120\,\text{s}^{-1}\right)\pi\sin 120\pi t\\ &= -(7.54\,\text{m/s})\sin 120\pi t\end{aligned}$$

Substitute numerical values and evaluate $\mathcal{E}$:

$$\mathcal{E} = -(1.2\,\text{T})(0.15\,\text{m})(7.54\,\text{m/s})\sin 120\pi t = \boxed{-(1.4\,\text{V})\sin 120\pi t}$$

(*b*) The maximum potential difference between the ends the rod is the amplitude of the expression for $\mathcal{E}$ derived in Part (*a*):

$$\mathcal{E}_{\text{max}} = \boxed{1.4\,\text{V}}$$

41 •• **[SSM]** In Figure 28-47, the rod has a mass *m* and a resistance *R*. The rails are horizontal, frictionless and have negligible resistances. The distance between the rails is ℓ. An ideal battery that has an emf $\mathcal{E}$ is connected between points *a* and *b* so that the current in the rod is downward. The rod released from rest at $t = 0$. (*a*) Derive an expression for the force on the rod as a function of the speed. (*b*) Show that the speed of the rod approaches a terminal speed and find an expression for the terminal speed. (*c*) What is the current when the rod is moving at its terminal speed?

Picture the Problem (*a*) The net force acting on the rod is the magnetic force it experiences as a consequence of carrying a current and being in a magnetic field. The net emf that drives *I* in this circuit is the difference between the emf of the

battery and the emf induced in the rod as a result of its motion. Applying a right-hand rule to the rod reveals that the direction of this magnetic force is to the right. Hence the rod will accelerate to the right when it is released. (*b*) We can obtain the equation of motion of the rod by applying Newton's second law to relate its acceleration to $\mathcal{E}$, B, I, R and ℓ. (*c*) Letting $v = v_t$ in the equation for the current in the circuit will yield current when the rod is at its terminal speed.

(*a*) Express the magnetic force on the current-carrying rod:

$$F_m = I\ell B$$

The current in the rod is given by:

$$I = \frac{\mathcal{E} - B\ell v}{R} \qquad (1)$$

Substituting for I yields:

$$F_m = \left(\frac{\mathcal{E} - B\ell v}{R}\right)\ell B = \boxed{\frac{B\ell}{R}\left(\mathcal{E} - B\ell v\right)}$$

(*b*) Letting the direction of motion of the rod be the positive x direction, apply $\sum F_x = ma_x$ to the rod:

$$\frac{B\ell}{R}\left(\mathcal{E} - B\ell v\right) = m\frac{dv}{dt}$$

Solving for dv/dt yields:

$$\frac{dv}{dt} = \frac{B\ell}{mR}\left(\mathcal{E} - B\ell v\right)$$

Note that as v increases, $\mathcal{E} - B\ell v \to 0$, $dv/dt \to 0$ and the rod approaches its terminal speed v_t. Set $dv/dt = 0$ to obtain:

$$\frac{B\ell}{mR}\left(\mathcal{E} - B\ell v_t\right) = 0 \Rightarrow v_t = \boxed{\frac{\mathcal{E}}{B\ell}}$$

(*c*) Substitute v_t for v in equation (1) to obtain:

$$I = \frac{\mathcal{E} - B\ell\dfrac{\mathcal{E}}{B\ell}}{R} = \boxed{0}$$

42 • A uniform magnetic field is established perpendicular to the plane of a loop that has a radius equal to 5.00 cm and a resistance equal to 0.400 Ω. The magnitude of the field is increasing at a rate of 40.0 mT/s. Find (*a*) the magnitude of the induced emf in the loop, (*b*) the induced current in the loop, and (*c*) the rate of Joule heating in the loop.

Picture the Problem (*a*) We can find the magnitude of the induced emf by applying Faraday's law to the loop. (*b*) and (*c*) The application of Ohm's law will yield the induced current in the loop and we can find the rate of Joule heating using $P = I^2R$.

(*a*) Apply Faraday's law to express the induced emf in the loop in terms of the rate of change of the magnetic field:

$$|\mathcal{E}| = \frac{d\phi_{\mathrm{m}}}{dt} = \frac{d}{dt}(AB) = A\frac{dB}{dt} = \pi R^2\frac{dB}{dt}$$

Substitute numerical values and evaluate $|\mathcal{E}|$:

$$|\mathcal{E}| = \pi(0.0500\,\mathrm{m})^2(40.0\,\mathrm{mT/s}) = 0.3142\,\mathrm{mV} = \boxed{0.314\,\mathrm{mV}}$$

(*b*) Using Ohm's law, relate the induced current to the induced voltage and the resistance of the loop and evaluate *I*:

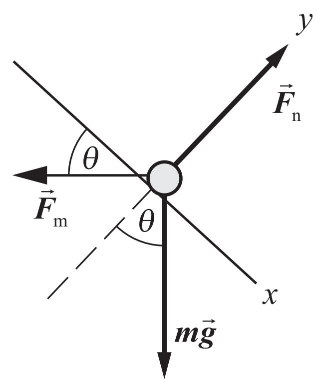
$$I = \frac{\mathcal{E}}{R} = \frac{0.3142\,\mathrm{mV}}{0.400\,\Omega} = 0.7854\,\mathrm{mA} = \boxed{0.785\,\mathrm{mA}}$$

(*c*) Express the rate at which power is dissipated in a conductor in terms of the induced current and the resistance of the loop and evaluate *P*:

$$P = I^2R = (0.7854\,\mathrm{mA})^2(0.400\,\Omega) = \boxed{0.247\,\mu\mathrm{W}}$$

43 •• In Figure 28-48, a conducting rod that has a mass *m* and a negligible resistance is free to slide without friction along two parallel frictionless rails that have negligible resistances separated by a distance ℓ and connected by a resistance *R*. The rails are attached to a long inclined plane that makes an angle θ with the horizontal. There is a magnetic field directed upward as shown. (*a*) Show that there is a retarding force directed up the incline given by $F = \left(B^2\ell^2 v\cos^2\theta\right)/R$. (*b*) Show that the terminal speed of the rod is $v_{\mathrm{t}} = (mgR\sin\theta)/\left(B^2\ell^2\cos^2\theta\right)$.

Picture the Problem The free-body diagram shows the forces acting on the rod as it slides down the inclined plane. The retarding force is the component of F_{m} acting up the incline, i.e., in the $-x$ direction. We can express F_{m} using the expression for the force acting on a conductor moving in a magnetic field. Recognizing that only the horizontal component of the rod's velocity $\vec{v}$ produces an induced emf, we can apply the expression for a motional emf in conjunction with Ohm's law to find the induced current in the rod. In Part (*b*) we can apply Newton's second law to obtain an expression for dv/dt and set this expression equal to zero to obtain v_{t}.



(*a*) Express the retarding force acting on the rod:

$$F = F_m \cos\theta \qquad (1)$$

where

$$F_m = I\ell B$$

and I is the current induced in the rod as a consequence of its motion in the magnetic field.

Express the induced emf due to the motion of the rod in the magnetic field:

$$\mathcal{E} = B\ell v\cos\theta$$

Using Ohm's law, relate the current I in the circuit to the induced emf:

$$I = \frac{\mathcal{E}}{R} = \frac{B\ell v\cos\theta}{R}$$

Substitute in equation (1) to obtain:

$$F = \left(\frac{B\ell v\cos\theta}{R}\right)\ell B\cos\theta = \boxed{\left(B^2\ell^2 v\cos^2\theta\right)/R}$$

(*b*) Apply $\sum F_x = ma_x$ to the rod:

$$mg\sin\theta - \frac{B^2\ell^2 v}{R}\cos^2\theta = m\frac{dv}{dt}$$

and

$$\frac{dv}{dt} = g\sin\theta - \frac{B^2\ell^2 v}{mR}\cos^2\theta$$

When the rod reaches its terminal speed v_t, $dv/dt = 0$:

$$0 = g\sin\theta - \frac{B^2\ell^2 v_t}{mR}\cos^2\theta$$

Solve for v_t to obtain:

$$v_t = \boxed{(mgR\sin\theta)/\left(B^2\ell^2\cos^2\theta\right)}$$

44 ••• A conducting rod of length ℓ rotates at constant angular speed ω about one end, in a plane perpendicular to a uniform magnetic field B (Figure 28-49). (*a*) Show that the potential difference between the ends of the rod is $\frac{1}{2}\ell^2\theta$. (*b*) Let the angle θ between the rotating rod and the dashed line be given by $\theta = \omega t$. Show that the area of the pie-shaped region swept out by the rod during time t is $\frac{1}{2}\ell^2\theta$. (*c*) Compute the flux ϕ_m through this area, and apply $\mathcal{E} = -d\phi_m/dt$ (Faraday's law) to show that the motional emf is given by $\frac{1}{2}B\omega\ell^2$.

Picture the Problem We can use $\vec{F} = q\vec{v} \times \vec{B}$ to express the magnetic force acting on the moving charged body. Expressing the emf induced in a segment of the rod of length dr and integrating this expression over the length of the rod will lead us to an expression for the induced emf.

(*a*) Use the motional emf equation to express the emf induced in a segment of the rod of length dr and at a distance r from the pivot:

$$d\mathcal{E} = Brdv = Br\omega dr$$

Integrate this expression from $r = 0$ to $r = \ell$ to obtain:

$$\int_0^{\mathcal{E}} d\mathcal{E} = B\omega\int_0^{\ell} rdr \Rightarrow \mathcal{E} = \boxed{\tfrac{1}{2}B\omega\ell^2}$$

(*b*) Using Faraday's law, relate the induced emf to the rate at which the flux changes:

$$|\mathcal{E}| = \frac{d\phi_m}{dt}$$

Express the area dA, for any value of θ, between r and $r + dr$:

$$dA = r\theta dr$$

Integrate from $r = 0$ to $r = \ell$ to obtain:

$$A = \theta\int_0^{\ell} rdr = \boxed{\tfrac{1}{2}\theta\ell^2}$$

(*c*) Using its definition, express the magnetic flux through this area:

$$\phi_m = BA = \boxed{\tfrac{1}{2}B\ell^2\theta}$$

Differentiate ϕ_m with respect to time to obtain:

$$|\mathcal{E}| = \frac{d}{dt}\left[\tfrac{1}{2}B\ell^2\theta\right] = \tfrac{1}{2}B\ell^2\frac{d\theta}{dt} = \boxed{\tfrac{1}{2}B\ell^2\omega}$$

45 • **[SSM]** A 2.00-cm by 1.50-cm rectangular coil has 300 turns and rotates in a region that has a magnetic field of 0.400 T. (*a*) What is the maximum emf generated when the coil rotates at 60 rev/s? (*b*) What must its angular speed be to generate a maximum emf of 110 V?

Picture the Problem We can use the relationship $\mathcal{E}_{max} = 2\pi NBAf$ to relate the maximum emf generated to the area of the coil, the number of turns of the coil, the magnetic field in which the coil is rotating, and the angular speed at which it rotates.

(*a*) Relate the induced emf to the magnetic field in which the coil is rotating:

$$\mathcal{E}_{max} = NBA\omega = 2\pi NBAf \qquad (1)$$

Substitute numerical values and evaluate $\mathcal{E}_{max}$:

$$\mathcal{E}_{max} = 2\pi(300)(0.400\,\mathrm{T})(2.00\times10^{-2}\,\mathrm{m})(1.50\times10^{-2}\,\mathrm{m})(60\,\mathrm{s}^{-1}) = \boxed{14\,\mathrm{V}}$$

(*b*) Solve equation (1) for *f*:

$$f = \frac{\mathcal{E}_{max}}{2\pi NBA}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{110\,\mathrm{V}}{2\pi(300)(0.400\,\mathrm{T})(2.00\times10^{-2}\,\mathrm{m})(1.50\times10^{-2}\,\mathrm{m})} = \boxed{486\,\mathrm{rev/s}}$$

46 • The coil of Problem 45 rotates at 60 rev/s in a magnetic field. If the maximum emf generated by the coil is 24 V, what is the magnitude of the magnetic field?

Picture the Problem We can use the relationship $\mathcal{E}_{max} = NBA\omega$ to relate the maximum emf generated to the area of the coil, the number of turns of the coil, the magnitude of the magnetic field in which the coil is rotating, and the angular speed at which it rotates.

Relate the induced emf to the magnetic field in which the coil is rotating:

$$\mathcal{E}_{max} = NBA\omega \Rightarrow B = \frac{\mathcal{E}_{max}}{NA\omega}$$

Substitute numerical values and evaluate B:

$$B=\frac{24\,\text{V}}{2\pi(300)\left(2.00\times10^{-2}\text{ m}\right)\left(1.50\times10^{-2}\text{ m}\right)(60\text{ rev/s})}=\boxed{0.71\,\text{T}}$$

Inductance

47 • When the current in an 8.00-H coil is equal to 3.00 A and is increasing at 200 A/s, find (*a*) the magnetic flux through the coil and (*b*) the induced emf in the coil.

Picture the Problem We can use $\phi_\text{m}=LI$ to find the magnetic flux through the coil. We can apply Faraday's law to find the induced emf in the coil.

(*a*) The magnetic flux through the coil is the product of the self-inductance of the coil and the current it is carrying:

$$\phi_\text{m}=LI$$

When the current is 3.00 A:

$$\phi_\text{m}=(8.00\,\text{H})(3.00\,\text{A})=\boxed{24.0\,\text{Wb}}$$

(*b*) Use Faraday's law to relate $\mathcal{E}$, L, and dI/dt:

$$\mathcal{E}=-L\frac{dI}{dt}$$

Substitute numerical values and evaluate $\mathcal{E}$:

$$\mathcal{E}=-(8.00\,\text{H})(200\,\text{A/s})=\boxed{-1.60\,\text{kV}}$$

48 •• A 300-turn solenoid has a radius equal to 2.00 cm; a length equal to 25.0 cm, and a 1000-turn solenoid has a radius equal to 5.00 cm and is also 25.0-cm long. The two solenoids are coaxial, with one nested completely inside the other. What is their mutual inductance?

Picture the Problem We can find the mutual inductance of the two coaxial solenoids using $M_{2,1}=\dfrac{\phi_{\text{m}2}}{I_1}=\mu_0 n_2 n_1 \ell \pi r_1^2$.

Substitute numerical values and evaluate $M_{2,1}$:

$$M_{2,1}=\left(4\pi\times10^{-7}\text{ N/A}^2\right)\left(\frac{300}{0.250\,\text{m}}\right)\left(\frac{1000}{0.250\,\text{m}}\right)(0.250\,\text{m})\pi(0.0200\,\text{m})^2=\boxed{1.89\,\text{mH}}$$

49 •• **[SSM]** An insulated wire that has a resistance of 18.0 Ω/m and a length of 9.00 m will be used to construct a resistor. First, the wire is bent in half and then the doubled wire is wound on a cylindrical form (Figure 28-50) to create a 25.0-cm-long helix that has a diameter equal to 2.00 cm. Find both the resistance and the inductance of this wire-wound resistor.

Picture the Problem Note that the current in the two parts of the wire is in opposite directions. Consequently, the total flux in the coil is zero. We can find the resistance of the wire-wound resistor from the length of wire used and the resistance per unit length.

Because the total flux in the coil is zero:

$$L = \boxed{0}$$

Express the total resistance of the wire:

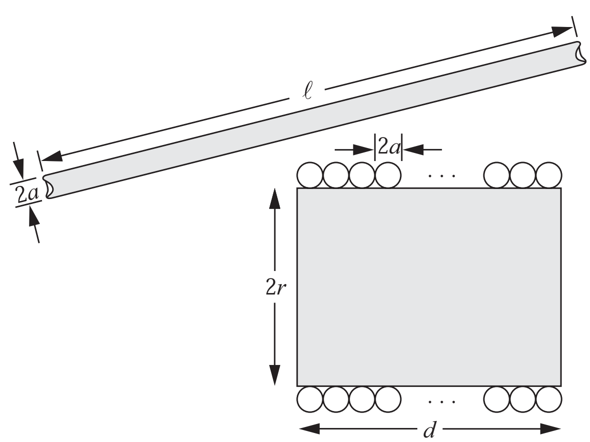
$$R = \left(18.0\frac{\Omega}{\text{m}}\right)L$$

Substitute numerical values and evaluate R:

$$R = \left(18.0\frac{\Omega}{\text{m}}\right)(9.00\,\text{m}) = \boxed{162\,\Omega}$$

50 •• You are given a length ℓ of wire that has radius a and are told to wind it into an inductor in the shape of a helix that has a circular cross section of radius r. The windings are to be as close together as possible without overlapping. Show that the self-inductance of this inductor is $L = \frac{1}{4}\mu_0 r\ell/a$.

Picture the Problem The wire of length ℓ and radius a is shown in the diagram, as is the inductor constructed with this wire and whose inductance L is to be found. We can use the equation for the self-inductance of a cylindrical inductor to derive an expression for L.



The self-inductance of an inductor with length d, cross-sectional area A, and number of turns per unit length n is:

$$L = \mu_0 n^2 A d \qquad (1)$$

The number of turns N is given by:

$$N = \frac{d}{2a} \Rightarrow n = \frac{N}{d} = \frac{1}{2a}$$

Assuming that $a << r$, the length of the wire ℓ is related to N and r:

$$\ell = N(2\pi r) = \left(\frac{d}{2a}\right) 2\pi r = \frac{\pi r}{a} d$$

Solving for d yields:

$$d = \frac{a\ell}{\pi r}$$

Substitute for d, A, and n in equation (1) to obtain:

$$L = \mu_0 \left(\frac{1}{2a}\right)^2 \left(\pi r^2\right)\left(\frac{a\ell}{\pi r}\right) = \boxed{\tfrac{1}{4}\mu_0 r\ell/a}$$

51 • Using the result of Problem 50, calculate the self-inductance of an inductor wound from 10 cm of wire that has a diameter of 1.0 mm into a coil that has a radius of 0.25 cm.

Picture the Problem We can substitute numerical values in the expression derived in Problem 50to find the self-inductance of the inductor.

From Problem 50 we have:

$$L = \frac{\mu_0 r d}{4a}$$

Substitute numerical values and evaluate L:

$$L = \frac{\left(4\pi \times 10^{-7}\ \text{N/A}^2\right)(0.25\,\text{cm})(10\,\text{cm})}{4(0.50\,\text{mm})} = \boxed{0.16\,\mu\text{H}}$$

52 ••• In Figure 28-51, circuit 2 has a total resistance of 300 Ω. After switch S is closed, the current in circuit 1 increases—reaching a value of 5.00 A after a long time. A charge of 200 μC passes through the galvanometer in circuit 2 during the time that the current in circuit 1 is increasing. What is the mutual inductance between the two coils?

Picture the Problem We can apply Kirchhoff's loop rule to the galvanometer circuit to relate the potential difference across L_2 to the potential difference across R_2. Integration of this equation over time will yield an equation that relates the mutual inductance between the two coils to the steady-state current in circuit 1 and the charge that flows through the galvanometer.

Apply Kirchhoff's loop rule to the galvanometer circuit:

$$M\frac{dI_1}{dt}+L_2\frac{dI_2}{dt}-R_2I_2=0$$

or

$$MdI_1+L_2dI_2-R_2I_2dt=0$$

Integrate each term from $t = 0$ to $t = \infty$:

$$M\int_0^\infty dI_1+L_2\int_0^\infty dI_2-R_2\int_0^\infty I_2dt=0$$

and

$$MI_{1\infty}+L_2I_{2\infty}-R_2Q=0$$

Because $I_{2\infty} = 0$:

$$MI_{1\infty}-R_2Q=0\Rightarrow M=\frac{R_2Q}{I_{1\infty}}$$

Substitute numerical values and evaluate M:

$$M=\frac{(300\,\Omega)(2.00\times10^{-4}\text{ C})}{5.00\text{ A}}=\boxed{12.0\text{ mH}}$$

53 ••• **[SSM]** Show that the inductance of a toroid of rectangular cross section, as shown in Figure 28-52 is given by $L=\frac{\mu_0N^2H\ln(b/a)}{2\pi}$ where N is the total number of turns, a is the inside radius, b is the outside radius, and H is the height of the toroid.

Picture the Problem We can use Ampere's law to express the magnetic field inside the rectangular toroid and the definition of magnetic flux to express ϕ_m through the toroid. We can then use the definition of self-inductance of a solenoid to express L.

Using the definition of the self-inductance of a solenoid, express L in terms of ϕ_m, N, and I:

$$L=\frac{N\phi_m}{I} \quad (1)$$

Apply Ampere's law to a closed path of radius $a < r < b$:

$$\oint_C \vec{B}\cdot d\vec{\ell}=B2\pi r=\mu_0I_C$$

or, because $I_C = NI$,

$$B2\pi r=\mu_0NI\Rightarrow B=\frac{\mu_0NI}{2\pi r}$$

Express the flux in a strip of height H and width dr:

$$d\phi_m=BHdr$$

Substituting for B yields:

$$d\phi_{\mathrm{m}} = \frac{\mu_0 NIH}{2\pi r}dr$$

Integrate $d\phi_{\mathrm{m}}$ from $r = a$ to $r = b$ to obtain:

$$\phi_{\mathrm{m}} = \frac{\mu_0 NIH}{2\pi}\int_a^b \frac{dr}{r} = \frac{\mu_0 NIH}{2\pi}\ln\left(\frac{b}{a}\right)$$

Substitute for ϕ_{m} in equation (1) and simplify to obtain:

$$L = \boxed{\frac{\mu_0 N^2 H}{2\pi}\ln\left(\frac{b}{a}\right)}$$

Magnetic Energy

54 • A coil that has a self-inductance of 2.00 H and a resistance of 12.0 Ω is connected to an ideal 24.0-V battery. (*a*) What is the steady-state current? (*b*) How much energy is stored in the inductor when the steady-state current is established?

Picture the Problem The current in an *LR* circuit, as a function of time, is given by $I = I_{\mathrm{f}}\left(1 - e^{-t/\tau}\right)$, where $I_{\mathrm{f}} = \varepsilon_0/R$ and $\tau = L/R$. The energy stored in the inductor under steady-state conditions is stored in its magnetic field and is given by $U_{\mathrm{m}} = \frac{1}{2}LI_{\mathrm{f}}^2$.

(*a*) The final current is the quotient of the emf of the battery and the resistance of the coil:

$$I_{\mathrm{f}} = \frac{\mathcal{E}_0}{R} = \frac{24.0\,\mathrm{V}}{12.0\,\Omega} = \boxed{2.00\,\mathrm{A}}$$

(*b*) The energy stored in the inductor is:

$$U_{\mathrm{m}} = \tfrac{1}{2}LI_{\mathrm{f}}^2 = \tfrac{1}{2}(2.00\,\mathrm{H})(2.00\,\mathrm{A})^2 = \boxed{4.00\,\mathrm{J}}$$

55 • **[SSM]** In a plane electromagnetic wave, the magnitudes of the electric fields and magnetic fields are related by $E = cB$, where $c = 1\big/\sqrt{\epsilon_0\,\mu_0}$ is the speed of light. Show that when $E = cB$ the electric and the magnetic energy densities are equal.

Picture the Problem We can examine the ratio of u_{m} to u_{E} with $E = cB$ and $c = 1\big/\sqrt{\epsilon_0\,\mu_0}$ to show that the electric and magnetic energy densities are equal.

Express the ratio of the energy density in the magnetic field to the energy density in the electric field:

$$\frac{u_{\mathrm{m}}}{u_{\mathrm{E}}} = \frac{\dfrac{B^2}{2\mu_0}}{\frac{1}{2}\epsilon_0 E^2} = \frac{B^2}{\mu_0\,\epsilon_0\,E^2}$$

Because $E = cB$:

$$\frac{u_m}{u_E} = \frac{B^2}{\mu_0 \in_0 c^2 B^2} = \frac{1}{\mu_0 \in_0 c^2}$$

Substituting for c^2 and simplifying yields:

$$\frac{u_m}{u_E} = \frac{\mu_0 \in_0}{\mu_0 \in_0} = 1 \Rightarrow u_m = \boxed{u_E}$$

56 •• A 2000-turn solenoid has a cross-sectional area equal to 4.0 cm^2 and length equal to 30 cm. The solenoid carries a current of 4.0 A. (*a*) Calculate the magnetic energy stored in the solenoid using $U = \frac{1}{2}LI^2$, where $L = \mu_0 n^2 A\ell$. (*b*) Divide your answer in Part (*a*) by the volume of the region inside the solenoid to find the magnetic energy per unit volume in the solenoid. (*c*) Check your Part (*b*) result by computing the magnetic energy density from $\mu_m = B^2/2\mu_0$ where $B = \mu_0 nI$.

Picture the Problem We can use $L = \mu_0 n^2 A\ell$ to find the inductance of the solenoid and $B = \mu_0 nI$ to find the magnetic field inside it.

(*a*) Express the magnetic energy stored in the solenoid:

$$U_m = \tfrac{1}{2}LI^2$$

Relate the inductance of the solenoid to its dimensions and properties:

$$L = \mu_0 n^2 A\ell$$

Substitute for L to obtain:

$$U_m = \tfrac{1}{2}\mu_0 n^2 A\ell I^2$$

Substitute numerical values and evaluate U_m:

$$U_m = \tfrac{1}{2}\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(\frac{2000}{0.30\,\text{m}}\right)^2 \times\left(4.0\times10^{-4}\ \text{m}^2\right)(0.30\,\text{m})(4.0\,\text{A})^2$$

$$= 53.6\,\text{mJ} = \boxed{54\,\text{mJ}}$$

(*b*) The magnetic energy per unit volume in the solenoid is:

$$\frac{U_m}{V} = \frac{U_m}{A\ell} = \frac{53.6\,\text{mJ}}{\left(4.0\times10^{-4}\ \text{m}^2\right)(0.30\,\text{m})} = \boxed{0.45\,\text{kJ/m}^3}$$

(*c*) The magnetic energy density in the solenoid is given by:

$$u_m = \frac{B^2}{2\mu_0}$$

Substituting for B and simplifying yields:

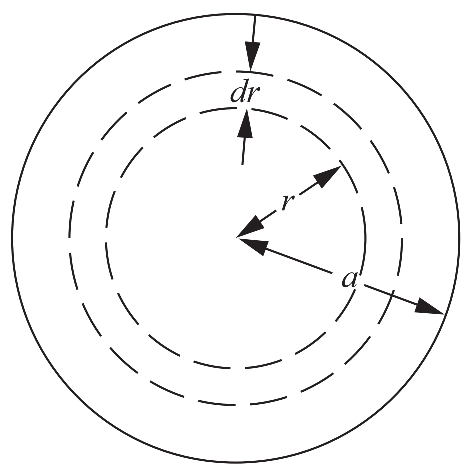
$$u_{\mathrm{m}} = \frac{(\mu_0 nI)^2}{2\mu_0} = \frac{\left(\mu_0 \frac{N}{\ell} I\right)^2}{2\mu_0} = \frac{\mu_0 N^2 I^2}{2\ell^2}$$

Substitute numerical values and evaluate u_{m}:

$$u_{\mathrm{m}} = \frac{(4\pi \times 10^{-7}\ \mathrm{N/A^2})(2000)^2(4.0\ \mathrm{A})^2}{2(0.30\ \mathrm{m})^2} = \boxed{0.45\ \mathrm{kJ/m^3}}$$

57 •• A long cylindrical wire has a radius equal to 2.0 cm and carries a current of 80 A uniformly distributed over its cross-sectional area. Find the magnetic energy per unit length within the wire.

Picture the Problem Consider a cylindrical annulus of thickness dr at a radius $r < a$. We can use its definition to express the total magnetic energy dU_{m} inside the cylindrical annulus and divide both sides of this expression by the length of the wire to express the magnetic energy per unit length dU'_m. Integration of this expression will give us the magnetic energy per unit length within the wire.



Express the magnetic energy within the cylindrical annulus:

$$dU_{\mathrm{m}} = \frac{B^2}{2\mu_0} V_{\mathrm{annulus}} = \frac{B^2}{2\mu_0} 2\pi r \ell dr = \frac{B^2}{\mu_0} \pi r \ell dr$$

Divide both sides of the equation by ℓ to express the magnetic energy per unit length dU'_m:

$$dU'_m = \frac{B^2}{\mu_0}\pi r dr \qquad (1)$$

Use Ampere's law to express the magnetic field inside the wire at a distance $r < a$ from its center:

$$2\pi rB = \mu_0 I_C \Rightarrow B = \frac{\mu_0 I_C}{2\pi r}$$

where I_C is the current inside the cylinder of radius r.

Because the current is uniformly distributed over the cross-sectional area of the wire:

$$\frac{I_C}{I} = \frac{\pi r^2}{\pi a^2} \Rightarrow I_C = \frac{r^2}{a^2}I$$

Substitute for I_C to obtain:

$$B = \frac{\mu_0 rI}{2\pi a^2}$$

Substituting for B in equation (1) and simplifying yields:

$$dU'_m = \frac{\left(\frac{\mu_0 rI}{2\pi a^2}\right)^2}{\mu_0}\pi r dr = \frac{\mu_0 I^2}{4\pi a^4}r^3 dr$$

Integrate dU'_m from $r = 0$ to $r = a$ to obtain:

$$U'_m = \frac{\mu_0 I^2}{4\pi a^4}\int_0^a r^3 dr = \frac{\mu_0 I^2}{4\pi a^4}\cdot\frac{a^4}{4} = \frac{\mu_0 I^2}{16\pi}$$

Substitute numerical values and evaluate U'_m:

$$U'_m = \frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(80\ \text{A}\right)^2}{16\pi} = \boxed{0.16\ \text{mJ/m}}$$

Remarks: Note that the magnetic energy per unit length is independent of the radius of the cylinder and depends only on the total current.

58 •• A toroid that has a mean radius equal to 25.0 cm and a circular loops with radii equal to 2.00 cm is wound with a superconducting wire. The wire has a length equal to 1000 m and carries a current of 400 A. (*a*) What is the number of turns of the wire? (*b*) What is the magnetic field strength and magnetic energy density at the mean radius? (*c*) Estimate the total energy stored in this toroid by assuming that the energy density is uniformly distributed in the region inside the toroid.

Picture the Problem We can find the number of turns on the coil from the length of the superconducting wire and the cross-sectional radius of the coil. We can use $B=(\mu_0 NI)/(2\pi r_{\text{mean}})$ to find the magnetic field at the mean radius. We can find the energy density in the magnetic field from $u_{\text{m}}=B^2/(2\mu_0)$ and the total energy stored in the toroid by multiplying u_{m} by the volume of the toroid.

(*a*) Express the number of turns in terms of the length of the wire L and length required per turn $2\pi r$:

$$N=\frac{L}{2\pi r}$$

Substitute numerical values and evaluate N:

$$N=\frac{1000\,\text{m}}{2\pi(0.0200\,\text{m})}=7958$$
$$=\boxed{7.96\times10^3}$$

(*b*) B inside a tightly wound toroid or radius r is given by:

$$B=\frac{\mu_0 NI}{2\pi r}$$

Substitute numerical values and evaluate the magnetic field at the mean radius:

$$B=\frac{(4\pi\times10^{-7}\,\text{N/A}^2)(7958)(400\,\text{A})}{2\pi(0.250\,\text{m})}$$
$$=2.547\,\text{T}=\boxed{2.55\,\text{T}}$$

The energy density in the magnetic field is given by:

$$u_{\text{m}}=\frac{B^2}{2\mu_0}$$

Substitute numerical values and evaluate u_{m}:

$$u_{\text{m}}=\frac{(2.547\,\text{T})^2}{2(4\pi\times10^{-7}\,\text{N/A}^2)}=2.580\,\text{MJ/m}^3$$
$$=\boxed{2.58\,\text{MJ/m}^3}$$

(*c*) Relate the total energy stored in the toroid to the energy density in its magnetic field and the volume of the toroid:

$$U_{\text{m}}=u_{\text{m}}V_{\text{toroid}}$$

Think of the toroid as a cylinder of radius r and height $2\pi r_{\text{mean}}$ to obtain:

$$V_{\text{toroid}}=\pi r^2(2\pi r_{\text{mean}})=2\pi^2 r^2 r_{\text{mean}}$$

Substitute for V_{toroid} to obtain:

$$U_{\text{m}}=2\pi^2 r^2 r_{\text{mean}} u_{\text{m}}$$

Substitute numerical values and evaluate U_m:

$$U_m = 2\pi^2(0.0200\,\text{m})^2(0.250\,\text{m})(2.580\,\text{MJ/m}^3) = \boxed{5.09\,\text{kJ}}$$

RL Circuits

59 • [SSM] A circuit consists of a coil that has a resistance equal to 8.00 Ω and a self-inductance equal to 4.00 mH, an open switch and an ideal 100-V battery—all connected in series. At $t = 0$ the switch is closed. Find the current and its rate of change at times (*a*) $t = 0$, (*b*) $t = 0.100$ ms, (*c*) $t = 0.500$ ms, and (*d*) $t = 1.00$ ms.

Picture the Problem We can find the current using $I = I_f\left(1 - e^{-t/\tau}\right)$ where $I_f = \mathcal{E}_0/R$ and $\tau = L/R$ and its rate of change by differentiating this expression with respect to time.

Express the dependence of the current on I_f and τ:

$$I = I_f\left(1 - e^{-t/\tau}\right)$$

Evaluating I_f and τ yields:

$$I_f = \frac{\mathcal{E}_0}{R} = \frac{100\,\text{V}}{8.00\,\Omega} = 12.5\,\text{A}$$

and

$$\tau = \frac{L}{R} = \frac{4.00\,\text{mH}}{8.00\,\Omega} = 0.500\,\text{ms}$$

Substitute for I_f and τ to obtain:

$$I = (12.5\,\text{A})\left(1 - e^{-t/0.500\,\text{ms}}\right)$$

Express dI/dt:

$$\frac{dI}{dt} = (12.5\,\text{A})\left(-e^{-t/0.500\,\text{ms}}\right)\left(-2000\,\text{s}^{-1}\right)$$
$$= (25.0\,\text{kA/s})e^{-t/0.500\,\text{ms}}$$

(*a*) Evaluate I and dI/dt at $t = 0$:

$$I(0) = (12.5\,\text{A})\left(1 - e^0\right) = \boxed{0}$$

and

$$\left.\frac{dI}{dt}\right|_{t=0} = (25.0\,\text{kA/s})e^0 = \boxed{25.0\,\text{kA/s}}$$

(*b*) Evaluating I and dI/dt at $t = 0.100$ ms yields:

$$I(0.100\,\text{ms}) = (12.5\,\text{A})\left(1 - e^{-0.100\,\text{ms}/0.500\,\text{ms}}\right)$$
$$= \boxed{2.27\,\text{A}}$$

and

$$\left.\frac{dI}{dt}\right|_{t=0.500\text{ ms}} = (25.0\,\text{kA/s})e^{-0.100\text{ ms}/0.500\text{ ms}}$$
$$= \boxed{20.5\,\text{kA/s}}$$

(*c*) Evaluate I and dI/dt at $t = 0.500$ ms to obtain:

$$I(0.500\text{ ms}) = (12.5\,\text{A})\left(1 - e^{-0.500\text{ ms}/0.500\text{ ms}}\right)$$
$$= \boxed{7.90\,\text{A}}$$

and

$$\left.\frac{dI}{dt}\right|_{t=0.500\text{ ms}} = (25.0\,\text{kA/s})e^{-0.500\text{ ms}/0.500\text{ ms}}$$
$$= \boxed{9.20\,\text{kA/s}}$$

(*d*) Evaluating I and dI/dt at $t = 1.00$ ms yields:

$$I(1.00\text{ ms}) = (12.5\,\text{A})\left(1 - e^{-1.00\text{ ms}/0.500\text{ ms}}\right)$$
$$= \boxed{10.8\,\text{A}}$$

and

$$\left.\frac{dI}{dt}\right|_{t=1.00\text{ ms}} = (25.0\,\text{kA/s})e^{-1.00\text{ ms}/0.500\text{ ms}}$$
$$= \boxed{3.38\,\text{kA/s}}$$

60 • In the circuit shown in Figure 28-53, the throw of the make-before-break switch has been at contact *a* for a long time and the current in the 1.00 mH coil is equal to 2.00 A. At $t = 0$ the throw is quickly moved to contact *b*. The total resistance $R + r$ of the coil and the resistor is 10.0 Ω. Find the current when (*a*) $t = 0.500$ ms, and (*b*) $t = 10.0$ ms.

Picture the Problem We can find the current using $I(t) = I_0 e^{-t/\tau}$, where I_0 is the current at time $t = 0$ and $\tau = L/R$.

Express the current as a function of time:

$$I(t) = I_0 e^{-t/\tau} = (2.00\,\text{A})e^{-t/\tau}$$

Evaluating τ yields:

$$\tau = \frac{L}{R} = \frac{1.00\,\text{mH}}{10.0\,\Omega} = 0.100\,\text{ms}$$

Substitute for τ to obtain:

$$I(t) = (2.00\,\text{A})e^{-0.100\text{ ms}t}$$

(*a*) When $t = 0.500$ ms:

$$I(0.500\text{ ms}) = (2.00\,\text{A})e^{-0.500\text{ ms}/0.100\text{ ms}}$$
$$= \boxed{13.5\,\text{mA}}$$

(*b*) When $t = 10.0$ ms:

$$I(10.0\text{ ms}) = (2\text{ A})e^{-10.0\text{ ms}/0.100\text{ ms}} = (2.00\text{ A})e^{-100} = 7.44\times10^{-44}\text{ A} \approx \boxed{0}$$

61 •• [SSM] In the circuit shown in Figure 28-54, let $\mathcal{E}_0 = 12.0$ V, $R = 3.00\ \Omega$, and $L = 0.600$ H. The switch, which was initially open, is closed at time $t = 0$. At time $t = 0.500$ s, find (*a*) the rate at which the battery supplies energy, (*b*) the rate of Joule heating in the resistor, and (*c*) the rate at which energy is being stored in the inductor.

Picture the Problem We can find the current using $I = I_\text{f}\left(1-e^{-t/\tau}\right)$, where $I_\text{f} = \mathcal{E}_0/R,$ and $\tau = L/R,$ and its rate of change by differentiating this expression with respect to time.

Express the dependence of the current on I_f and τ:

$$I(t) = I_\text{f}\left(1-e^{-t/\tau}\right)$$

Evaluating I_f and τ yields:

$$I_\text{f} = \frac{\mathcal{E}_0}{R} = \frac{12.0\text{ V}}{3.00\ \Omega} = 4.00\text{ A}$$

and

$$\tau = \frac{L}{R} = \frac{0.600\text{ H}}{3.00\ \Omega} = 0.200\text{ s}$$

Substitute for I_f and τ to obtain:

$$I(t) = (4.00\text{ A})\left(1-e^{-t/0.200\text{ s}}\right)$$

Express dI/dt:

$$\frac{dI}{dt} = (4.00\text{ A})\left(-e^{-t/0.200\text{ s}}\right)\left(-5.00\text{ s}^{-1}\right) = (20.0\text{ A/s})e^{-t/0.200\text{ s}}$$

(*a*) The rate at which the battery supplies energy is given by:

$$P = I\mathcal{E}_0$$

Substituting for I and $\mathcal{E}_0$ yields:

$$P(t) = (4.00\text{ A})\left(1-e^{-t/0.200\text{s}}\right)(12.0\text{ V}) = (48.0\text{ W})\left(1-e^{-t/0.200\text{s}}\right)$$

The rate at which the battery supplies energy at $t = 0.500$ s is:

$$P(0.500\text{ s}) = (48.0\text{ W})\left(1-e^{-0.500/0.200\text{s}}\right) = \boxed{44.1\text{ W}}$$

(*b*) The rate of Joule heating is:

$$P_J = I^2 R$$

Substitute for *I* and *R* and simplify to obtain:

$$P_J = \left[(4.00\,\text{A})\left(1 - e^{-t/0.200\,\text{s}}\right)\right]^2 (3.00\,\Omega) = (48.0\,\text{W})\left(1 - e^{-t/0.200\,\text{s}}\right)^2$$

The rate of Joule heating at $t = 0.500$ s is:

$$P_J(0.500\,\text{s}) = (48.0\,\text{W})\left(1 - e^{-0.500\,\text{s}/0.200\,\text{s}}\right)^2 = \boxed{40.4\ \text{W}}$$

(*c*) Use the expression for the magnetic energy stored in an inductor to express the rate at which energy is being stored:

$$\frac{dU_L}{dt} = \frac{d}{dt}\left[\tfrac{1}{2} L I^2\right] = LI\frac{dI}{dt}$$

Substitute for *L, I,* and *dI*/*dt* to obtain:

$$\frac{dU_L}{dt} = (0.600\,\text{H})(4.00\,\text{A})\left(1 - e^{-t/0.200\,\text{s}}\right)(20.0\,\text{A/s})e^{-t/0.200\,\text{s}} = (48.0\,\text{W})\left(1 - e^{-t/0.200\,\text{s}}\right)e^{-t/0.200\,\text{s}}$$

Evaluate this expression for $t = 0.500$ s:

$$\left.\frac{dU_L}{dt}\right]_{t=0.500\,\text{s}} = (48.0\,\text{W})\left(1 - e^{-0.500\,\text{s}/0.200\,\text{s}}\right)e^{-0.500\,\text{s}/0.200\,\text{s}} = \boxed{3.62\ \text{W}}$$

Remarks: Note that, to a good approximation, $dU_L/dt = P - P_J$.

62 •• How many time constants must elapse before the current in an *RL* circuit (Figure 28-54) that is initially zero reaches (*a*) 90 percent, (*b*) 99 percent, and (*c*) 99.9 percent of its steady-state value?

Picture the Problem If the current is initially zero in an *LR* circuit, its value at some later time *t* is given by $I = I_f\left(1 - e^{-t/\tau}\right)$, where $I_f = \mathcal{E}_0/R$ and $\tau = L/R$ is the time constant for the circuit. We can find the number of time constants that must elapse before the current reaches any given fraction of its final value by solving this equation for t/τ.

Express the fraction of its final value to which the current has risen as a function of time:

$$\frac{I}{I_f} = 1 - e^{-t/\tau} \Rightarrow \frac{t}{\tau} = -\ln\left(1 - \frac{I}{I_f}\right)$$

(*a*) Evaluate t/τ for $I/I_f = 0.90$:

$$\left.\frac{t}{\tau}\right|_{90\%} = -\ln(1-0.90) = \boxed{2.3}$$

(*b*) Evaluate t/τ for $I/I_f = 0.99$:

$$\left.\frac{t}{\tau}\right|_{99\%} = -\ln(1-0.99) = \boxed{4.6}$$

(*c*) Evaluate t/τ for $I/I_f = 0.999$:

$$\left.\frac{t}{\tau}\right|_{99.9\%} = -\ln(1-0.999) = \boxed{6.91}$$

63 •• [SSM] A circuit consists of a 4.00-mH coil, a 150-Ω resistor, a 12.0-V ideal battery and an open switch—all connected in series. After the switch is closed: (*a*) What is the initial rate of increase of the current? (*b*) What is the rate of increase of the current when the current is equal to half its steady-state value? (*c*) What is the steady-state value of the current? (*d*) How long does it take for the current to reach 99 percent of its steady state value?

Picture the Problem If the current is initially zero in an *LR* circuit, its value at some later time *t* is given by $I = I_f\left(1-e^{-t/\tau}\right)$, where $I_f = \mathcal{E}_0/R$ and $\tau = L/R$ is the time constant for the circuit. We can find the rate of increase of the current by differentiating *I* with respect to time and the time for the current to reach any given fraction of its initial value by solving for *t*.

(*a*) Express the current in the circuit as a function of time:

$$I = \frac{\mathcal{E}_0}{R}\left(1-e^{-t/\tau}\right)$$

Express the initial rate of increase of the current by differentiating this expression with respect to time:

$$\frac{dI}{dt} = \frac{\mathcal{E}_0}{R}\frac{d}{dt}\left(1-e^{-t/\tau}\right) = \frac{\mathcal{E}_0}{R}\left(-e^{-t/\tau}\right)\left(-\frac{1}{\tau}\right) = \frac{\mathcal{E}_0}{\tau R}e^{-\frac{R}{L}t} = \frac{\mathcal{E}_0}{L}e^{-\frac{R}{L}t}$$

Evaluate dI/dt at $t = 0$ to obtain:

$$\left.\frac{dI}{dt}\right|_{t=0} = \frac{\mathcal{E}_0}{L}e^0 = \frac{12.0\,\text{V}}{4.00\,\text{mH}} = \boxed{3.00\,\text{kA/s}}$$

(*b*) When $I = 0.5I_f$:

$$0.5 = 1-e^{-t/\tau} \Rightarrow e^{-t/\tau} = 0.5$$

Evaluate dI/dt with $e^{-t/\tau}=0.5$ to obtain:

$$\left.\frac{dI}{dt}\right|_{e^{-t/\tau}=0.5}=0.5\frac{\mathcal{E}_0}{L}=0.5\left(\frac{12.0\,\text{V}}{4.00\,\text{mH}}\right)=\boxed{1.50\,\text{kA/s}}$$

(c) Calculate I_f from $\mathcal{E}_0$ and R:

$$I_\text{f}=\frac{\mathcal{E}_0}{R}=\frac{12.0\,\text{V}}{150\,\Omega}=\boxed{80.0\,\text{mA}}$$

(d) When $I = 0.99I_\text{f}$:

$$0.99=1-e^{-t/\tau}\Rightarrow e^{-t/\tau}=0.01$$

Solving for t and substituting for τ yields:

$$t=-\tau\ln(0.01)=-\frac{L}{R}\ln(0.01)$$

Substitute numerical values and evaluate t:

$$t=-\frac{4.00\,\text{mH}}{150\,\Omega}\ln(0.01)=\boxed{0.123\,\text{ms}}$$

64 •• A circuit consists of a large electromagnet that has an inductance of 50.0 H and a resistance of 8.00 Ω, a dc 250-V power source and an open switch—all connected in series. How long after the switch is closed is the current equal to (a) 10 A, and (b) 30 A.

Picture the Problem If the current is initially zero in an LR circuit, its value at some later time t is given by $I=I_\text{f}\left(1-e^{-t/\tau}\right)$, where $I_\text{f} = \mathcal{E}_0/R$ and $\tau = L/R$ is the time constant for the circuit. We can find the time for the current to reach any given value by solving this equation for t.

Evaluate I_f and τ:

$$I_\text{f}=\frac{\mathcal{E}_0}{R}=\frac{250\,\text{V}}{8.00\,\Omega}=31.25\,\text{A}$$

and

$$\tau=\frac{L}{R}=\frac{50.0\,\text{H}}{8.00\,\Omega}=6.25\,\text{s}$$

Solve $I=I_\text{f}\left(1-e^{-t/\tau}\right)$ for t:

$$t=-\tau\ln\left(1-\frac{I}{I_\text{f}}\right)$$

Substituting for τ and I_f yields:

$$t=-(6.25\,\text{s})\ln\left(1-\frac{I}{31.25\,\text{A}}\right)$$

(*a*) Evaluate *t* for *I* = 10 A:

$$t\big|_{10\,\text{A}} = -(6.25\,\text{s})\ln\left(1-\frac{10\,\text{A}}{31.25\,\text{A}}\right) = \boxed{2.4\,\text{s}}$$

(*b*) Evaluate *t* for *I* = 30 A:

$$t\big|_{30\,\text{A}} = -(6.25\,\text{s})\ln\left(1-\frac{30\,\text{A}}{31.25\,\text{A}}\right) = \boxed{20\,\text{s}}$$

65 •• [SSM] Given the circuit shown in Figure 28-55, assume that the inductor has negligible internal resistance and that the switch S has been closed for a long time so that a steady current exists in the inductor. (*a*) Find the battery current, the current in the 100 Ω resistor, and the current in the inductor. (*b*) Find the potential drop across the inductor immediately after the switch S is opened. (*c*) Using a **spreadsheet** program, make graphs of the current in the inductor and the potential drop across the inductor as functions of time for the period during which the switch is open.

Picture the Problem The self-induced emf in the inductor is proportional to the rate at which the current through it is changing. Under steady-state conditions, $dI/dt = 0$ and so the self-induced emf in the inductor is zero. We can use Kirchhoff's loop rule to obtain the current through and the voltage across the inductor as a function of time.

(*a*) Because, under steady-state conditions, the self-induced emf in the inductor is zero and because the inductor has negligible resistance, we can apply Kirchhoff's loop rule to the loop that includes the source, the 10-Ω resistor, and the 2-H inductor to find the current drawn from the battery and flowing through the inductor and the 10-Ω resistor:

$$10\,\text{V} - (10\,\Omega)I_{10-\Omega} = 0$$

Solving for $I_{10-\Omega}$ yields:

$$I_{10-\Omega} = I_{2-\text{H}} = \boxed{1.0\,\text{A}}$$

By applying Kirchhoff's junction rule at the junction between the resistors, we can conclude that:

$$I_{100\text{-}\Omega} = I_{\text{battery}} - I_{2\text{-H}} = \boxed{0}$$

(*b*) When the switch is opened, the current cannot immediately go to zero in the circuit because of the inductor. For a time, a current will circulate in the circuit loop between the inductor and the 100-Ω resistor. Because the current flowing through this circuit is initially 1 A, the voltage drop across the 100-Ω resistor is initially $\boxed{100\,\text{V.}}$ Conservation of energy (Kirchhoff's loop rule) requires that the voltage drop across the 2-H inductor is $V_{\text{2-H}} = \boxed{100\,\text{V.}}$

(*c*) Apply Kirchhoff's loop rule to the *RL* circuit to obtain:

$$L\frac{dI}{dt} + IR = 0$$

The solution to this differential equation is:

$$I(t) = I_0 e^{-\frac{R}{L}t} = I_0 e^{-\frac{t}{\tau}}$$

$$\text{where } \tau = \frac{L}{R} = \frac{2.0\,\text{H}}{100\,\Omega} = 0.020\,\text{s}$$

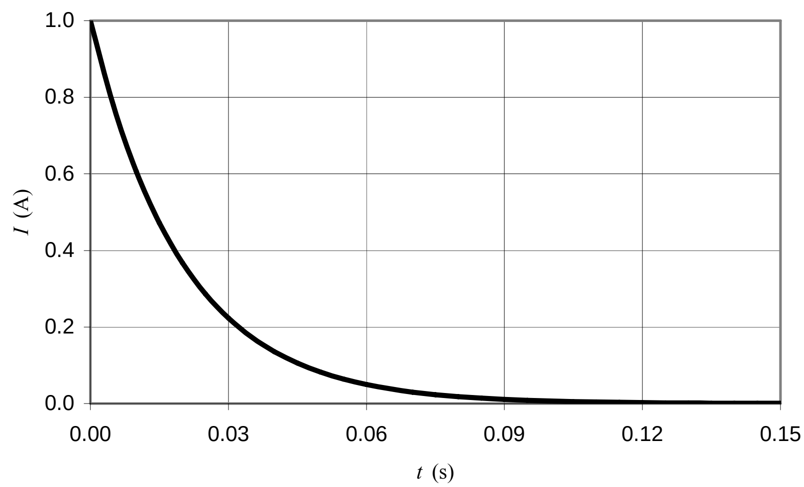
A spreadsheet program to generate the data for graphs of the current and the voltage across the inductor as functions of time is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	2.0	L
B2	100	R
B3	1	I_0
A6	0	t_0
B6	$B$3*EXP((–$B$2/$B$1)*A6)	$I_0 e^{-\frac{R}{L}t}$

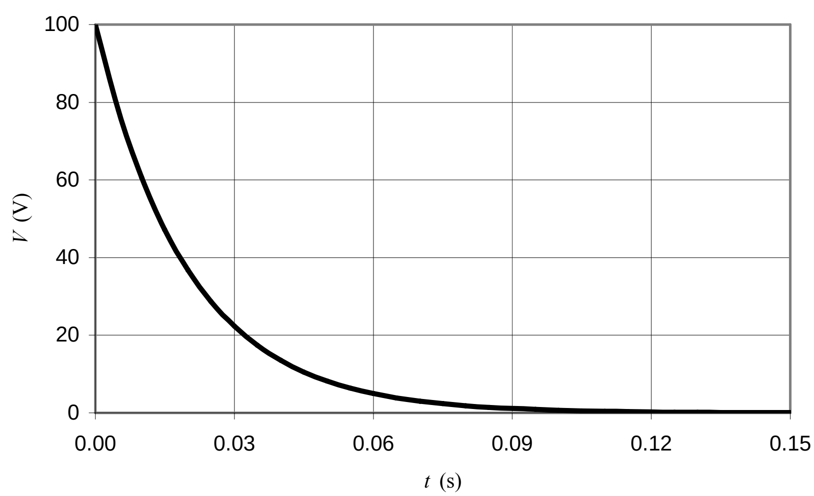
	A	B	C
1	L=	2	H
2	R=	100	ohms
3	I_0=	1	A
4			
5	t	$I(t)$	$V(t)$
6	0.000	1.00E+00	100.00
7	0.005	7.79E–01	77.88
8	0.010	6.07E–01	60.65
9	0.015	4.72E–01	47.24
10	0.020	3.68E–01	36.79
11	0.025	2.87E–01	28.65
12	0.030	2.23E–01	22.31

32	0.130	1.50E−03	0.15
33	0.135	1.17E−03	0.12
34	0.140	9.12E−04	0.09
35	0.145	7.10E−04	0.07
36	0.150	5.53E−04	0.06

The following graph of the current in the inductor as a function of time was plotted using the data in columns A and B of the spreadsheet program.



The following graph of the voltage across the inductor as a function of time was plotted using the data in columns A and C of the spreadsheet program.



66 •• Given the circuit shown in Figure 28-56, the inductor has negligible internal resistance and the switch S has been open for a long time. The switch is then closed. (*a*) Find the current in the battery, the current in the 100-Ω resistor, and the current in the inductor immediately after the switch is closed. (*b*) Find the

current in the battery, the current in the 100-Ω resistor, and the current in the inductor a long time after the switch is closed. After being closed for a long time the switch is now opened. (*c*) Find the current in the battery, the current in the 100-Ω resistor, and the current in the inductor immediately after the switch is opened. (*d*) Find the current in the battery, the current in the 100-Ω resistor, and the current in the inductor after the switch is opened for a long time.

Picture the Problem Let the current supplied by the battery be I_{battery}, the current through the inductor be I_L, and the current in the 100-Ω resistor be $I_{100\text{-}\Omega}$. (*a*) We simplify our calculations by using the fact that the current in an inductor cannot change abruptly. Thus, the current in the inductor must be zero just after the switch is closed, because the current is zero before the switch is closed. (*b*) When the current reaches its final value, *dI*/*dt* equals zero, and there is no potential drop across the inductor. The inductor thus acts like a short circuit; that is, the inductor acts like a wire with zero resistance. (*c*) Immediately after the switch is opened, the current in the inductor is the same as it was before. (*d*) A long time after the switch is opened, all the currents must be zero.

(*a*) The switch is just opened. The current through the inductor is zero, just as it was before the switch was closed. Apply the junction rule to relate I_{battery} and $I_{100\text{-}\Omega}$:

$$I_L = \boxed{0}$$

$$I_{\text{battery}} = I_{100-\Omega} + I_L \Rightarrow I_{\text{battery}} = I_{100-\Omega}$$

Apply Kirchhoff's loop rule to the loop on the right to obtain:

$$10.0\text{ V} - I_{\text{battery}}(10.0\,\Omega) - I_{100\text{-}\Omega}(100\,\Omega) = 0$$

or, because $I_{\text{battery}} = I_{100-\Omega}$,

$$10.0\text{ V} - I_{\text{battery}}(10.0\,\Omega) - I_{\text{battery}}(100\,\Omega) = 0$$

Solving for I_{battery} yields:

$$I_{\text{battery}} = I_{100\text{-}\Omega} = \frac{10.0\text{ V}}{10.0\,\Omega + 100\,\Omega} = \boxed{90.9\text{ mA}}$$

(*b*) After a long time, the currents are steady and the inductor acts like a short circuit, so the potential drop across the 100-Ω resistor is zero. Apply the loop rule to the loop to the right to obtain:

$$-(2.00\text{ H})\frac{dI_{\text{L}}}{dt} + I_{100-\Omega}(100\,\Omega) = 0$$

Because $\frac{dI_{\text{L}}}{dt}=0$:

$$I_{100-\Omega}(100\ \Omega)=0$$

and

$$I_{100-\Omega}=\boxed{0}$$

Apply the loop rule to the loop to the right to obtain:

$$10.0\ \text{V}-I_{\text{battery}}(10.0\ \text{V})-I_{100-\Omega}(100\ \Omega)=0$$

Because $I_{100-\Omega}=0$:

$$10.0\ \text{V}-I_{\text{battery}}(10.0\ \text{V})=0$$

and

$$I_{\text{battery}}=\boxed{1.00\ \text{A}}$$

Apply the junction rule to the three currents to obtain:

$$I_{\text{battery}}=I_L+I_{100-\Omega}\Rightarrow 1.00\ \text{A}=I_L+0$$

and so $I_L=\boxed{1.00\ \text{A}}$

(*c*) When the switch is reopened, I_1 *instantly* becomes zero. The current I_L in the inductor changes continuously, so at that instant I_L = 1.00 A. Apply the junction rule to obtain:

$$I_L=\boxed{1.00\ \text{A}},$$

$$I_{\text{battery}}=I_{100-\Omega}+I_L,$$

and

$$I_{100-\Omega}=I_{\text{battery}}-I_L$$

Substitute numerical values for I_{battery} and I_{L} and evaluate $I_{100\text{-}\Omega}$:

$$I_{100-\Omega}=0-1.00\ \text{A}=\boxed{-1.00\ \text{A}}$$

(*d*) A long time after the switch is opened, all the currents must be zero:

$$I_{\text{battery}}=I_L=I_{100-\Omega}=\boxed{0}$$

67 •• An inductor, two resistors, a make-before-break switch an a battery are connected as shown in Figure 28-57. The switch throw has been at contact *e* for a long time and the current in the inductor is 2.5 A. Then, at t = 0, the throw is quickly moved to contact *f*. During the next 45 ms the current in the inductor drops to 1.5 A. (*a*) What is the time constant for this circuit? (*b*) If the resistance *R* is equal to 0.40 Ω, what is the value of the inductance *L*?

Picture the Problem The current in an initially energized but source-free *RL* circuit is given by $I=I_0e^{-t/\tau}$. We can find τ from this equation and then use its definition to evaluate *L*.

(*a*) Express the current in the *RL* circuit as a function of time:

$$I = I_0 e^{-t/\tau} \Rightarrow \tau = -\frac{t}{\ln\left(\frac{I}{I_0}\right)}$$

Substitute numerical values and evaluate τ:

$$\tau = -\frac{45\,\text{ms}}{\ln\left(\frac{1.5\,\text{A}}{2.5\,\text{A}}\right)} = 88.1\,\text{ms} = \boxed{88\,\text{ms}}$$

(*b*) Using the definition of the inductive time constant, relate *L* to *R*:

$$L = \tau R$$

Substitute numerical values and evaluate *L*:

$$L = (88.1\,\text{ms})(0.40\,\Omega) = \boxed{35\,\text{mH}}$$

68 •• A circuit consists of a coil that has a self-inductance equal to 5.00 mH and an internal resistance equal to 15.0 Ω, an ideal 12.0-V battery and an open switch—all connected in series (Figure 28-58), At $t = 0$ the switch is closed. Find the time at which the rate at which energy is dissipated in the coil equals the rate at which magnetic energy is stored in the coil.

Picture the Problem If the current is initially zero in an *LR* circuit, its value at some later time *t* is given by $I = I_f\left(1 - e^{-t/\tau}\right)$, where $I_f = \mathcal{E}_0/R$ and $\tau = L/R$ is the time constant for the circuit. We can find the time at which the power dissipation in the resistor equals the rate at which magnetic energy is stored in the inductor by equating expressions for these rates and using the expression for *I* and its rate of change.

Express the rate at which magnetic energy is stored in the inductor:

$$\frac{dU_L}{dt} = \frac{d}{dt}\left[\tfrac{1}{2}LI^2\right] = LI\frac{dI}{dt}$$

Express the rate at which power is dissipated in the resistor:

$$P = I^2 R$$

Equate these expressions to obtain:

$$I^2 R = LI\frac{dI}{dt} \Rightarrow I = \tau\frac{dI}{dt} \qquad (1)$$

Express the current and its rate of change:

$$I = I_{\text{f}}\left(1 - e^{-t/\tau}\right)$$

and

$$\frac{dI}{dt} = I_{\text{f}}\frac{d}{dt}\left(1 - e^{-t/\tau}\right) = -I_{\text{f}}e^{-t/\tau}\left(-\frac{1}{\tau}\right)$$

$$= \frac{I_{\text{f}}}{\tau}e^{-t/\tau}$$

Substitute for dI/dt in equation (1) and simplify to obtain:

$$I_{\text{f}}\left(1 - e^{-t/\tau}\right) = \tau\left(\frac{I_{\text{f}}}{\tau}e^{-t/\tau}\right)$$

or

$$1 - e^{-t/\tau} = e^{-t/\tau} \Rightarrow 1 = 2e^{-t/\tau}$$

Solving for t and substituting for τ yields:

$$t = -\tau\ln\left(\tfrac{1}{2}\right) = -\frac{L}{R}\ln\left(\tfrac{1}{2}\right)$$

Substitute numerical values and evaluate t:

$$t = -\frac{5.00\text{ mH}}{15.0\,\Omega}\ln\left(\tfrac{1}{2}\right) = \boxed{231\,\mu\text{s}}$$

69 ••• [SSM] In the circuit shown in Figure 28-54, let $\mathcal{E}_0$ = 12.0 V, R = 3.00 Ω, and L = 0.600 H. The switch is closed at time t = 0. During the time from t = 0 to t = L/R, find (*a*) the amount of energy supplied by the battery, (*b*) the amount of energy dissipated in the resistor, and (*c*) the amount of energy delivered to the inductor. *Hint: Find the energy transfer rates as functions of time and integrate.*

Picture the Problem We can integrate $dE/dt = \mathcal{E}_0 I,$ where $I = I_{\text{f}}\left(1 - e^{-t/\tau}\right)$, to find the energy supplied by the battery, $dE_{\text{J}}/dt = I^2R$ to find the energy dissipated in the resistor, and $U_L(\tau) = \frac{1}{2}L(I(\tau))^2$ to express the energy that has been stored in the inductor when $t = L/R$.

(*a*) Express the rate at which energy is supplied by the battery:

$$\frac{dE}{dt} = \mathcal{E}_0 I$$

Express the current in the circuit as a function of time:

$$I = \frac{\mathcal{E}_0}{R}\left(1 - e^{-t/\tau}\right)$$

Substitute for I to obtain:

$$\frac{dE}{dt} = \frac{\mathcal{E}_0^2}{R}\left(1 - e^{-t/\tau}\right)$$

Separate variables and integrate from $t = 0$ to $t = \tau$ to obtain:

$$E = \frac{\mathcal{E}_0^2}{R}\int_0^{\tau}\left(1 - e^{-t/\tau}\right)dt = \frac{\mathcal{E}_0^2}{R}\left[\tau - \left(-\tau e^{-1} + \tau\right)\right] = \frac{\mathcal{E}_0^2}{R}\frac{\tau}{e} = \frac{\mathcal{E}_0^2 L}{R^2 e}$$

Substitute numerical values and evaluate E:

$$E = \frac{(12.0\,\text{V})^2(0.600\,\text{H})}{(3.00\,\Omega)^2 e} = \boxed{3.53\,\text{J}}$$

(b) Express the rate at which energy is being dissipated in the resistor:

$$\frac{dE_\text{J}}{dt} = I^2 R = \left[\frac{\mathcal{E}_0}{R}\left(1 - e^{-t/\tau}\right)\right]^2 R = \frac{\mathcal{E}_0^2}{R}\left(1 - 2e^{-t/\tau} + e^{-2t/\tau}\right)$$

Separate variables and integrate from $t = 0$ to $t = L/R$ to obtain:

$$E_\text{J} = \frac{\mathcal{E}_0^2}{R}\int_0^{L/R}\left(1 - 2e^{-t/\tau} + e^{-2t/\tau}\right)dt = \frac{\mathcal{E}_0^2}{R}\left(\frac{2\frac{L}{R}}{e} - \frac{\frac{L}{R}}{2} - \frac{\frac{L}{R}}{2e^2}\right) = \frac{\mathcal{E}_0^2 L}{R^2}\left(\frac{2}{e} - \frac{1}{2} - \frac{1}{2e^2}\right)$$

Substitute numerical values and evaluate E_J:

$$E_\text{J} = \frac{(12.0\,\text{V})^2(0.600\,\text{H})}{(3.00\,\Omega)^2}\left(\frac{2}{e} - \frac{1}{2} - \frac{1}{2e^2}\right) = \boxed{1.61\,\text{J}}$$

(c) Express the energy stored in the inductor when $t = \dfrac{L}{R}$:

$$U_L\left(\frac{L}{R}\right) = \tfrac{1}{2}L\left(I\left(\frac{L}{R}\right)\right) = \tfrac{1}{2}L\left(\frac{\mathcal{E}_0}{R}\left(1 - e^{-1}\right)\right)^2 = \frac{L\mathcal{E}_0^2}{2R^2}\left(1 - e^{-1}\right)^2$$

Substitute numerical values and evaluate U_L:

$$U_L\left(\frac{L}{R}\right)=\frac{(0.600\,\text{H})(12.0\,\text{V})^2}{2(3.00\,\Omega)^2}\left(1-e^{-1}\right)^2$$
$$=\boxed{1.92\,\text{J}}$$

Remarks: Note that, as we would expect from energy conservation, $\boldsymbol{E = E_J + E_L}$.

General Problems

70 • A 100-turn coil has a radius of 4.00 cm and a resistance of 25.0 Ω. (*a*) The coil is in a uniform magnetic field that is perpendicular to the plane of the coil. What rate of change of the magnetic field strength will induce a current of 4.00 A in the coil? (*b*) What rate of change of the magnetic field strength is required if the magnetic field makes an angle of 20° with the normal to the plane of the coil?

Picture the Problem We can apply Faraday's and Ohm's laws to obtain expressions for the induced emf that we can equate and solve for the rate at which the perpendicular magnetic field must change to induce a current of 4.00 A in the coil.

(*a*) Using Faraday's law, relate the induced emf in the coil to the changing magnetic flux:

$$|\mathcal{E}|=\frac{d\phi_{\text{m}}}{dt}=NA\frac{dB}{dt}$$

Using Ohm's law, relate the induced emf to the resistance of the coil and the current in it:

$$|\mathcal{E}|=IR$$

Equate these expressions and solve for dB/dt:

$$NA\frac{dB}{dt}=IR \Rightarrow \frac{dB}{dt}=\frac{IR}{NA}=\frac{IR}{N\pi r^2}$$

Substitute numerical values and evaluate dB/dt:

$$\frac{dB}{dt}=\frac{(4.00\,\text{A})(25.0\,\Omega)}{(100)\pi(0.0400\,\text{m})^2}=\boxed{199\,\text{T/s}}$$

(*b*) Using Faraday's law, relate the induced emf in the coil to the changing magnetic flux when the field makes an angle θ with respect to the normal to the coil area:

$$|\mathcal{E}|=\frac{d\phi_{\text{m}}}{dt}=\frac{d}{dt}\left(NA\vec{B}\cdot\hat{n}\right)$$
$$=NA\cos\theta\frac{dB}{dt}$$

Proceed as in (*a*) to obtain:

$$\frac{dB}{dt}=\frac{IR}{N\pi r^2\cos\theta}$$

Substitute numerical values and evaluate dB/dt:

$$\frac{dB}{dt}=\frac{(4.00\,\text{A})(25.0\,\Omega)}{(100)\pi(0.0400\,\text{m})^2\cos 20°}=\boxed{212\,\text{T/s}}$$

71 •• [SSM] Figure 28-59 shows a schematic drawing of an *ac generator*. The basic generator consists of a rectangular loop of dimensions *a* and *b* and has *N* turns connected to *slip rings*. The loop rotates (driven by a gasoline engine) at an angular speed of ω in a uniform magnetic field $\vec{B}$. (*a*) Show that the induced potential difference between the two slip rings is given by $\mathcal{E} = NBab\omega\sin\omega t$. (*b*) If $a = 2.00$ cm, $b = 4.00$ cm, $N = 250$, and $B = 0.200$ T, at what angular frequency ω must the coil rotate to generate an emf whose maximum value is 100V?

Picture the Problem (*a*) We can apply Faraday's law and the definition of magnetic flux to derive an expression for the induced emf in the coil (potential difference between the slip rings). In Part (*b*) we can solve the equation derived in Part (*a*) for ω and evaluate this expression under the given conditions.

(*a*) Use Faraday's law to express the induced emf:

$$\mathcal{E}=-\frac{d\phi_\text{m}(t)}{dt}$$

Using the definition of magnetic flux, relate the magnetic flux through the loop to its angular velocity:

$$\phi_\text{m}(t)=NBA\cos\omega t$$

Substitute for $\phi_\text{m}(t)$ to obtain:

$$\mathcal{E}=-\frac{d}{dt}[NBA\cos\omega t]=-NBab\omega(-\sin\omega t)=\boxed{NBab\omega\sin\omega t}$$

(*b*) Express the condition under which $\mathcal{E}=\mathcal{E}_\text{max}$:

$$\sin\omega t=1$$

and

$$\mathcal{E}_\text{max}=NBab\omega\Rightarrow\omega=\frac{\mathcal{E}_\text{max}}{NBab}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{100\,\text{V}}{(250)(0.200\,\text{T})(0.0200\,\text{m})(0.0400\,\text{m})} = \boxed{2.50\,\text{krad/s}}$$

72 •• Prior to 1960, magnetic field strengths were usually measured by a *rotating coil gaussmeter*. This device used a small multi-turn coil rotating at a high speed on an axis perpendicular to the magnetic field. This coil was connected to an ac voltmeter by means of slip rings, like those shown in Figure 28-61. In one specific design, the rotating coil has 400 turns and an area of 1.40 cm^2. The coil rotates at 180 rev/min. If the magnetic field strength is 0.450 T, find the maximum induced emf in the coil and the orientation of the normal to the plane of the coil relative to the field for which this maximum induced emf occurs.

Picture the Problem We can apply Faraday's law and the definition of magnetic flux to derive an expression for the induced emf in the rotating coil gaussmeter.

Use Faraday's law to express the induced emf:

$$\mathcal{E} = -\frac{d\phi_\text{m}}{dt}$$

Using the definition of magnetic flux, relate the magnetic flux through the loop to its angular velocity:

$$\phi_\text{m}(t) = NBA\cos\omega t$$

Substitute for $\phi_\text{m}(t)$ and simplify to obtain:

$$\begin{aligned}\mathcal{E} &= -\frac{d}{dt}\left[NBA\cos\omega t\right] \\ &= -NBA\omega(-\sin\omega t) \\ &= NBA\omega\sin\omega t = \mathcal{E}_\text{max}\sin\omega t\end{aligned}$$

where

$$\mathcal{E}_\text{max} = NBA\omega$$

Substitute numerical values and evaluate $\mathcal{E}_\text{max}$:

$$\mathcal{E}_\text{max} = (400)(0.450\,\text{T})(1.40\times10^{-4}\,\text{m}^2)\left(180\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right) = \boxed{0.475\,\text{V}}$$

The maximum induced emf occurs at the instant the normal to the plane of the coil is perpendicular to the magnetic field $\vec{B}$. At this instant, ϕ_m is zero, but $\mathcal{E}$ is a maximum.

73 •• Show that the equivalent self-inductance for two inductors that have self-inductances L_1 and L_2, and are connected in series is given by $L_{eq} = L_1 + L_2$ if there is no flux linkage between the two inductors. (Saying there is no flux linkage between them is equivalent to saying that the mutual inductance between them is zero.)

Picture the Problem We can use the equality of the currents in the inductors connected in series and the additive nature of the total induced emf across the inductors to show that the self-inductances are additive.

Relate the total induced emf $\mathcal{E}$ to the effective self-inductance L_{eq} and the rate at which the current is changing in the inductors:

$$\mathcal{E} = L_{eq}\frac{dI}{dt}$$

Because the inductors L_1 and L_2 are in series:

$$I_1 = I_2 = I \Rightarrow \frac{dI_1}{dt} = \frac{dI_2}{dt} = \frac{dI}{dt}$$

Express the total induced emf:

$$\mathcal{E} = \mathcal{E}_1 + \mathcal{E}_2 = L_1\frac{dI}{dt} + L_2\frac{dI}{dt} = (L_1 + L_2)\frac{dI}{dt}$$

Substitute in equation (1) and simplify to obtain:

$$L_{eq} = \boxed{L_1 + L_2}$$

74 •• Show that the equivalent self-inductance for two inductors that have self-inductances L_1 and L_2, and are connected in parallel is given by $\frac{1}{L_{eq}} = \frac{1}{L_1} + \frac{1}{L_2}$ if there is no flux linkage between the two inductors. (Saying there is no flux linkage between them is equivalent to saying that the mutual inductance between them is equal to zero.)

Picture the Problem We can use the common potential difference across the parallel combination of inductors and the fact that the current into the parallel combination is the sum of the currents through each inductor to find an expression of the equivalent self-inductance.

Define L_{eq} by:

$$L_{eq} = \frac{\mathcal{E}}{dI/dt} \Rightarrow \frac{dI}{dt} = \mathcal{E}\frac{1}{L_{eq}} \quad (1)$$

Relate the common potential difference across the inductors to their self-inductances and the rate at which the current is changing in each:

$$\mathcal{E}_1 = L_1 \frac{dI_1}{dt} \qquad (2)$$

and

$$\mathcal{E}_2 = L_2 \frac{dI_2}{dt} \qquad (3)$$

Because the current divides at the parallel junction:

$$I = I_1 + I_2 \Rightarrow \frac{dI}{dt} = \frac{dI_1}{dt} + \frac{dI_2}{dt}$$

Solve equations (2) and (3) for dI_1/dt and dI_2/dt and substitute to obtain:

$$\frac{dI}{dt} = \frac{\mathcal{E}_1}{L_1} + \frac{\mathcal{E}_2}{L_2}$$

Express the relationship between an emf $\mathcal{E}$ applied across the parallel combination of inductors and the emfs $\mathcal{E}_1$ and $\mathcal{E}_2$ across the individual inductors:

$$\mathcal{E} = \mathcal{E}_1 = \mathcal{E}_2$$

Substituting yields:

$$\frac{dI}{dt} = \frac{\mathcal{E}}{L_1} + \frac{\mathcal{E}}{L_2} = \mathcal{E}\left(\frac{1}{L_1} + \frac{1}{L_2}\right)$$

Substitute in equation (1) and solve for $1/L_{\text{eq}}$:

$$\frac{1}{L_{\text{eq}}} = \boxed{\frac{1}{L_1} + \frac{1}{L_2}}$$

75 •• A circuit consists of a 12V battery, a switch, and a light bulb—all connected in series. It is known that the light bulb requires a minimum current of 0.10 A in order to produce a visible glow. In this circuit, this particular bulb draws 2.0 W when the switch has been closed for a long time. Now, an inductor is put in series with the bulb and the rest of the circuit. If the light bulb begins to glow 3.5 ms after the switch is closed, how large is the self-inductance of the inductor? Ignore any heating time of the filament and assume the glow is observed as soon as the current in the filament reaches the 0.10 A threshold.

Picture the Problem We can use Equation 28-25 to express the current in the circuit as a function of time and the expression $P = \mathcal{E}^2/R$ for the rate at which energy is dissipated in the light bulb to express the resistance of the circuit.

Use Equation 28-25 to express the current in the RL circuit:

$$I(t) = I_0\left(1 - e^{-t/\tau}\right) = \frac{\mathcal{E}}{R}\left(1 - e^{-Rt/L}\right)$$

The resistance of the light bulb is related to the rate at which it dissipates energy:

$$P = \frac{\mathcal{E}^2}{R} \Rightarrow R = \frac{\mathcal{E}^2}{P}$$

Substitute for R and simplify to obtain:

$$I(t) = \frac{\mathcal{E}}{\frac{\mathcal{E}^2}{P}}\left(1 - e^{-\frac{V^2}{P}t/L}\right) = \frac{P}{\mathcal{E}}\left(1 - e^{-V^2t/PL}\right)$$

or, for $I(t) = I_{\min}$,

$$I_{\min} = \frac{P}{\mathcal{E}}\left(1 - e^{-V^2t/PL}\right)$$

Solving for L yields:

$$L = \frac{-\mathcal{E}^2 t}{P\ln\left(1 - \frac{\mathcal{E}I_{\min}}{P}\right)}$$

Substitute numerical values and evaluate L:

$$L = \frac{-(12\text{ V})^2(3.5\text{ ms})}{(2.0\text{ W})\ln\left(1 - \frac{(12\text{ V})(0.10\text{ A})}{2.0\text{ W}}\right)}$$

$$= \boxed{0.28\text{ H}}$$

76 •• Your friend decides to generate electrical power by rotating a 100 000-turn coil of wire around an axis in the plane of the coil and through its center The coil is perpendicular to Earth' magnetic field in a region where the field strength is equal to 0.300 G. The loops of the coil have a radius 25.0 cm, and the coil has negligible resistance. (*a*) If your friend turns the coil at a rate of 150 rev/s, what peak current will exist in a 1500-Ω resistor that is connected across the terminals the coil? (*b*) The average of the square of the current will equal half of the square of the peak current. What will be the average power delivered to the resistor? Is this an economical way to generate power? *HINT: Energy has to be expended to keep the coil rotating.*

Picture the Problem We can use Ohm's law to express the peak current in terms of the peak induced emf in the coil and the resistance of the resistor attached to the coil and Faraday's law to find the peak induced emf in the coil.

(*a*) Apply Ohm's law to the coil and external resistor to obtain:

$$I_{\text{peak}} = \frac{\mathcal{E}_{\max}}{R}$$

Appling Faraday's law yields:

$$\mathcal{E} = -\frac{d\phi_{\text{m}}}{dt} = -\frac{d}{dt}(NBA\cos\omega t)$$

$$= NBA\omega\sin\omega t = \mathcal{E}_{\max}\sin\omega t$$

where $\mathcal{E}_{\max} = NBA\omega$.

Substitute for $\mathcal{E}_{\max}$ to obtain:

$$I_{\text{peak}} = \frac{NBA\omega}{R} = \frac{NB\pi r^2(2\pi f)}{R} = \frac{2\pi^2 NBr^2 f}{R}$$

Substitute numerical values and evaluate I_{peak}:

$$I_{\text{peak}} = \frac{2\pi^2(10^5)\left(0.300\ \text{G}\times\frac{1\ \text{T}}{10^4\ \text{G}}\right)(0.250\ \text{m})^2\left(150\ \frac{\text{rev}}{\text{s}}\right)}{1500\ \Omega} = 370.11\ \text{mA}$$
$$= \boxed{370\ \text{mA}}$$

(*b*) The average power supplied is the power dissipated in Joule heat in the resistor:

$$P_{\text{av}} = \left(I^2\right)_{\text{av}} R = \tfrac{1}{2} I_{\text{peak}}^2 R$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}} = \tfrac{1}{2}(370.11\ \text{mA})^2(1500\ \Omega) = \boxed{103\ \text{W}}$$

A power of 103 W is equal to 0.137 hp. Your friend is likely to tire. This is probably not an efficient way to generate power.

77 •• [SSM] Figure 28-60*a* shows an experiment designed to measure the acceleration due to gravity. A large plastic tube is encircled by a wire, which is arranged in single loops separated by a distance of 10 cm. A strong magnet is dropped through the top of the loop. As the magnet falls through each loop the voltage rises and then the voltage rapidly falls through zero to a large negative value and then returns to zero. The shape of the voltage signal is shown in Figure 28-62*b*. (*a*) Explain the basic physics behind the generation of this voltage pulse. (*b*) Explain why the tube cannot be made of a conductive material.
(*c*) Qualitatively explain the *shape* of the voltage signal in Figure 28-60*b*. (*d*) The times at which the voltage crosses zero as the magnet falls through each loop in succession are given in the table in the next column. Use these data to calculate a value for *g*.

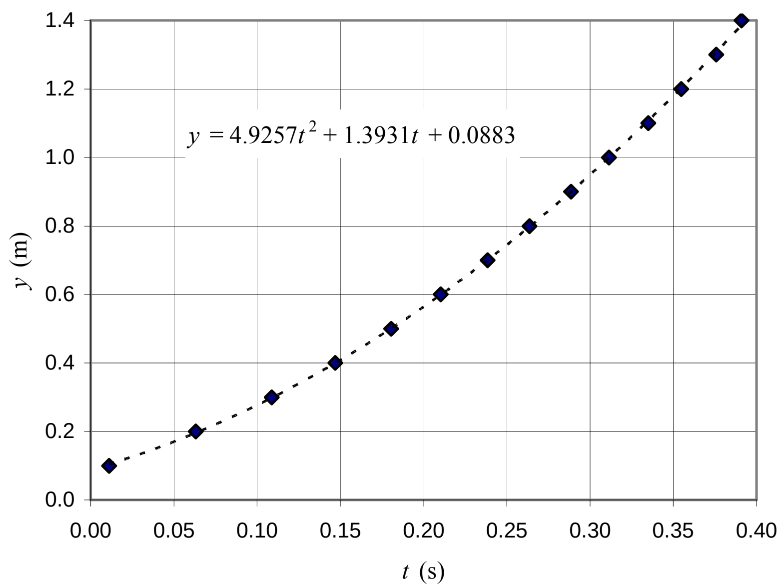
Picture the Problem

(*a*) As the magnet passes through a loop it induces an emf because of the changing flux through the loop. This allows the coil to ″sense″ when the magnet is passing through it.

(*b*) One cannot use a cylinder made of conductive material because eddy currents induced in it by a falling magnet would slow the magnet.

(*c*) As the magnet approaches the loop the flux increases, resulting in the negative voltage signal of increasing magnitude. When the magnet is passing a loop, the flux reaches a maximum value and then decreases, so the induced emf becomes zero and then positive. The instant at which the induced emf is zero is the instant at which the magnet is at the center of the loop.

(*d*) Each time represents a point when the distance has increased by 10 cm. The following graph of distance versus time was plotted using a spreadsheet program. The regression curve, obtained using Excel's ″Add Trendline″ feature, is shown as a dashed line.



The coefficient of the second-degree term is $\frac{1}{2}g$. Consequently,

$$g = 2\left(4.9257\,\text{m/s}^2\right) = \boxed{9.85\,\text{m/s}^2}$$

78 •• The rectangular coil shown in Figure 28-61 has 80 turns, is 25 cm wide, is 30 cm long, and is located in a magnetic field of 0.14 T directed out of the page, as shown. Only half of the coil is in the region of the magnetic field. The resistance of the coil is 24 Ω. Find the magnitude and the direction of the induced current if the coil is moved with a speed of 2.0 m/s (*a*) to the right, (*b*) up the page, (*c*) to the left, and (*d*) down the page.

Picture the Problem The current equals the induced emf divided by the resistance. We can calculate the emf induced in the circuit as the coil moves by calculating the rate of change of the flux through the coil. The flux is proportional to the area of the coil in the magnetic field. We can find the direction of the current from Lenz's law.

(*a*) and (*c*) Express the magnitude of the induced current:

$$I = \frac{|\mathcal{E}|}{R} \quad (1)$$

Using Faraday's law, express the magnitude of the induced emf:

$$|\mathcal{E}| = \frac{d\phi_m}{dt}$$

When the coil is moving to the right (or to the left), the flux does not change (until the coil leaves the region of magnetic field). Thus:

$$|\mathcal{E}| = \frac{d\phi_m}{dt} = 0 \Rightarrow I = \frac{|\mathcal{E}|}{R} = \boxed{0}$$

(*b*) Letting *x* represent the length of the side of the rectangular coil that is in the magnetic field, express the magnetic flux through the coil:

$$\phi_m = NBwx$$

Compute the rate of change of the flux when the coil is moving up or down:

$$\begin{aligned}\frac{d\phi_m}{dt} &= NBw\frac{dx}{dt}\\ &= (80)(0.14\,\text{T})(0.25\,\text{m})(2.0\,\text{m/s})\\ &= 5.60\,\text{V}\end{aligned}$$

Substitute in equation (1) to obtain:

$$I = \frac{5.60\,\text{V}}{24\,\Omega} = \boxed{0.23\,\text{A clockwise}}$$

(*d*) When the coil is moving downward, the outward flux decreases and the induced current will be in such a direction as to produce outward flux. The magnitude of the current is the same as in Part (*b*) and

$$I = \boxed{0.23\,\text{A counterclockwise}}\,.$$

79 •• [SSM] A long solenoid has *n* turns per unit length and carries a current that varies with time according to $I = I_0 \sin \omega t$. The solenoid has a circular cross section of radius *R*. Find the induced electric field, at points near the plane equidistant from the ends of the solenoid, as a function of both the time *t* and the perpendicular distance *r* from the axis of the solenoid for (*a*) $r < R$ and (*b*) $r > R$.

Picture the Problem We can apply Faraday's law to relate the induced electric field *E* to the rates at which the magnetic flux is changing at distances $r < R$ and $r > R$ from the axis of the solenoid.

(*a*) Apply Faraday's law to relate the induced electric field to the magnetic flux in the solenoid within a cylindrical region of radius $r < R$:

$$\int_C \vec{E} \cdot d\vec{\ell} = -\frac{d\phi_m}{dt}$$

or

$$E(2\pi r) = -\frac{d\phi_m}{dt} \qquad (1)$$

Express the field within the solenoid:

$$B = \mu_0 nI$$

Express the magnetic flux through an area for which $r < R$:

$$\phi_m = BA = \pi r^2 \mu_0 nI$$

Substitute in equation (1) to obtain:

$$E(2\pi r) = -\frac{d}{dt}\left[\pi r^2 \mu_0 nI\right] = -\pi r^2 \mu_0 n \frac{dI}{dt}$$

Because $I = I_0 \sin \omega t$:

$$E_{r<R} = -\tfrac{1}{2} r\mu_0 n \frac{d}{dt}\left[I_0 \sin \omega t\right] = \boxed{-\tfrac{1}{2} r\mu_0 nI_0 \omega \cos \omega t}$$

(*b*) Proceed as in (*a*) with $r > R$ to obtain:

$$E(2\pi r) = -\frac{d}{dt}\left[\pi R^2 \mu_0 nI\right] = -\pi R^2 \mu_0 n \frac{dI}{dt} = -\pi R^2 \mu_0 nI_0 \omega \cos \omega t$$

Solving for $E_{r>R}$ yields:

$$E_{r>R} = \boxed{-\frac{\mu_0 nR^2 I_0 \omega}{2r} \cos \omega t}$$

80 ••• A coaxial cable consists of two very thin-walled conducting cylinders of radii r_1 and r_2 (Figure 28-62). The currents in the inner and outer cylinders are equal in magnitude but opposite in direction. (*a*) Use Ampère's law to find the magnetic field as a function of the perpendicular distance r from the central axis of the cable for (1) $0 < r < r_1$ (2) $r_1 < r < r_2$ and (3) $r > r_2$. (*b*) Show that the magnetic energy density in the region between the cylinders is given by $\mu_m = \frac{1}{2}(\mu_0/4\pi)I^2/(\pi r^2)$. (*c*) Show that the total magnetic energy in a cable volume of length ℓ is given by $U_m = (\mu_0/4\pi)I^2\ell \ln(r_2/r_1)$. (*d*) Use the result in Part (*c*) and the relationship between magnetic energy, current and inductance to show that the self-inductance per unit length of this cable arrangement is given by $L/\ell = (\mu_0/2\pi)\ln(r_2/r_1)$.

Picture the Problem The system exhibits cylindrical symmetry, so one can use Ampère's law to determine B inside the inner cylinder, between the cylinders, and outside the outer cylinder. We can use $u_m = B^2/2\mu_0$ and the expression for B from Part (a) to express the magnetic energy density in the region between the cylinders. We can integrate this expression for u_m over the volume between the cylinders to find the total magnetic energy in a volume of length ℓ. Finally, we can use our result in Part (c) and $U_m = \frac{1}{2}LI^2$ to find the self-inductance of the cylinders per unit length.

(a) For $r < r_1$ and for $r > r_2$ the net enclosed current is zero; consequently, in these regions:

$$B(r < r_1) = \boxed{0}$$

and

$$B(r > r_2) = \boxed{0}$$

For $r_1 < r < r_2$:

$$2\pi rB = \mu_0 I_C \Rightarrow B(r_1 < r < r_2) = \boxed{\frac{\mu_0 I}{2\pi r}}$$

(b) Express the magnetic energy density in the region between the cylinders:

$$u_m = \frac{B^2}{2\mu_0}$$

Substitute for B and simplify to obtain:

$$u_m = \frac{\left(\frac{\mu_0 I}{2\pi r}\right)^2}{2\mu_0} = \boxed{\frac{\mu_0 I^2}{8\pi^2 r^2}}$$

(c) Express the magnetic energy dU_m in the cylindrical element of volume dV:

$$dU_m = u_m dV = \frac{\mu_0 I^2}{8\pi^2 r^2}(\ell 2\pi r dr)$$
$$= \frac{\mu_0 I^2 \ell}{4\pi} \cdot \frac{dr}{r}$$

Integrate this expression from $r = r_1$ to $r = r_2$ to obtain:

$$U_m = \frac{\mu_0 I^2 \ell}{4\pi}\int_{r_1}^{r_2} \frac{dr}{r} = \boxed{\frac{\mu_0}{4\pi} I^2 \ell \ln\left(\frac{r_2}{r_1}\right)}$$

(d) Express the energy in the magnetic field in terms of L and I:

$$U_m = \tfrac{1}{2}LI^2 \Rightarrow L = \frac{2U_m}{I^2}$$

From our result in (c):

$$\frac{U_m}{I^2} = \frac{\mu_0}{4\pi}\ell \ln\left(\frac{r_2}{r_1}\right)$$

Substitute to obtain:

$$L = 2\left[\frac{\mu_0}{4\pi}\ell \ln\left(\frac{r_2}{r_1}\right)\right] = \frac{\mu_0}{2\pi}\ell \ln\left(\frac{r_2}{r_1}\right)$$

Express the ratio L/ℓ:

$$\frac{L}{\ell} = \boxed{\frac{\mu_0}{2\pi}\ln\left(\frac{r_2}{r_1}\right)}$$

81 ••• A coaxial cable consists of two very thin-walled conducting cylinders of radii r_1 and r_2 (Figure 28-63). The currents in the inner and outer cylinders are equal in magnitude but opposite in direction. Compute the flux through a rectangular area of sides ℓ and $r_2 - r_1$ between the conductors shown in Figure 28-P95. Use the relationship between flux and current ($\phi_m = LI$) to show the self-inductance per unit length of the cable by is given by $L/\ell = (\mu_0/2\pi)\ln(r_2/r_1)$.

Picture the Problem We can use its definition to express the magnetic flux through a rectangular element of area dA and then integrate from $r = r_1$ to $r = r_2$ to express the total flux through the region. Substituting in $L = \phi_m/I$ will yield the same result found in Part (*d*) of Problem 80.

Use the definition of self-inductance to relate the magnetic flux through the region of interest to the current I:

$$L = \frac{\phi_m}{I} \qquad (1)$$

Consider a strip of unit length ℓ and width dr at a distance r from the axis. The flux through this area is given by:

$$d\phi_m = BdA = B\ell dr$$

Apply Ampere's law to express the magnetic field at a distance r from the axis:

$$2\pi rB = \mu_0 I \Rightarrow B = \frac{\mu_0 I}{2\pi r}$$

Substituting for B yields:

$$d\phi_m = \frac{\mu_0 I\ell}{2\pi}\frac{dr}{r}$$

Integrate from $r = r_1$ to $r = r_2$ to obtain:

$$\phi_m = \frac{\mu_0 I\ell}{2\pi}\int_{r_1}^{r_2}\frac{dr}{r} \Rightarrow \phi_m = \frac{\mu_0 I\ell}{2\pi}\ln\left(\frac{r_2}{r_1}\right)$$

Substituting for ϕ_m in equation (1) and dividing both sides by ℓ yields:

$$\frac{L}{\ell} = \boxed{\frac{\mu_0}{2\pi}\ln\left(\frac{r_2}{r_1}\right)}$$

82 ••• Figure 28-64 shows a rectangular loop of wire that is 0.300 m wide, is 1.50 m long, and lies in the vertical plane which is perpendicular to a region that has a uniform magnetic field. The magnitude of the uniform magnetic field is 0.400 T and the direction of the magnetic field is into the page. The portion of the loop not in the magnetic field is 0.100 m long. The resistance of the loop is 0.200 Ω and its mass is 50.0 g. The loop is released from rest at $t = 0$. (*a*) What is the magnitude and direction of the induced current when the loop has a downward speed v? (*b*) What is the force that acts on the loop as a result of this current? (*c*) What is the net force acting on the loop? (*d*) Write out Newton's second law for the loop. (*e*) Obtain an expression for the speed of the loop as a function of time. (*f*) Integrate the expression obtained in Part (*e*) to find the distance the loop falls as a function of time. (*g*) Using a **spreadsheet** program, make a graph of the position of the loop as a function of time (letting $t = 0$ at the start) for values of y between 0 and 1.40 m (i.e., when the loop leaves the magnetic field). (*h*) At what time does the loop completely leave the field region? Compare this to the time it would have taken if there were no field.

Picture the Problem We can use $I = \mathcal{E}/R$ and $\mathcal{E} = Bv\ell$ to find the current induced in the loop and Lenz's law to determine its direction. We can apply the equation for the force on a current-carrying wire to find the net magnetic force acting on the loop and then sum the forces to find the net force on the loop. Separating the variables in the differential equation and integrating will lead us to an expression for $v(t)$ and a second integration to an expression for $y(t)$. We can solve the latter equation for $y = 1.40$ m to find the time it takes the loop to exit the magnetic field and our expression for $v(t)$ to find its exit speed. Finally, we can use a constant-acceleration equation to find its exit speed in the absence of the magnetic field.

(*a*) Relate the magnitude of the induced current to the induced emf and the resistance of the loop:

$$I = \frac{\mathcal{E}}{R}$$

Relate the induced emf $\mathcal{E}$ to the motion of the loop:

$$\mathcal{E} = Bv\ell$$

where ℓ is the length of the horizontal portion of the loop.

Substitute for $\mathcal{E}$ to obtain:

$$I = \boxed{\frac{B\ell}{R}v}$$

As the loop falls, the flux into it (the loop) decreases. The direction of the induced current is such that its magnetic field opposes this decrease; i.e., clockwise.

(*b*) Express the velocity-dependent force that acts on the loop in terms of the current in the loop:

$$F_v = BI\ell$$

Substitute for I to obtain:

$$F_v = B\left(\frac{B\ell}{R}\right)v\ell = \boxed{\frac{B^2\ell^2}{R}v}$$

Apply $d\vec{F} = Id\vec{\ell}\times\vec{B}$ to the horizontal portion of the loop that is in the magnetic field to conclude that the net magnetic force is upward. Note that the magnetic force on the left side of the loop is to the left and the magnetic force on the right side of the loop is to the right.

(*c*) The net force acting on the loop is the difference between the downward gravitational force and the upward magnetic force:

$$F_{\text{net}} = mg - F_v = \boxed{mg - \frac{B^2\ell^2}{R}v}$$

(*d*) Apply Newton's second law of motion to the loop to obtain its equation of motion:

$$mg - \frac{B^2\ell^2}{R}v = m\frac{dv}{dt} \Rightarrow \frac{dv}{dt} = g - \frac{B^2\ell^2}{mR}v$$

Factor g to obtain an alternate form of the equation of motion:

$$\frac{dv}{dt} = g\left(1 - \frac{B^2\ell^2}{mgR}v\right) = \boxed{g\left(1 - \frac{v}{v_{\text{t}}}\right)}$$

where $v_{\text{t}} = \dfrac{mgR}{B^2\ell^2}$

(*e*) Separating the variables yields:

$$\frac{dv}{g - \dfrac{B^2\ell^2}{mR}v} = dt \text{ or } \frac{dv}{a - bv} = dt$$

where $a = g$ and $b = \dfrac{B^2\ell^2}{mR}$

Integrate v from 0 to v and t from 0 to t:

$$\int_0^v \frac{dv}{a - bv} = \int_0^t dt \Rightarrow -\frac{1}{b}\ln\left(\frac{a - bv}{a}\right) = t$$

Transforming from logarithmic to exponential form and solving for v yields:

$$v(t) = \frac{a}{b}\left(1 - e^{-bt}\right)$$

Noting that $v_t = \dfrac{a}{b}$, we have:

$$v(t) = \boxed{v_t\left(1 - e^{-t/\tau}\right)}$$

where $v_t = \dfrac{mgR}{B^2\ell^2}$ and $\tau = \dfrac{v_t}{a} = \dfrac{v_t}{g}$.

(*f*) Write v as dy/dt and separate variables to obtain:

$$dy = v_t\left(1 - e^{-t/\tau}\right)dt$$

Integrate y from 0 to y and t from 0 to t:

$$\int_0^y dy = v_t \int_0^t \left(1 - e^{-t/\tau}\right)dt$$

and

$$y(t) = \boxed{v_t\left[t - \tau\left(1 - e^{-t/\tau}\right)\right]}$$

(*g*) A spreadsheet program to generate the data for graphs of position y as a function of time t is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	0.0500	m
B2	0.200	R
B3	0.400	B
B4	0.300	L
B5	$B$1*$B$7*$B$2/($B$3^2*$B$4^2)	v_t
B6	$B$5/$B$7	τ
B7	9.81	g

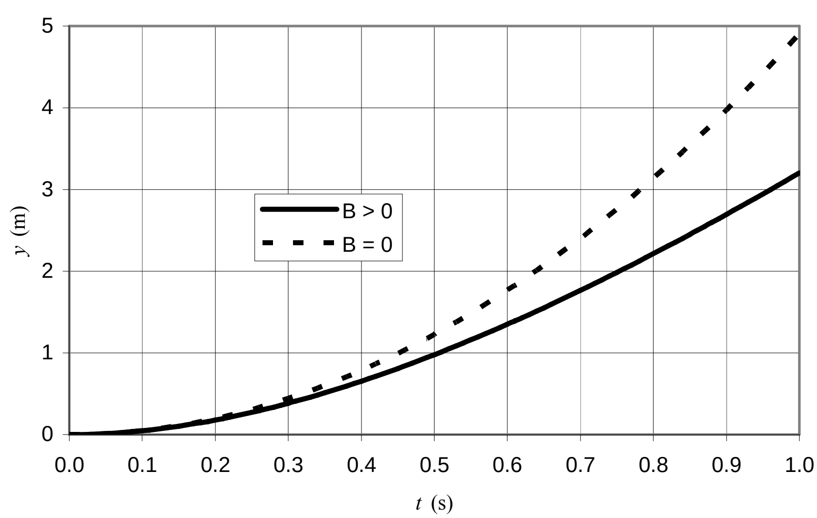
71	0.61	1.390	1.825
72	0.62	1.430	1.885
73	0.63	1.471	1.947
74	0.64	1.511	2.009

Examination of either the table or the following graph shows that, when the loop falls in the magnetic field, $y = 1.4$ m when $t \approx \boxed{0.61\text{s.}}$ In the absence of the magnetic field, $y = 1.4$ m when $t \approx \boxed{0.53\text{s.}}$

The following graph shows y as a function of t for $B \neq 0$ (solid curve) and $B = 0$ (dashed curve).



In the absence of the magnetic field, the loop fall a distance of 1.40 m in about 0.08 s less time than it takes to fall the same distance in the presence of the magnetic field.

83 ••• A coil of N turns and area A suspended from the ceiling by a wire that provides a linear restoring torque with torsion constant κ. The two ends of the coil are connected to each other, the coil has resistance R, and the moment of inertia of the coil is I. The plane of the coil is vertical, and parallel to a uniform horizontal magnetic field $\vec{B}$ when the wire is not twisted (i.e., $\theta = 0$). The coil is rotated about a vertical axis through its center by a small angle θ_0 and released. The coil then undergoes damped harmonic oscillation. Show that its angle with its equilibrium position will vary with time according to $\theta(t) = \theta_0 e^{-t/2\tau}\cos\omega' t$, where $\tau = RI/(NBA)^2$, $\omega_0 = \sqrt{\kappa/I}$ and $\omega' = \omega_0\sqrt{1-(2\omega_0\tau)^{-2}}$.

Picture the Problem Picture the Problem If the coil is rotated through an angle θ, the wire exerts a restoring torque equal to $-\kappa\theta$ acts on it returning it to its equilibrium position. However, when it rotates with angular speed $d\theta/dt$, there will be an emf induced in the coil. The direction of the current resulting from this induced emf will be such that its magnetic field will oppose the change in flux resulting from the rotation of the coil. The net effect is that the magnetic field exerts a torque on the coil in a direction opposite to the direction of the angular velocity of the coil. We can show that θ will vary with time according to $\theta(t) = \theta_0 e^{-t/2\tau}\cos\omega' t$,where $\tau = RI/(NBA)^2$, $\omega_0 = \sqrt{\kappa/I}$ and $\omega' = \omega_0\sqrt{1-(2\omega_0\tau)^{-2}}$ by demonstrating that $\theta(t) = \theta_0 e^{-t/2\tau}\cos\omega' t$ satisfies the differential equation obtained in our solution for Part (a).

Apply $\sum\tau = I\alpha$ to the rotating coil to obtain:

$$\tau_{\text{restoring}} - \tau_{\text{retarding}} = I\frac{d^2\theta}{dt^2}$$

The magnitude of the retarding (damping) torque is given by:

$$\tau_{\text{retarding}} = NiBA\cos\theta$$

where i is the current induced in the coil whose cross-sectional area is A.

Substitute for $\tau_{\text{restoring}}$ and $\tau_{\text{retarding}}$ to obtain:

$$-\kappa\theta - NiBA\cos\theta = I\frac{d^2\theta}{dt^2} \qquad (1)$$

Apply Faraday's law to express the emf induced in the coil:

$$\mathcal{E} = -\frac{d}{dt}(NBA\sin\theta) = -(NBA\cos\theta)\frac{d\theta}{dt}$$

From Ohm's law, the magnitude of the induced current i in the coil is:

$$i=\frac{\varepsilon}{R}=\frac{NBA\cos\theta}{R}\frac{d\theta}{dt}$$

Substitute for the induced current i in equation (1) to obtain:

$$-\kappa\theta-\frac{(NBA)^2\cos^2\theta}{R}\frac{d\theta}{dt}=I\frac{d^2\theta}{dt^2}$$

For small displacements from equilibrium, $\cos\theta\approx 1$ and:

$$-\kappa\theta-\frac{(NBA)^2}{R}\frac{d\theta}{dt}\approx I\frac{d^2\theta}{dt^2}$$

Rearrange to express the differential equation in standard form, then substitute using $\omega_0=\sqrt{\kappa/I}$ and $\tau=RI/(NBA)^2$:

$$\frac{d^2\theta}{dt^2}+\frac{(NBA)^2}{RI}\frac{d\theta}{dt}+\frac{\kappa}{I}\theta\approx 0$$

or

$$\frac{d^2\theta}{dt^2}+\frac{1}{\tau}\frac{d\theta}{dt}+\omega_0^2\theta=0 \qquad (2)$$

Assume that the solution to equation (2) is given by $\theta(t)=\theta_0e^{-t/2\tau}\cos\omega't$ and evaluate its first and second derivatives with respect to time:

$$\begin{aligned}\frac{d\theta}{dt}&=\theta_0\frac{d}{dt}\left[e^{-t/2\tau}\cos\omega't\right]=\theta_0\left[e^{-t/2\tau}\frac{d}{dt}(\cos\omega't)+\cos\omega't\frac{d}{dt}\left(e^{-t/2\tau}\right)\right]\\&=\theta_0\left(-\omega'e^{-t/2\tau}\sin\omega't-\frac{1}{2\tau}e^{-t/2\tau}\theta_0\cos\omega't\right)\\&=-\theta_0e^{-t/2\tau}\left(\omega'\sin\omega't+\frac{1}{2\tau}\cos\omega't\right)\end{aligned}$$

and

$$\begin{aligned}\frac{d^2\theta}{dt^2}&=\frac{d}{dt}\left[-\theta_0\omega'e^{-t/2\tau}\sin\omega't-\theta_0\frac{1}{2\tau}e^{-t/2\tau}\cos\omega't\right]\\&=-\theta_0e^{-t/2\tau}\frac{d}{dt}\left(\omega'\sin\omega't+\frac{1}{2\tau}\cos\omega't\right)\\&\qquad-\theta_0\left(\omega'\sin\omega't+\frac{1}{2\tau}\cos\omega't\right)\frac{d}{dt}e^{-t/2\tau}\\&=-\theta_0e^{-t/2\tau}\left(\omega'^2\cos\omega't-\frac{\omega'}{2\tau}\sin\omega't\right)\\&\qquad+\theta_0\frac{1}{2\tau}\left(\omega'\sin\omega't+\frac{1}{2\tau}\cos\omega't\right)e^{-t/2\tau}\\&=-\theta_0e^{-t/2\tau}\left(\omega'^2\cos\omega't-\frac{\omega'}{\tau}\sin\omega't-\frac{1}{4\tau^2}\cos\omega't\right)\end{aligned}$$

Substitute these derivatives in equation (2) to obtain:

$$-\theta_0 e^{-t/2\tau}\left(\omega'^2\cos\omega' t-\frac{\omega'}{\tau}\sin\omega' t-\frac{1}{4\tau^2}\cos\omega' t\right)$$
$$-\frac{1}{\tau}\theta_0 e^{-t/2\tau}\left(\omega'\sin\omega' t+\frac{1}{2\tau}\cos\omega' t\right)+\omega_0^2\theta_0 e^{-t/2\tau}\cos\omega' t=0$$

Because θ_0 and $e^{-t/\tau}$ are never zero, we can divide them out of the equation and simplify to obtain:

$$-\omega'^2\cos\omega' t-\frac{1}{4\tau^2}\cos\omega' t+\omega_0^2\cos\omega' t=0$$

or

$$\left(-\omega'^2-\frac{1}{4\tau^2}+\omega_0^2\right)\cos\omega' t=0$$

This equation is satisfied provided: $$-\omega'^2-\frac{1}{4\tau^2}+\omega_0^2=0$$

Solving for ω' yields: $$\omega'=\omega_0\sqrt{1-(2\omega_0\tau)^{-2}}$$

Thus we've shown that the angular position of the oscillating coil, relative to its equilibrium position, varies with time according to $\theta(t)=\theta_0 e^{-t/2\tau}\cos\omega' t$, where $\tau=RI/(NBA)^2$, $\omega_0=\sqrt{\kappa/I}$ and $\omega'=\omega_0\sqrt{1-(2\omega_0\tau)^{-2}}$.

Chapter 29
Alternating-Current Circuits

Conceptual Problems

1 • A coil in an ac generator rotates at 60 Hz. How much time elapses between successive peak emf values of the coil?

Determine the Concept Successive peaks are one-half period apart. Hence the elapsed time between the peaks is $\frac{1}{2}T = \frac{1}{2f} = \frac{1}{2(60\ \text{s}^{-1})} = \boxed{8.33\ \text{ms}}$.

2 • If the rms voltage in an ac circuit is doubled, the peak voltage is (*a*) doubled, (*b*) halved, (*c*) increased by a factor of $\sqrt{2}$, (*d*) not changed.

Picture the Problem We can use the relationship between V and V_{peak} to decide the effect of doubling the rms voltage on the peak voltage.

Express the initial rms voltage in terms of the peak voltage:

$$V_{\text{rms}} = \frac{V_{\text{peak}}}{\sqrt{2}}$$

Express the doubled rms voltage in terms of the new peak voltage V'_{peak}:

$$2V_{\text{rms}} = \frac{V'_{\text{peak}}}{\sqrt{2}}$$

Divide the second of these equations by the first and simplify to obtain:

$$\frac{2V_{\text{rms}}}{V_{\text{rms}}} = \frac{\frac{V'_{\text{peak}}}{\sqrt{2}}}{\frac{V_{\text{peak}}}{\sqrt{2}}} \Rightarrow 2 = \frac{V'_{\text{peak}}}{V_{\text{peak}}}$$

Solving for V'_{peak} yields:

$$V'_{\text{peak}} = 2V_{\text{peak}} \Rightarrow \boxed{(a)} \text{ is correct.}$$

3 • **[SSM]** If the frequency in the circuit shown in Figure 29-27 is doubled, the inductance of the inductor will (*a*) double, (*b*) not change, (*c*) halve, (*d*) quadruple.

Determine the Concept The inductance of an inductor is determined by the details of its construction and is independent of the frequency of the circuit. The inductive reactance, on the other hand, is frequency dependent. $\boxed{(b)}$ is correct.

4 • If the frequency in the circuit shown in Figure 29-27 is doubled, the inductive reactance of the inductor will (*a*) double, (*b*) not change, (*c*) halve, (*d*) quadruple.

Determine the Concept The inductive reactance of an inductor varies with the frequency according to $X_L = \omega L$. Hence, doubling ω will double X_L. $\boxed{(a)}$ is correct.

5 • If the frequency in the circuit in Figure 29-28 is doubled, the capacitive reactance of the circuit will (*a*) double, (*b*) not change, (*c*) halve, (*d*) quadruple.

Determine the Concept The capacitive reactance of an capacitor varies with the frequency according to $X_C = 1/\omega C$. Hence, doubling ω will halve X_C. $\boxed{(c)}$ is correct.

6 • (*a*) In a circuit consisting solely of a ac generator and an ideal inductor, are there any time intervals when the inductor receives energy from the generator? If so, when? Explain your answer. (*b*) Are there any time intervals when the inductor supplies energy back to the generator? If so when? Explain your answer.

Determine the Concept Yes to both questions. (*a*) While the magnitude of the current in the inductor is increasing, the inductor absorbs power from the generator. (*b*) When the magnitude of the current in the inductor decreases, the inductor supplies power to the generator.

7 • **[SSM]** (*a*) In a circuit consisting of a generator and a capacitor, are there any time intervals when the capacitor receives energy from the generator? If so, when? Explain your answer. (*b*) Are there any time intervals when the capacitor supplies power to the generator? If so, when? Explain your answer.

Determine the Concept Yes to both questions. (*a*) While the magnitude of the charge is accumulating on either plate of the capacitor, the capacitor absorbs power from the generator. (*b*) When the magnitude of the charge is on either plate of the capacitor is decreasing, it supplies power to the generator.

8 • (*a*) Show that the SI unit of inductance multiplied by the SI unit of capacitance is equivalent to seconds squared. (*b*) Show that the SI unit of inductance divided by the SI unit of resistance is equivalent to seconds.

Determine the Concept

(*a*) Substitute the SI units of inductance and capacitance and simplify to obtain:

$$\frac{\text{V}\cdot\text{s}}{\text{A}}\cdot\frac{\text{C}}{\text{V}} = \frac{\text{s}}{\frac{\text{C}}{\text{s}}}\cdot\text{C} = \boxed{\text{s}^2}$$

(*b*) Substitute the SI units of inductance divided by resistance and simplify to obtain:

$$\frac{\frac{\text{V}\cdot\text{s}}{\text{A}}}{\Omega}=\frac{\frac{\text{V}\cdot\text{s}}{\text{A}}}{\frac{\text{V}}{\text{A}}}=\boxed{\text{s}}$$

9 • **[SSM]** Suppose you increase the rotation rate of the coil in the generator shown in the simple ac circuit in Figure 29-29. Then the rms current (*a*) increases, (*b*) does not change, (*c*) may increase or decrease depending on the magnitude of the original frequency, (*d*) may increase or decrease depending on the magnitude of the resistance, (*e*) decreases.

Determine the Concept Because the rms current through the resistor is given by $I_{\text{rms}}=\frac{\mathcal{E}_{\text{rms}}}{R}=\frac{\mathcal{E}_{\text{peak}}}{\sqrt{2}}=\frac{NBA}{\sqrt{2}}\omega$, I_{rms} is directly proportional to ω. $\boxed{(a)}$ is correct.

10 • If the inductance value is tripled in a circuit consisting solely of a variable inductor and a variable capacitor, how would you have to change the capacitance so that the natural frequency of the circuit is unchanged? (*a*) triple the capacitance, (*b*) decrease the capacitance to one-third of its original value, (*c*) You should not change the capacitance.(*d*) You cannot determine how to change the capacitance from the data given.

Determine the Concept The natural frequency of an *LC* circuit is given by $f_0=1/2\pi\sqrt{LC}$.

Express the natural frequencies of the circuit before and after the inductance is tripled:

$$f_0=\frac{1}{2\pi\sqrt{LC}}\text{ and }f_0^{'}=\frac{1}{2\pi\sqrt{L'C'}}$$

Divide the second of the these equations by the first and simplify to obtain:

$$\frac{f_0^{'}}{f_0}=\frac{\frac{1}{2\pi\sqrt{L'C'}}}{\frac{1}{2\pi\sqrt{LC}}}=\sqrt{\frac{LC}{L'C'}}$$

Because the natural frequency is unchanged:

$$1=\sqrt{\frac{LC}{L'C'}}\Rightarrow\frac{LC}{L'C'}=1\Rightarrow C'=\frac{L}{L'}C$$

When the inductance is tripled:

$$C'=\frac{L}{3L}C=\frac{1}{3}C\Rightarrow\boxed{(b)}\text{ is correct.}$$

11 • **[SSM]** Consider a circuit consisting solely of an ideal inductor and an ideal capacitor. How does the maximum energy stored in the capacitor compare to the maximum value stored in the inductor? (*a*) They are the same and each equal to the total energy stored in the circuit. (*b*) They are the same and each

equal to half of the total energy stored in the circuit. (*c*) The maximum energy stored in the capacitor is larger than the maximum energy stored in the inductor. (*d*) The maximum energy stored in the inductor is larger than the maximum energy stored in the capacitor. (*e*) You cannot compare the maximum energies based on the data given because the ratio of the maximum energies depends on the actual capacitance and inductance values.

Determine the Concept The maximum energy stored in the electric field of the capacitor is given by $U_e = \frac{1}{2}\frac{Q^2}{C}$ and the maximum energy stored in the magnetic field of the inductor is given by $U_m = \frac{1}{2}LI^2$. Because energy is conserved in an LC circuit and oscillates between the inductor and the capacitor, $U_e = U_m = U_{total}$. $\boxed{(a)}$ is correct.

12 • True or false:

(*a*) A driven series *RLC* circuit that has a high *Q* factor has a narrow resonance curve.
(*b*) A circuit consists solely of a resistor, an inductor and a capacitor, all connected in series. If the resistance of the resistor is doubled, the natural frequency of the circuit remains the same.
(*c*) At resonance, the impedance of a driven series *RLC* combination equals the resistance *R*.
(*d*) At resonance, the current in a driven series *RLC* circuit is in phase with the voltage applied to the combination.

(*a*) True. The *Q* factor and the width of the resonance curve at half power are related according to $Q = \omega_0/\Delta\omega$; i.e., they are inversely proportional to each other.

(*b*) True. The natural frequency of the circuit depends only on the inductance *L* of the inductor and the capacitance *C* of the capacitor and is given by $\omega = 1/\sqrt{LC}$.

(*c*) True. The impedance of an *RLC* circuit is given by $Z = \sqrt{R^2 + (X_L - X_C)^2}$. At resonance $X_L = X_C$ and so $Z = R$.

(*d*) True. The phase angle δ is related to X_L and X_C according to $\delta = \tan^{-1}\left(\frac{X_L - X_C}{R}\right)$. At resonance $X_L = X_C$ and so $\delta = 0$.

13 • True or false (all questions related to a driven series *RLC* circuit):

(*a*) Near resonance, the power factor of a driven series *RLC* circuit is close to zero.
(*b*) The power factor of a driven series *RLC* circuit does not depend on the value of the resistance.
(*c*) The resonance frequency of a driven series *RLC* circuit does not depend on the value of the resistance.
(*d*) At resonance, the peak current of a driven series *RLC* circuit does not depend on the capacitance or the inductance.
(*e*) For frequencies below the resonant frequency, the capacitive reactance of a driven series *RLC* circuit is larger than the inductive reactance.
(*f*) For frequencies below the resonant frequency of a driven series *RLC* circuit, the phase of the current leads (is ahead of) the phase of the applied voltage.

(*a*) False. Near resonance, the power factor, given by $\cos\delta = \dfrac{R}{\sqrt{(X_L - X_C)^2 + R^2}}$, is close to 1.

(*b*) False. The power factor is given by $\cos\delta = \dfrac{R}{\sqrt{(X_L - X_C)^2 + R^2}}$.

(*c*) True. The resonance frequency for a driven series *RLC* circuit depends only on *L* and *C* and is given by $\omega_{\text{res}} = 1/\sqrt{LC}$

(*d*) True. At resonance $X_L - X_C = 0$ and so $Z = R$ and the peak current is given by $I_{\text{peak}} = V_{\text{app, peak}}/R$.

(*e*) True. Because the capacitive reactance varies inversely with the driving frequency and the inductive reactance varies directly with the driving frequency, at frequencies well below the resonance frequency the capacitive reactance is larger than the inductive reactance.

(*f*) True. For frequencies below the resonant frequency, the circuit is more capacitive than inductive and the phase constant ϕ is negative. This means that the current leads the applied voltage.

14 • You may have noticed that sometimes two radio stations can be heard when your receiver is tuned to a specific frequency. This situation often occurs when you are driving and are between two cities. Explain how this situation can occur.

Determine the Concept Because the power curves received by your radio from two stations have width, you could have two frequencies overlapping as a result of receiving signals from both stations.

15 • True or false (all questions related to a driven series *RLC* circuit):

(*a*) At frequencies much higher than or much lower than the resonant frequency of a driven series *RLC* circuit, the power factor is close to zero.
(*b*) The larger the resonance width of a driven series *RLC* circuit is, the larger the *Q* factor for the circuit is.
(*c*) The larger the resistance of a driven series *RLC* circuit is, the larger the resonance width for the circuit is.

(*a*) True. Because the power factor is given by $\cos\delta = R\Big/\sqrt{\left(\omega L - \frac{1}{\omega C}\right)^2 + R^2}$, for values of ω that are much higher or much lower than the resonant frequency, the term in parentheses becomes very large and $\cos\delta$ approaches zero.

(*b*) False. When the resonance curve is reasonably narrow, the *Q* factor can be approximated by $Q = \omega_0/\Delta\omega$. Hence a large value for *Q* corresponds to a narrow resonance curve.

(*c*) True. See Figure 29-21.

16 • An ideal transformer has N_1 turns on its primary and N_2 turns on its secondary. The average power delivered to a load resistance *R* connected across the secondary is P_2 when the primary rms voltage is V_1. The rms current in the primary windings can then be expressed as (*a*) P_2/V_1, (*b*) $(N_1/N_2)(P_2/V_1)$, (*c*) $(N_2/N_1)(P_2/V_1)$, (*d*) $(N_2/N_1)2(P_2/V_1)$.

Picture the Problem Let the subscript 1 denote the primary and the subscript 2 the secondary. Assuming no loss of power in the transformer, we can equate the power in the primary circuit to the power in the secondary circuit and solve for the rms current in the primary windings.

Assuming no loss of power in the transformer: $P_1 = P_2$

Substitute for P_1 and P_2 to obtain: $I_{1,\,\text{rms}}V_{1,\,\text{rms}} = I_{2,\,\text{rms}}V_{2,\,\text{rms}}$

Solving for $I_{1,\mathrm{rms}}$ and simplifying yields:

$$I_{1,\,\mathrm{rms}} = \frac{I_{2,\,\mathrm{rms}} V_{2,\,\mathrm{rms}}}{V_{1,\,\mathrm{rms}}} = \frac{P_2}{V_{1,\,\mathrm{rms}}}$$

$\boxed{(a)}$ is correct.

17 • **[SSM]** True or false:

(*a*) A transformer is used to change frequency.
(*b*) A transformer is used to change voltage.
(*c*) If a transformer steps up the current, it must step down the voltage.
(*d*) A step-up transformer, steps down the current.
(*e*) The standard household wall-outlet voltage in Europe is 220 V, about twice that used in the United States. If a European traveler wants her hair dryer to work properly in the United States, she should use a transformer that has more windings in its secondary coil than in its primary coil.
(*f*) The standard household wall-outlet voltage in Europe is 220 V, about twice that used in the United States. If an American traveler wants his electric razor to work properly in Europe, he should use a transformer that steps up the current.

(*a*) False. A transformer is a device used to raise or lower the voltage in a circuit.

(*b*) True. A transformer is a device used to raise or lower the voltage in a circuit.

(*c*) True. If energy is to be conserved, the product of the current and voltage must be constant.

(*d*) True. Because the product of current and voltage in the primary and secondary circuits is the same, increasing the current in the secondary results in a lowering (or stepping down) of the voltage.

(*e*) True. Because electrical energy is provided at a higher voltage in Europe, the visitor would want to step-up the voltage in order to make her hair dryer work properly.

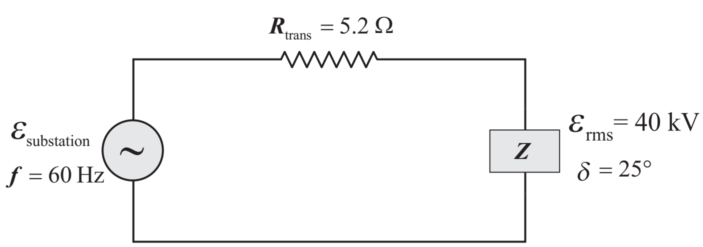
(*f*) True. Because electrical energy is provided at a higher voltage in Europe, the visitor would want to step-up the current (and decrease the voltage) in order to make his razor work properly.

Estimation and Approximation

18 •• The impedances of motors, transformers, and electromagnets include both resistance and inductive reactance. Suppose that phase of the current to a

large industrial plant lags the phase of the applied voltage by 25° when the plant is under full operation and using 2.3 MW of power. The power is supplied to the plant from a substation 4.5 km from the plant; the 60 Hz rms line voltage at the plant is 40 kV. The resistance of the transmission line from the substation to the plant is 5.2 Ω. The cost per kilowatt-hour to the company that owns the plant is $0.14, and the plant pays only for the actual energy used. (*a*) Estimate the resistance and inductive reactance of the plant's total load. (*b*) Estimate the rms current in the power lines and the rms voltage at the substation. (*c*) How much power is lost in transmission? (*d*) Suppose that the phase that the current lags the phase of the applied voltage is reduced to 18º by adding a bank of capacitors in series with the load. How much money would be saved by the electric utility during one month of operation, assuming the plant operates at full capacity for 16 h each day? (*e*) What must be the capacitance of this bank of capacitors to achieve this change in phase angle?

Picture the Problem We can find the resistance and inductive reactance of the plant's total load from the impedance of the load and the phase constant. The current in the power lines can be found from the total impedance of the load the potential difference across it and the rms voltage at the substation by applying Kirchhoff's loop rule to the substation-transmission wires-load circuit. The power lost in transmission can be found from $P_{\text{trans}} = I_{\text{rms}}^2 R_{\text{trans}}$. We can find the cost savings by finding the difference in the power lost in transmission when the phase angle is reduced to 18°. Finally, we can find the capacitance that is required to reduce the phase angle to 18° by first finding the capacitive reactance using the definition of tanδ and then applying the definition of capacitive reactance to find *C*.



(*a*) Relate the resistance and inductive reactance of the plant's total load to *Z* and δ:

$$R = Z\cos\delta$$
and
$$X_L = Z\sin\delta$$

Express *Z* in terms of the rms current I_{rms} in the power lines and the rms voltage $\mathcal{E}_{\text{rms}}$ at the plant:

$$Z = \frac{\mathcal{E}_{\text{rms}}}{I_{\text{rms}}}$$

Express the power delivered to the plant in terms of $\mathcal{E}_{rms}$, I_{rms}, and δ and solve for I_{rms}:

$$P_{av} = \mathcal{E}_{rms} I_{rms} \cos\delta$$

and

$$I_{rms} = \frac{P_{av}}{\mathcal{E}_{rms}\cos\delta} \qquad (1)$$

Substitute to obtain:

$$Z = \frac{\varepsilon_{rms}^2 \cos\delta}{P_{av}}$$

Substitute numerical values and evaluate Z:

$$Z = \frac{(40\,\text{kV})^2 \cos 25°}{2.3\,\text{MW}} = 630\,\Omega$$

Substitute numerical values and evaluate R and X_L:

$$R = (630\,\Omega)\cos 25° = 571\,\Omega = \boxed{0.57\,\text{k}\Omega}$$

and

$$X_L = (630\,\Omega)\sin 25° = 266\,\Omega = \boxed{0.27\,\text{k}\Omega}$$

(*b*) Use equation (1) to find the current in the power lines:

$$I_{rms} = \frac{2.3\,\text{MW}}{(40\,\text{kV})\cos 25°} = 63.4\,\text{A} = \boxed{63\,\text{A}}$$

Apply Kirchhoff's loop rule to the circuit:

$$\mathcal{E}_{sub} - I_{rms}R_{trans} - I_{rms}Z_{tot} = 0$$

Solve for $\mathcal{E}_{sub}$:

$$\mathcal{E}_{sub} = I_{rms}(R_{trans} + Z_{tot})$$

Substitute numerical values and evaluate $\mathcal{E}_{sub}$:

$$\mathcal{E}_{sub} = (63.4\,\text{A})(5.2\,\Omega + 630\,\Omega) = \boxed{40.3\,\text{kV}}$$

(*c*) The power lost in transmission is:

$$P_{trans} = I_{rms}^2 R_{trans} = (63.4\,\text{A})^2(5.2\,\Omega) = 20.9\,\text{kW} = \boxed{21\,\text{kW}}$$

(*d*) Express the cost savings ΔC in terms of the difference in energy consumption $(P_{25°} - P_{18°})\Delta t$ and the per-unit cost u of the energy:

$$\Delta C = (P_{25°} - P_{18°})\Delta t u$$

Express the power lost in transmission when $\delta = 18°$:

$$P_{18°} = I_{18°}^2 R_{\text{trans}}$$

Find the current in the transmission lines when $\delta = 18°$:

$$I_{18°} = \frac{2.3\,\text{MW}}{(40\,\text{kV})\cos 18°} = 60.5\,\text{A}$$

Evaluate $P_{18°}$:

$$P_{18°} = (60.5\,\text{A})^2(5.2\,\Omega) = 19.0\,\text{kW}$$

Substitute numerical values and evaluate ΔC:

$$\Delta C = (20.9\,\text{kW} - 19.0\,\text{kW})\left(16\frac{\text{h}}{\text{d}}\right)\left(30\frac{\text{d}}{\text{month}}\right)\left(\frac{\$0.14}{\text{kW}\cdot\text{h}}\right) = \boxed{\$128}$$

(*e*) The required capacitance is given by:

$$C = \frac{1}{2\pi f X_C}$$

Relate the new phase angle δ to the inductive reactance X_L, the reactance due to the added capacitance X_C, and the resistance of the load R:

$$\tan\delta = \frac{X_L - X_C}{R} \Rightarrow X_C = X_L - R\tan\delta$$

Substituting for X_C yields:

$$C = \frac{1}{2\pi f\,(X_L - R\tan\delta)}$$

Substitute numerical values and evaluate C:

$$C = \frac{1}{2\pi(60\,\text{s}^{-1})(266\,\Omega - (571\,\Omega)\tan 18°)} = \boxed{33\,\mu\text{F}}$$

Alternating Current in Resistors, Inductors, and Capacitors

19 • [SSM] A 100-W light bulb is screwed into a standard 120-V-rms socket. Find (*a*) the rms current, (*b*) the peak current, and (*c*) the peak power.

Picture the Problem We can use $P_{\text{av}} = \mathcal{E}_{\text{rms}} I_{\text{rms}}$ to find I_{rms}, $I_{\text{peak}} = \sqrt{2} I_{\text{rms}}$ to find I_{peak}, and $P_{\text{peak}} = I_{\text{peak}}\mathcal{E}_{\text{peak}}$ to find P_{peak}.

(*a*) Relate the average power delivered by the source to the rms voltage across the bulb and the rms current through it:

$$P_{\text{av}} = \mathcal{E}_{\text{rms}} I_{\text{rms}} \Rightarrow I_{\text{rms}} = \frac{P_{\text{av}}}{\mathcal{E}_{\text{rms}}}$$

Substitute numerical values and evaluate I_{rms}:

$$I_{\text{rms}} = \frac{100\,\text{W}}{120\,\text{V}} = 0.8333\text{ A} = \boxed{0.833\,\text{A}}$$

(*b*) Express I_{peak} in terms of I_{rms}:

$$I_{\text{peak}} = \sqrt{2}I_{\text{rms}}$$

Substitute for I_{rms} and evaluate I_{peak}:

$$I_{\text{peak}} = \sqrt{2}(0.8333\,\text{A}) = 1.1785\text{ A} = \boxed{1.18\,\text{A}}$$

(*c*) Express the maximum power in terms of the maximum voltage and maximum current:

$$P_{\text{peak}} = I_{\text{peak}}\mathcal{E}_{\text{peak}}$$

Substitute numerical values and evaluate P_{peak}:

$$P_{\text{peak}} = (1.1785\,\text{A})\sqrt{2}(120\,\text{V}) = \boxed{200\,\text{W}}$$

20 • A circuit breaker is rated for a current of 15 A rms at a voltage of 120 V rms. (*a*) What is the largest value of the peak current that the breaker can carry? (*b*) What is the maximum average power that can be supplied by this circuit?

Picture the Problem We can $I_{\text{peak}} = \sqrt{2}I_{\text{rms}}$ to find the largest peak current the breaker can carry and $P_{\text{av}} = I_{\text{rms}}V_{\text{rms}}$ to find the average power supplied by this circuit.

(*a*) Express I_{peak} in terms of I_{rms}:

$$I_{\text{peak}} = \sqrt{2}I_{\text{rms}} = \sqrt{2}(15\,\text{A}) = \boxed{21\,\text{A}}$$

(*b*) Relate the average power to the rms current and voltage:

$$P_{\text{av}} = I_{\text{rms}}V_{\text{rms}} = (15\,\text{A})(120\,\text{V}) = \boxed{1.8\,\text{kW}}$$

21 • **[SSM]** What is the reactance of a 1.00-μH inductor at (*a*) 60 Hz, (*b*) 600 Hz, and (*c*) 6.00 kHz?

Picture the Problem We can use $X_L = \omega L$ to find the reactance of the inductor at any frequency.

Express the inductive reactance as a function of *f*:

$$X_L = \omega L = 2\pi f L$$

(*a*) At *f* = 60 Hz:

$$X_L = 2\pi\left(60\,\text{s}^{-1}\right)(1.00\,\text{mH}) = \boxed{0.38\,\Omega}$$

(*b*) At $f = 600$ Hz: $X_L = 2\pi\left(600\,\text{s}^{-1}\right)\left(1.00\,\text{mH}\right) = \boxed{3.77\,\Omega}$

(*c*) At $f = 6.00$ kHz: $X_L = 2\pi\left(6.00\,\text{kHz}\right)\left(1.00\,\text{mH}\right) = \boxed{37.7\,\Omega}$

22 • An inductor has a reactance of 100 Ω at 80 Hz. (*a*) What is its inductance? (*b*) What is its reactance at 160 Hz?

Picture the Problem We can use $X_L = \omega L$ to find the inductance of the inductor at any frequency.

(*a*) Relate the reactance of the inductor to its inductance:

$$X_L = \omega L = 2\pi f L \Rightarrow L = \frac{X_L}{2\pi f}$$

Solve for and evaluate *L*:

$$L = \frac{100\,\Omega}{2\pi\left(80\,\text{s}^{-1}\right)} = 0.199\,\text{H} = \boxed{0.20\,\text{H}}$$

(*b*) At 160 Hz:

$$X_L = 2\pi\left(160\,\text{s}^{-1}\right)\left(0.199\,\text{H}\right) = \boxed{0.20\,\text{k}\Omega}$$

23 • At what frequency would the reactance of a 10-μF capacitor equal the reactance of a 1.0-μH inductor?

Picture the Problem We can equate the reactances of the capacitor and the inductor and then solve for the frequency.

Express the reactance of the inductor:

$$X_L = \omega L = 2\pi f L$$

Express the reactance of the capacitor:

$$X_C = \frac{1}{\omega C} = \frac{1}{2\pi f C}$$

Equate these reactances to obtain:

$$2\pi f L = \frac{1}{2\pi f C} \Rightarrow f = \frac{1}{2\pi}\sqrt{\frac{1}{LC}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{1}{\left(10\,\mu\text{F}\right)\left(1.0\,\mu\text{H}\right)}} = \boxed{50\,\text{kHz}}$$

24 • What is the reactance of a 1.00-nF capacitor at (*a*) 60.0 Hz, (*b*) 6.00 kHz, and (*c*) 6.00 MHz?

Picture the Problem We can use $X_C = 1/\omega C$ to find the reactance of the capacitor at any frequency.

Express the capacitive reactance as a function of *f*:

$$X_C = \frac{1}{\omega C} = \frac{1}{2\pi f C}$$

(*a*) At *f* = 60.0 Hz:

$$X_C = \frac{1}{2\pi\left(60.0\,\mathrm{s}^{-1}\right)\left(1.00\,\mathrm{nF}\right)} = \boxed{2.65\,\mathrm{M\Omega}}$$

(*b*) At *f* = 6.00 kHz:

$$X_C = \frac{1}{2\pi\left(6.00\,\mathrm{kHz}\right)\left(1.00\,\mathrm{nF}\right)} = \boxed{26.5\,\mathrm{k\Omega}}$$

(*c*) At *f* = 6.00 MHz:

$$X_C = \frac{1}{2\pi\left(6.00\,\mathrm{MHz}\right)\left(1.00\,\mathrm{nF}\right)} = \boxed{26.5\,\Omega}$$

25 • [SSM] A 20-Hz ac generator that produces a peak emf of 10 V is connected to a 20-μF capacitor. Find (*a*) the peak current and (*b*) the rms current.

Picture the Problem We can use $I_{\mathrm{peak}} = \mathcal{E}_{\mathrm{peak}}/X_C$ and $X_C = 1/\omega C$ to express I_{peak} as a function of $\mathcal{E}_{\mathrm{peak}}$, *f*, and *C*. Once we've evaluate I_{peak}, we can use $I_{\mathrm{rms}} = I_{\mathrm{peak}}/\sqrt{2}$ to find I_{rms}.

Express I_{peak} in terms of $\mathcal{E}_{\mathrm{peak}}$ and X_C:

$$I_{\mathrm{peak}} = \frac{\mathcal{E}_{\mathrm{peak}}}{X_C}$$

Express the capacitive reactance:

$$X_C = \frac{1}{\omega C} = \frac{1}{2\pi f C}$$

Substitute for X_C and simplify to obtain:

$$I_{\mathrm{peak}} = 2\pi f C\mathcal{E}_{\mathrm{peak}}$$

(*a*) Substitute numerical values and evaluate I_{peak}:

$$I_{\mathrm{peak}} = 2\pi\left(20\,\mathrm{s}^{-1}\right)\left(20\,\mu\mathrm{F}\right)\left(10\,\mathrm{V}\right) = 25.1\,\mathrm{mA} = \boxed{25\,\mathrm{mA}}$$

(*b*) Express I_{rms} in terms of I_{peak}:

$$I_{\mathrm{rms}} = \frac{I_{\mathrm{peak}}}{\sqrt{2}} = \frac{25.1\,\mathrm{mA}}{\sqrt{2}} = \boxed{18\,\mathrm{mA}}$$

26 • At what frequency is the reactance of a 10-μF capacitor (*a*) 1.00 Ω, (*b*) 100 Ω, and (*c*) 10.0 mΩ?

Picture the Problem We can use $X_C = 1/\omega C = 1/2\pi fC$ to relate the reactance of the capacitor to the frequency.

The reactance of the capacitor is given by:

$$X_C = \frac{1}{\omega C} = \frac{1}{2\pi fC} \Rightarrow f = \frac{1}{2\pi CX_C}$$

(*a*) Find f when $X_C = 1.00\ \Omega$:

$$f = \frac{1}{2\pi(10\ \mu\text{F})(1.00\ \Omega)} = \boxed{16\,\text{kHz}}$$

(*b*) Find f when $X_C = 100\ \Omega$:

$$f = \frac{1}{2\pi(10\ \mu\text{F})(100\ \Omega)} = \boxed{0.16\,\text{kHz}}$$

(*c*) Find f when $X_C = 10.0\ \text{m}\Omega$:

$$f = \frac{1}{2\pi(10\ \mu\text{F})(10.0\ \text{m}\Omega)} = \boxed{1.6\,\text{MHz}}$$

27 •• A circuit consists of two ideal ac generators and a 25-Ω resistor, all connected in series. The potential difference across the terminals of one of the generators is given by $V_1 = (5.0\ \text{V})\cos(\omega t - \alpha)$, and the potential difference across the terminals of the other generator is given by $V_2 = (5.0\ \text{V})\cos(\omega t + \alpha)$, where $\alpha = \pi/6$. (*a*) Use Kirchhoff's loop rule and a trigonometric identity to find the peak current in the circuit. (*b*) Use a phasor diagram to find the peak current in the circuit. (*c*) Find the current in the resistor if $\alpha = \pi/4$ and the amplitude of V_2 is increased from 5.0 V to 7.0 V.

Picture the Problem We can use the trigonometric identity

$$\cos\theta + \cos\phi = 2\cos\tfrac{1}{2}(\theta+\phi)\cos\tfrac{1}{2}(\theta-\phi)$$

to find the sum of the phasors V_1 and V_2 and then use this sum to express I as a function of time. In (*b*) we'll use a phasor diagram to obtain the same result and in (*c*) we'll use the phasor diagram appropriate to the given voltages to express the current as a function of time.

(*a*) Applying Kirchhoff's loop rule to the circuit yields:

$$V_1 + V_2 - IR = 0$$

Solve for I to obtain:

$$I = \frac{V_1 + V_2}{R}$$

Use the trigonometric identity $\cos\theta + \cos\phi = 2\cos\frac{1}{2}(\theta+\phi)\cos\frac{1}{2}(\theta-\phi)$ to find $V_1 + V_2$:

$$V_1 + V_2 = (5.0\,\text{V})[\cos(\omega t - \alpha) + \cos(\omega t + \alpha)] = (5\,\text{V})[2\cos\tfrac{1}{2}(2\omega t)\cos\tfrac{1}{2}(-2\alpha)]$$
$$= (10\,\text{V})\cos\frac{\pi}{6}\cos\omega t = (8.66\,\text{V})\cos\omega t$$

Substitute for $V_1 + V_2$ and R to obtain:

$$I = \frac{(8.66\,\text{V})\cos\omega t}{25\,\Omega} = (0.346\,\text{A})\cos\omega t$$
$$= (0.35\,\text{A})\cos\omega t$$

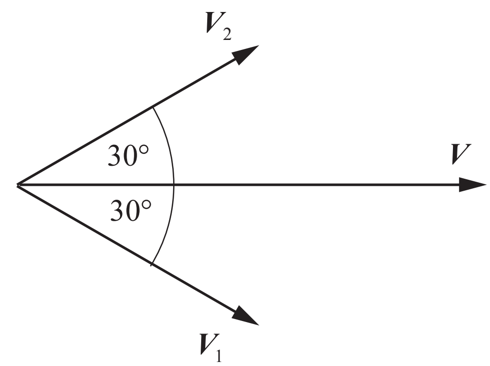
where

$$I_{\text{peak}} = \boxed{0.35\,\text{A}}$$

(b) Express the magnitude of the current in R:

$$|I| = \frac{|\vec{V}|}{R}$$

The phasor diagram for the voltages is shown to the right.



Use vector addition to find $|\vec{V}|$:

$$|\vec{V}| = 2|\vec{V}_1|\cos 30° = 2(5.0\,\text{V})\cos 30°$$
$$= 8.66\,\text{V}$$

Substitute for $|\vec{V}|$ and R to obtain:

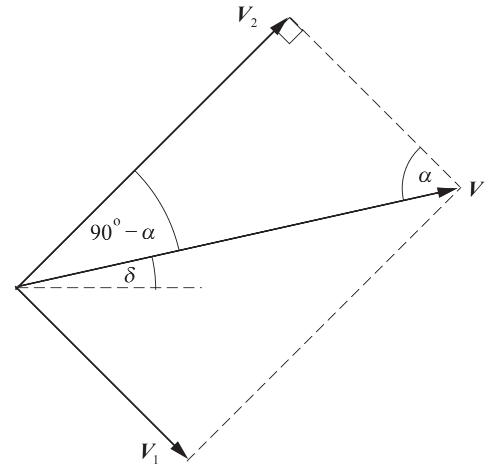
$$|I| = \frac{8.66\,\text{V}}{25\,\Omega} = 0.346\,\text{A}$$

and $I = (0.35\,\text{A})\cos\omega t$

where

$$I_{\text{peak}} = \boxed{0.35\,\text{A}}$$

(*c*) The phasor diagram is shown to the right. Note that the phase angle between $\vec{V}_1$ and $\vec{V}_2$ is now 90°.



Use the Pythagorean theorem to find $|\vec{V}|$:

$$|\vec{V}| = \sqrt{|\vec{V}_1|^2 + |\vec{V}_2|^2} = \sqrt{(5.0\text{ V})^2 + (7.0\text{ V})^2}$$
$$= 8.60\text{ V}$$

Express I as a function of t:

$$I = \frac{|\vec{V}|}{R}\cos(\omega t + \delta)$$

where

$$\delta = 45° - (90° - \alpha) = \alpha - 45°$$
$$= \tan^{-1}\left(\frac{7.0\text{ V}}{5.0\text{ V}}\right) - 45°$$
$$= 9.462° = 0.165\text{ rad}$$

Substitute numerical values and evaluate I:

$$I = \frac{8.60\text{ V}}{25\,\Omega}\cos(\omega t + 0.165\text{ rad})$$
$$= \boxed{(0.34\text{ A})\cos(\omega t + 0.17\text{ rad})}$$

Undriven Circuits Containing Capacitors, Resistors and Inductors

28 • (*a*) Show that $1/\sqrt{LC}$ has units of inverse seconds by substituting SI units for inductance and capacitance into the expression. (*b*) Show that $\omega_0 L/R$ (the expression for the *Q*-factor) is dimensionless by substituting SI units for angular frequency, inductance, and resistance into the expression.

Picture the Problem We can substitute the units of the various physical quantitities in $1/\sqrt{LC}$ and $Q = \omega_0 L/R$ to establish their units.

(*a*) Substitute the units for *L* and *C* in the expression $1/\sqrt{LC}$ and simplify to obtain:

$$\frac{1}{\sqrt{\text{H}\cdot\text{F}}}=\frac{1}{\sqrt{(\Omega\cdot\text{s})\left(\frac{\text{s}}{\Omega}\right)}}=\frac{1}{\sqrt{\text{s}^2}}=\boxed{\text{s}^{-1}}$$

(*b*) Substitute the units for ω_0, *L*, and *R* in the expression $Q=\omega_0 L/R$ and simplify to obtain:

$$\frac{\frac{1}{\text{s}}\cdot\frac{\text{V}\cdot\text{s}}{\text{A}}}{\frac{\text{V}}{\text{A}}}=\frac{\frac{1}{\text{s}}\cdot\frac{\text{V}\cdot\text{s}}{\text{A}}}{\frac{\text{V}}{\text{A}}}=1\Rightarrow\boxed{\text{no units}}$$

29 • **[SSM]** (*a*) What is the period of oscillation of an *LC* circuit consisting of an ideal 2.0-mH inductor and a 20-μF capacitor? (*b*) A circuit that oscillates consists solely of an 80-μF capacitor and a variable ideal inductor. What inductance is needed in order to tune this circuit to oscillate at 60 Hz?

Picture the Problem We can use $T=2\pi/\omega$ and $\omega=1/\sqrt{LC}$ to relate *T* (and hence *f*) to *L* and *C*.

(*a*) Express the period of oscillation of the *LC* circuit:

$$T=\frac{2\pi}{\omega}$$

For an *LC* circuit:

$$\omega=\frac{1}{\sqrt{LC}}$$

Substitute for ω to obtain:

$$T=2\pi\sqrt{LC}\qquad(1)$$

Substitute numerical values and evaluate *T*:

$$T=2\pi\sqrt{(2.0\,\text{mH})(20\,\mu\text{F})}=\boxed{1.3\,\text{ms}}$$

(*b*) Solve equation (1) for *L* to obtain:

$$L=\frac{T^2}{4\pi^2C}=\frac{1}{4\pi^2f^2C}$$

Substitute numerical values and evaluate *L*:

$$L=\frac{1}{4\pi^2\left(60\,\text{s}^{-1}\right)^2(80\,\mu\text{F})}=\boxed{88\,\text{mH}}$$

30 • An *LC* circuit has capacitance C_0 and inductance *L*. A second *LC* circuit has capacitance $\frac{1}{2}C_0$ and inductance 2*L*, and a third *LC* circuit has capacitance $2C_0$ and inductance $\frac{1}{2}L$. (*a*) Show that each circuit oscillates with the same frequency. (*b*) In which circuit would the peak current be greatest if the peak voltage across the capacitor in each circuit was the same?

Picture the Problem We can use the expression $f_0 = 1/2\pi\sqrt{LC}$ for the resonance frequency of an *LC* circuit to show that each circuit oscillates with the same frequency. In (*b*) we can use $I_{peak} = \omega Q_0$, where Q_0 is the charge of the capacitor at time zero, and the definition of capacitance $Q_0 = CV$ to express I_{peak} in terms of ω, *C* and *V*.

Express the resonance frequency for an *LC* circuit:

$$f_0 = \frac{1}{2\pi\sqrt{LC}}$$

(*a*) Express the product of *L* and C_0 for each circuit:

Circuit 1: $L_1C_1 = L_1C_0$,
Circuit 2: $L_2C_2 = (2L_1)(\frac{1}{2}C_0) = L_1C_1$,
and
Circuit 3: $L_3C_3 = (\frac{1}{2}L_1)(2C_0) = L_1C_1$

Because $L_1C_1 = L_2C_2 = L_3C_3$, the resonance frequencies of the three circuits are the same.

(*b*) Express I_{peak} in terms of the charge stored in the capacitor:

$$I_{peak} = \omega Q_0$$

Express Q_0 in terms of the capacitance of the capacitor and the potential difference across the capacitor:

$$Q_0 = CV$$

Substituting for Q_0 yields:

$$I_{peak} = \omega CV$$

or, for ω and *V* constant, $I_{peak} \propto C$.

Hence, the circuit with capacitance $2C_0$ has the greatest peak current.

31 •• A 5.0-μF capacitor is charged to 30 V and is then connected across an ideal 10-mH inductor. (*a*) How much energy is stored in the system? (*b*) What is the frequency of oscillation of the circuit? (*c*) What is the peak current in the circuit?

Picture the Problem We can use $U = \frac{1}{2}CV^2$ to find the energy stored in the electric field of the capacitor, $\omega_0 = 2\pi f_0 = 1/\sqrt{LC}$ to find f_0, and $I_{peak} = \omega Q_0$ and $Q_0 = CV$ to find I_{peak}.

(*a*) Express the energy stored in the system as a function of *C* and *V*:

$$U = \tfrac{1}{2}CV^2$$

Substitute numerical values and evaluate *U*:

$$U = \tfrac{1}{2}(5.0\,\mu\text{F})(30\,\text{V})^2 = \boxed{2.3\,\text{mJ}}$$

(*b*) Express the resonance frequency of the circuit in terms of *L* and *C*:

$$\omega_0 = 2\pi f_0 = \frac{1}{\sqrt{LC}} \Rightarrow f_0 = \frac{1}{2\pi\sqrt{LC}}$$

Substitute numerical values and evaluate f_0:

$$f_0 = \frac{1}{2\pi\sqrt{(10\,\text{mH})(5.0\,\mu\text{F})}} = 712\,\text{Hz}$$
$$= \boxed{0.71\,\text{kHz}}$$

(*c*) Express I_{peak} in terms of the charge stored in the capacitor:

$$I_{\text{peak}} = \omega Q_0$$

Express Q_0 in terms of the capacitance of the capacitor and the potential difference across the capacitor:

$$Q_0 = CV$$

Substituting for Q_0 yields:

$$I_{\text{peak}} = \omega CV$$

Substitute numerical values and evaluate I_{peak}:

$$I_{\text{peak}} = 2\pi\left(712\,\text{s}^{-1}\right)(5.0\,\mu\text{F})(30\,\text{V})$$
$$= \boxed{0.67\,\text{A}}$$

32 •• A coil with internal resistance can be modeled as a resistor and an ideal inductor in series. Assume that the coil has an internal resistance of 1.00 Ω and an inductance of 400 mH. A 2.00-μF capacitor is charged to 24.0 V and is then connected across coil. (*a*) What is the initial voltage across the coil? (*b*) How much energy is dissipated in the circuit before the oscillations die out? (*c*) What is the frequency of oscillation the circuit? (Assume the internal resistance is sufficiently small that has no impact on the frequency of the circuit.) (*d*) What is the quality factor of the circuit?

Picture the Problem In Part (*a*) we can apply Kirchhoff's loop rule to find the initial voltage across the coil. (*b*) The total energy lost via joule heating is the total energy initially stored in the capacitor. (*c*) The natural frequency of the circuit is given by $f_0 = 1/2\pi\sqrt{LC}$. In Part (*d*) we can use its definition to find the quality factor of the circuit.

(*a*) Application of Kirchhoff's loop rule leads us to conclude that the initial voltage across the coil is $\boxed{24.0\text{ V}}$.

(*b*) Because the ideal inductor can not dissipate energy as heat, all of the energy initially stored in the capacitor will be dissipated as joule heat in the resistor:

$$U = \frac{1}{2}CV^2 = \frac{1}{2}(2.00\,\mu\text{F})(24.0\text{ V})^2 = \boxed{0.576\text{ mJ}}$$

(*c*) The natural frequency of the circuit is:

$$f_0 = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(400\text{ mH})(2.00\,\mu\text{F})}} = \boxed{178\text{ Hz}}$$

(*d*) The quality factor of the circuit is given by:

$$Q = \frac{\omega_0 L}{R}$$

Substituting for ω_0 and simplifying yields:

$$Q = \frac{\frac{1}{\sqrt{LC}}L}{R} = \frac{1}{R}\sqrt{\frac{L}{C}}$$

Substitute numerical values and evaluate Q:

$$Q = \frac{1}{1.00\,\Omega}\sqrt{\frac{400\text{ mH}}{2.00\,\mu\text{F}}} = \boxed{447}$$

33 ••• [SSM] An inductor and a capacitor are connected, as shown in Figure 29-30. Initially, the switch is open, the left plate of the capacitor has charge Q_0. The switch is then closed. (*a*) Plot both Q versus t and I versus t on the same graph, and explain how it can be seen from these two plots that the current leads the charge by 90º. (*b*) The expressions for the charge and for the current are given by Equations 29-38 and 29-39, respectively. Use trigonometry and algebra to show that the current leads the charge by 90º.

Picture the Problem Let Q represent the instantaneous charge on the capacitor and apply Kirchhoff's loop rule to obtain the differential equation for the circuit. We can then solve this equation to obtain an expression for the charge on the capacitor as a function of time and, by differentiating this expression with respect

to time, an expression for the current as a function of time. We'll use a spreadsheet program to plot the graphs.

Apply Kirchhoff's loop rule to a clockwise loop just after the switch is closed:

$$\frac{Q}{C} + L\frac{dI}{dt} = 0$$

Because $I = dQ/dt$:

$$L\frac{d^2Q}{dt^2} + \frac{Q}{C} = 0 \text{ or } \frac{d^2Q}{dt^2} + \frac{1}{LC}Q = 0$$

The solution to this equation is:

$$Q(t) = Q_0 \cos(\omega t - \delta)$$

where $\omega = \sqrt{\frac{1}{LC}}$

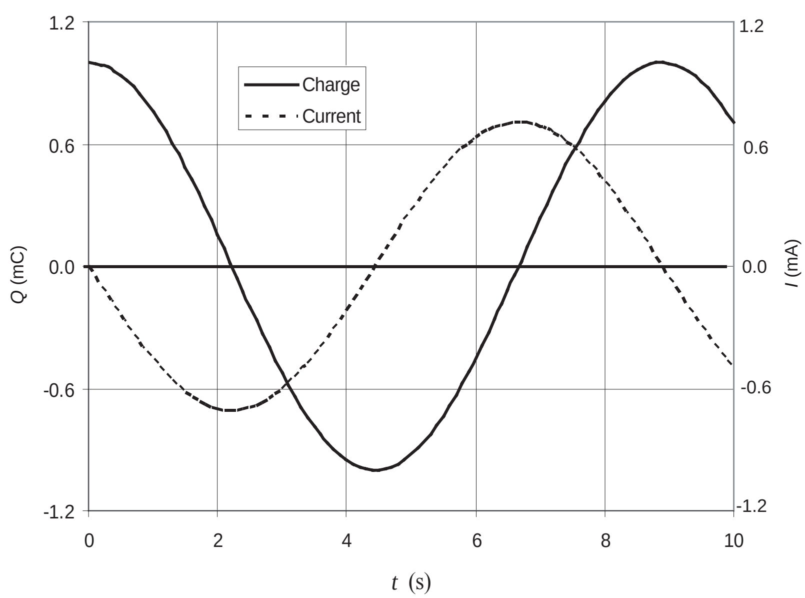
Because $Q(0) = Q_0$, $\delta = 0$ and:

$$Q(t) = Q_0 \cos \omega t$$

The current in the circuit is the derivative of Q with respect to t:

$$I = \frac{dQ}{dt} = \frac{d}{dt}\left[Q_0 \cos \omega t\right] = -\omega Q_0 \sin \omega t$$

(a) A spreadsheet program was used to plot the following graph showing both the charge on the capacitor and the current in the circuit as functions of time. L, C, and Q_0 were all arbitrarily set equal to one to obtain these graphs. Note that the current leads the charge by one-fourth of a cycle or 90°.



(b) The equation for the current is:

$$I = -\omega Q_0 \sin \omega t \qquad (1)$$

The sine and cosine functions are related through the identity:

$$-\sin\theta = \cos\left(\theta + \frac{\pi}{2}\right)$$

Use this identity to rewrite equation (1):

$$I = -\omega Q_0 \sin\omega t = \boxed{\omega Q_0 \cos\left(\omega t + \frac{\pi}{2}\right)}$$

Thus, the current leads the charge by 90°.

Driven *RL* Circuits

34 •• A circuit consists of a resistor, an ideal 1.4-H inductor and an ideal 60-Hz generator, all connected in series. The rms voltage across the resistor is 30 V and the rms voltage across the inductor is 40 V. (*a*) What is the resistance of the resistor? (*b*) What is the peak emf of the generator?

Picture the Problem We can express the ratio of V_R to V_L and solve this expression for the resistance *R* of the circuit. In (*b*) we can use the fact that, in an *LR* circuit, V_L leads V_R by 90° to find the ac input voltage.

(*a*) Express the potential differences across *R* and *L* in terms of the common current through these components:

$$V_L = IX_L = I\omega L$$

and

$$V_R = IR$$

Divide the second of these equations by the first to obtain:

$$\frac{V_R}{V_L} = \frac{IR}{I\omega L} = \frac{R}{\omega L} \Rightarrow R = \left(\frac{V_R}{V_L}\right)\omega L$$

Substitute numerical values and evaluate *R*:

$$R = \left(\frac{30\,\text{V}}{40\,\text{V}}\right)2\pi\left(60\,\text{s}^{-1}\right)(1.4\,\text{H}) = \boxed{0.40\,\text{k}\Omega}$$

(*b*) Because V_R leads V_L by 90° in an *LR* circuit:

$$V_{\text{peak}} = \sqrt{2}V_{\text{rms}} = \sqrt{2}\sqrt{V_R^2 + V_L^2}$$

Substitute numerical values and evaluate V_{peak}:

$$V_{\text{peak}} = \sqrt{2}\sqrt{(30\,\text{V})^2 + (40\,\text{V})^2} = \boxed{71\,\text{V}}$$

35 •• **[SSM]** A coil that has a resistance of 80.0 Ω has an impedance of 200 Ω when driven at a frequency of 1.00 kHz. What is the inductance of the coil?

Picture the Problem We can solve the expression for the impedance in an *LR* circuit for the inductive reactance and then use the definition of X_L to find *L*.

Express the impedance of the coil in terms of its resistance and inductive reactance:

$$Z=\sqrt{R^2+X_L^2}$$

Solve for X_L to obtain:

$$X_L=\sqrt{Z^2-R^2}$$

Express X_L in terms of L:

$$X_L=2\pi fL$$

Equate these two expressions to obtain:

$$2\pi fL=\sqrt{Z^2-R^2}\Rightarrow L=\frac{\sqrt{Z^2-R^2}}{2\pi f}$$

Substitute numerical values and evaluate L:

$$L=\frac{\sqrt{(200\,\Omega)^2-(80.0\,\Omega)^2}}{2\pi(1.00\,\text{kHz})}=\boxed{29.2\,\text{mH}}$$

36 •• A two conductor transmission line simultaneously carries a superposition of two voltage signals, so the potential difference between the two conductors is given by $V = V_1 + V_2$, where $V_1 = (10.0\text{ V})\cos(\omega_1 t)$ and $V_2 = (10.0\text{ V})\cos(\omega_2 t)$, where $\omega_1 = 100$ rad/s and $\omega_2 = 10\,000$ rad/s. A 1.00 H inductor and a 1.00 kΩ shunt resistor are inserted into the transmission line as shown in Figure 29-31. (Assume that the output is connected to a load that draws only an insignificant amount of current.) (*a*) What is the voltage (V_{out}) at the output of the transmission line? (*b*) What is the ratio of the low-frequency amplitude to the high-frequency amplitude at the output?

Picture the Problem We can express the two output voltage signals as the product of the current from each source and R = 1.00 kΩ. We can find the currents due to each source using the given voltage signals and the definition of the impedance for each of them.

(*a*) Express the voltage signals observed at the output side of the transmission line in terms of the potential difference across the resistor:

$$V_{1,\text{out}}=I_1R$$

and

$$V_{2,\text{out}}=I_2R$$

Evaluate I_1 and I_2:

$$I_1 = \frac{V_1}{Z_1} = \frac{(10.0\,\text{V})\cos 100t}{\sqrt{(1.00\,\text{k}\Omega)^2 + \left[(100\,\text{s}^{-1})(1.00\,\text{H})\right]^2}} = (9.95\,\text{mA})\cos 100t$$

and

$$I_2 = \frac{V_2}{Z_2} = \frac{(10.0\,\text{V})\cos 10^4 t}{\sqrt{(1.00\,\text{k}\Omega)^2 + \left[(10^4\,\text{s}^{-1})(1.00\,\text{H})\right]^2}} = (0.995\,\text{mA})\cos 10^4 t$$

Substitute for I_1 and I_2 to obtain:

$$V_{1,\,\text{out}} = (1.00\,\text{k}\Omega)(9.95\,\text{mA})\cos 100t = \boxed{(9.95\,\text{V})\cos 100t}$$

where $\omega_1 = 100$ rad/s and $\omega_2 = 10\,000$ rad/s.

and

$$V_{2,\,\text{out}} = (1.00\,\text{k}\Omega)(0.995\,\text{mA})\cos 10^4 t = \boxed{(0.995\,\text{V})\cos 10^4 t}$$

(*b*) Express the ratio of $V_{1,\text{out}}$ to $V_{2,\text{out}}$:

$$\frac{V_{1,\,\text{out}}}{V_{2,\,\text{out}}} = \frac{9.95\,\text{V}}{0.995\,\text{V}} = \boxed{10:1}$$

37 •• A coil is connected to a 120-V rms, 60-Hz line. The average power supplied to the coil is 60 W, and the rms current is 1.5 A. Find (*a*) the power factor, (*b*) the resistance of the coil, and (*c*) the inductance of the coil. (*d*) Does the current lag or lead the voltage? Explain your answer. (*e*) Support your answer to Part (*d*) by determining the phase angle.

Picture the Problem The average power supplied to coil is related to the power factor by $P_{\text{av}} = \mathcal{E}_{\text{rms}} I_{\text{rms}} \cos\delta$. In (*b*) we can use $P_{\text{av}} = I_{\text{rms}}^2 R$ to find *R*. Because the inductance *L* is related to the resistance *R* and the phase angle δ according to $X_L = \omega L = R\tan\delta$, we can use this relationship to find the resistance of the coil. Finally, we can decide whether the current leads or lags the voltage by noting that the circuit is inductive.

(*a*) Express the average power supplied to the coil in terms of the power factor of the circuit:

$$P_{\text{av}} = \mathcal{E}_{\text{rms}} I_{\text{rms}} \cos\delta \Rightarrow \cos\delta = \frac{P_{\text{av}}}{\mathcal{E}_{\text{rms}} I_{\text{rms}}}$$

Substitute numerical values and evaluate $\cos\delta$:

$$\cos\delta = \frac{60\,\text{W}}{(120\,\text{V})(1.5\,\text{A})} = 0.333 = \boxed{0.33}$$

(*b*) Express the power supplied by the source in terms of the resistance of the coil:

$$P_{av} = I_{rms}^2 R \Rightarrow R = \frac{P_{av}}{I_{rms}^2}$$

Substitute numerical values and evaluate *R*:

$$R = \frac{60\ \text{W}}{(1.5\ \text{A})^2} = 26.7\ \Omega = \boxed{27\ \Omega}$$

(*c*) Relate the inductive reactance to the resistance and phase angle:

$$X_L = \omega L = R\tan\delta$$

Solving for *L* yields:

$$L = \frac{R\tan\delta}{\omega} = \frac{R\tan\left[\cos^{-1}(0.333)\right]}{2\pi f}$$

Substitute numerical values and evaluate *L*:

$$L = \frac{(26.7\ \Omega)\tan(70.5°)}{2\pi(60\ \text{s}^{-1})} = \boxed{0.20\ \text{H}}$$

(*d*) Evaluate X_L:

$$X_L = (26.7\ \Omega)\tan(70.5°) = 75.4\ \Omega$$

Because the circuit is inductive, the current lags the voltage.

(*e*) From Part (*a*):

$$\delta = \cos^{-1}(0.333) = \boxed{71°}$$

38 •• A 36-mH inductor that has a resistance of 40 Ω is connected to an ideal ac voltage source whose output is given by $\mathcal{E}$ = (345 V) cos(150πt), where *t* is in seconds. Determine (*a*) the peak current in the circuit, (*b*) the peak and rms voltages across the inductor, (*c*) the average power dissipation, and (*d*) the peak and average magnetic energy stored in the inductor.

Picture the Problem (*a*) We can use $I_{peak} = \mathcal{E}_{peak} \Big/ \sqrt{R^2 + (\omega L)^2}$ and $V_{L,\,peak} = I_{peak} X_L = \omega L I_{peak}$ to find the peak current in the circuit and the peak voltage across the inductor. (*b*) Once we've found $V_{L,\,peak}$ we can find $V_{L,\,rms}$ using $V_{L,\,rms} = V_{L,\,peak} \big/ \sqrt{2}$. (*c*) We can use $P_{av} = \frac{1}{2} I_{rms}^2 R$ to find the average power dissipation, and (*d*) $U_{L,\,peak} = \frac{1}{2} L I_{peak}^2$ to find the peak and average magnetic energy stored in the inductor. The average energy stored in the magnetic field of the inductor can be found using $U_{L,av} = \int P_{av}\,dt$.

(*a*) Apply Kirchhoff's loop rule to the circuit to obtain:

$$\mathcal{E} - IZ = 0 \Rightarrow I = \frac{\mathcal{E}}{Z} = \frac{\mathcal{E}}{\sqrt{R^2 + (\omega L)^2}}$$

Substitute numerical values and evaluate *I*:

$$I = \frac{(345\,\text{V})\cos(150\pi t)}{\sqrt{(40\,\Omega)^2 + \left[(150\pi\,\text{s}^{-1})(36\,\text{mH})\right]^2}} = (7.94\,\text{A})\cos(150\pi t)$$

and $I_{\text{peak}} = \boxed{7.9\,\text{A}}$.

(*b*) Because $\mathcal{E}$ = (345 V) cos(150πt) :

$$V_{L,\,\text{peak}} = \boxed{345\,\text{V}}$$

Find $V_{L,\text{rms}}$ from $V_{L,\,\text{peak}}$:

$$V_{L,\text{rms}} = \frac{V_{L,\,\text{peak}}}{\sqrt{2}} = \frac{345\,\text{V}}{\sqrt{2}} = \boxed{244\,\text{V}}$$

(*c*) Relate the average power dissipation to I_{peak} and *R*:

$$P_{\text{av}} = I_{\text{rms}}^2 R = \left(\frac{I_{\text{peak}}}{\sqrt{2}}\right)^2 R = \tfrac{1}{2} I_{\text{peak}}^2 R$$

Substitute numerical values and evaluate P_{av} :

$$P_{\text{av}} = \tfrac{1}{2}(7.94\,\text{A})^2(40\,\Omega) = \boxed{1.3\,\text{kW}}$$

(*d*) The maximum energy stored in the magnetic field of the inductor is:

$$U_{L,\,\text{peak}} = \tfrac{1}{2} L I_{\text{peak}}^2 = \tfrac{1}{2}(36\,\text{mH})(7.94\,\text{A})^2 = \boxed{1.1\,\text{J}}$$

The definition of $U_{L,\text{av}}$ is:

$$U_{L,\text{av}} = \frac{1}{T}\int_0^T U(t)\,dt$$

U(*t*) is given by:

$$U(t) = \frac{1}{2} L[I(t)]^2$$

Substitute for *U*(*t*) to obtain:

$$U_{L,\text{av}} = \frac{L}{2T}\int_0^T [I(t)]^2\,dt$$

Evaluating the integral yields:

$$U_{L,\text{av}} = \frac{L}{2T}\left[\frac{1}{2} I_{\text{peak}}^2\right] T = \frac{1}{4} L I_{\text{peak}}^2$$

Substitute numerical values and evaluate $U_{L,\text{av}}$:

$$U_{L,\text{av}} = \frac{1}{4}(36\,\text{mH})(7.94\,\text{A})^2 = \boxed{0.57\,\text{J}}$$

39 •• **[SSM]** A coil that has a resistance R and an inductance L has a power factor equal to 0.866 when driven at a frequency of 60 Hz. What is the coil's power factor it is driven at 240 Hz?

Picture the Problem We can use the definition of the power factor to find the relationship between X_L and R when the coil is driven at a frequency of 60 Hz and then use the definition of X_L to relate the inductive reactance at 240 Hz to the inductive reactance at 60 Hz. We can then use the definition of the power factor to determine its value at 240 Hz.

Using the definition of the power factor, relate R and X_L:

$$\cos\delta = \frac{R}{Z} = \frac{R}{\sqrt{R^2 + X_L^2}} \qquad (1)$$

Square both sides of the equation to obtain:

$$\cos^2\delta = \frac{R^2}{R^2 + X_L^2}$$

Solve for $X_L^2(60\,\text{Hz})$:

$$X_L^2(60\,\text{Hz}) = R^2\left(\frac{1}{\cos^2\delta} - 1\right)$$

Substitute for $\cos\delta$ and simplify to obtain:

$$X_L^2(60\,\text{Hz}) = R^2\left(\frac{1}{(0.866)^2} - 1\right) = \tfrac{1}{3}R^2$$

Use the definition of X_L to obtain:

$$X_L^2(f) = 4\pi f^2 L^2 \text{ and } X_L^2(f') = 4\pi f'^2 L^2$$

Dividing the second of these equations by the first and simplifying yields:

$$\frac{X_L^2(f')}{X_L^2(f)} = \frac{4\pi f'^2 L^2}{4\pi f^2 L^2} = \frac{f'^2}{f^2}$$

or

$$X_L^2(f') = \left(\frac{f'}{f}\right)^2 X_L^2(f)$$

Substitute numerical values to obtain:

$$X_L^2(240\,\text{Hz}) = \left(\frac{240\,\text{s}^{-1}}{60\,\text{s}^{-1}}\right)^2 X_L^2(60\,\text{Hz})$$

$$= 16\left(\frac{1}{3}R^2\right) = \frac{16}{3}R^2$$

Substitute in equation (1) to obtain:

$$(\cos\delta)_{240\,\text{Hz}} = \frac{R}{\sqrt{R^2 + \frac{16}{3}R^2}} = \sqrt{\frac{3}{19}} = \boxed{0.397}$$

40 •• A resistor and an inductor are connected in parallel across an ideal ac voltage source whose output is given by $\mathcal{E} = \mathcal{E}_{peak}\cos\omega t$ as shown in Figure 29-32. Show that (*a*) the current in the resistor is given by $I_R = \mathcal{E}_{peak}/R\cos\omega t$, (*b*) the current in the inductor is given by $I_L = \mathcal{E}_{peak}/X_L\cos(\omega t - 90°)$, and (*c*) the current in the voltage source is given by $I = I_R + I_L = I_{peak}\cos(\omega t - \delta)$, where $I_{peak} = \mathcal{E}_{max}/Z$.

Picture the Problem Because the resistor and the inductor are connected in parallel, the voltage drops across them are equal. Also, the total current is the sum of the current through the resistor and the current through the inductor. Because these two currents are not in phase, we'll need to use phasors to calculate their sum. The amplitudes of the applied voltage and the currents are equal to the magnitude of the phasors. That is $\left|\vec{\boldsymbol{\mathcal{E}}}\right| = \mathcal{E}_{peak}$, $\left|\vec{\boldsymbol{I}}\right| = I_{peak}$, $\left|\vec{\boldsymbol{I}}_R\right| = I_{R,\,peak}$, and $\left|\vec{\boldsymbol{I}}_L\right| = I_{L,\,peak}$.

(*a*) The ac source applies a voltage given by $\mathcal{E} = \mathcal{E}_{peak}\cos\omega t$. Thus, the voltage drop across both the load resistor and the inductor is:

$$\mathcal{E}_{peak}\cos\omega t = I_R R$$

The current in the resistor is in phase with the applied voltage:

$$I_R = I_{R,\,peak}\cos\omega t$$

Because $I_{R,\,peak} = \dfrac{\mathcal{E}_{peak}}{R}$:

$$I_R = \boxed{\frac{\mathcal{E}_{peak}}{R}\cos\omega t}$$

(*b*) The current in the inductor lags the applied voltage by 90°:

$$I_L = I_{L,\,peak}\cos(\omega t - 90°)$$

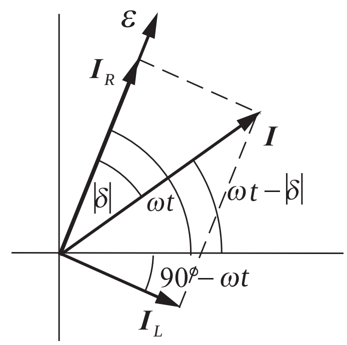
Because $I_{L,\,peak} = \dfrac{\mathcal{E}_{peak}}{X_L}$:

$$I_L = \boxed{\frac{\mathcal{E}_{peak}}{X_L}\cos(\omega t - 90°)}$$

(*c*) The net current I is the sum of the currents through the parallel branches:

$$I = I_R + I_L$$

Draw the phasor diagram for the circuit. The projections of the phasors onto the horizontal axis are the instantaneous values. The current in the resistor is in phase with the applied voltage, and the current in the inductor lags the applied voltage by 90°. The net current phasor is the sum of the branch current phasors $\left(\vec{I} = \vec{I}_L + \vec{I}_R\right)$.



The peak current through the parallel combination is equal to $\mathcal{E}_{\text{peak}}/Z$, where Z is the impedance of the combination:

$$I = I_{\text{peak}} \cos(\omega t - |\delta|),$$

where $I_{\text{peak}} = \dfrac{\mathcal{E}_{\text{peak}}}{Z}$

From the phasor diagram we have:

$$I_{\text{peak}}^2 = I_{R,\,\text{peak}}^2 + I_{L,\,\text{peak}}^2$$

$$= \left(\frac{\mathcal{E}_{\text{peak}}}{R}\right)^2 + \left(\frac{\mathcal{E}_{\text{peak}}}{X_{\text{L}}}\right)^2$$

$$= \mathcal{E}_{\text{peak}}^2\left(\frac{1}{R^2} + \frac{1}{X_{\text{L}}^2}\right) = \frac{\mathcal{E}_{\text{peak}}^2}{Z^2}$$

where $\dfrac{1}{Z^2} = \dfrac{1}{R^2} + \dfrac{1}{X_L^2}$

.

Solving for I_{peak} yields:

$$I_{\text{peak}} = \boxed{\frac{\mathcal{E}_{\text{peak}}}{Z}} \text{ where } Z^{-2} = R^{-2} + X_L^{-2}$$

From the phasor diagram:

$$I = \boxed{I_{\text{peak}} \cos(\omega t - |\delta|)}$$

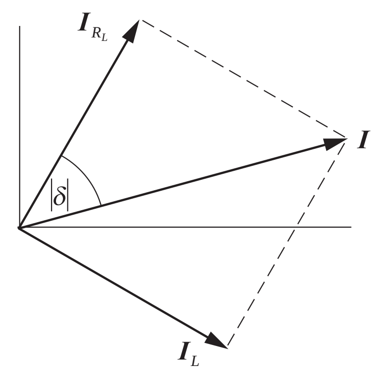
where

$$\tan|\delta| = \frac{I_{L,\,\text{peak}}}{I_{R,\,\text{peak}}} = \frac{\dfrac{\mathcal{E}_{\text{peak}}}{X_L}}{\dfrac{\mathcal{E}_{\text{peak}}}{R}} = \boxed{\frac{R}{X_L}}$$

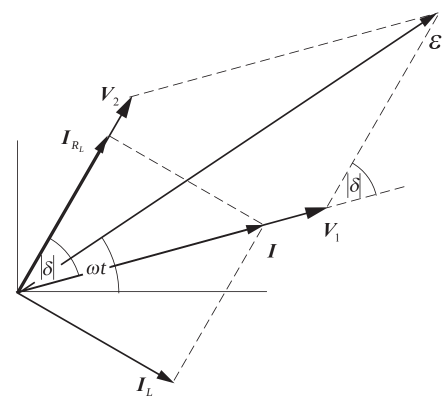
41 •• **[SSM]** Figure 29-33 shows a load resistor that has a resistance of $R_L = 20.0\ \Omega$ connected to a high-pass filter consisting of an inductor that has inductance $L = 3.20\text{-mH}$ and a resistor that has resistance $R = 4.00\text{-}\Omega$. The output of the ideal ac generator is given by $\mathcal{E} = (100\text{ V})\cos(2\pi ft)$. Find the rms currents in all three branches of the circuit if the driving frequency is (*a*) 500 Hz and (*b*) 2000 Hz. Find the fraction of the total average power supplied by the ac generator that is delivered to the load resistor if the frequency is (*c*) 500 Hz and (*d*) 2000 Hz.

Picture the Problem $\mathcal{E} = V_1 + V_2$, where V_1 is the voltage drop across R and V_2 is the voltage drop across the parallel combination of L and R_L. $\vec{\boldsymbol{\varepsilon}} = \vec{\boldsymbol{V}}_1 + \vec{\boldsymbol{V}}_2$ is the relation for the phasors. For the parallel combination $\vec{\boldsymbol{I}} = \vec{\boldsymbol{I}}_{R_L} + \vec{\boldsymbol{I}}_L$. Also, V_1 is in phase with I and V_2 is in phase with I_{R_L}. First draw the phasor diagram for the currents in the parallel combination, then add the phasors for the voltages to the diagram.

The phasor diagram for the currents in the circuit is:



Adding the voltage phasors to the diagram gives:



The maximum current in the inductor, $I_{2,\text{peak}}$, is given by:

$$I_{2,\text{peak}} = \frac{V_{2,\text{peak}}}{Z_2} \tag{1}$$

where $Z_2^{-2} = R_L^{-2} + X_L^{-2}$ (2)

$\tan|\delta|$ is given by:

$$\tan|\delta| = \frac{I_{L,\text{peak}}}{I_{R,\text{peak}}} = \frac{V_{2,\text{peak}}/X_\text{L}}{V_{2,\text{peak}}/R_\text{L}} = \frac{R_L}{X_L} = \frac{R_L}{\omega L} = \frac{R_L}{2\pi f L}$$

Solve for $|\delta|$ to obtain:

$$|\delta| = \tan^{-1}\left(\frac{R_\text{L}}{2\pi f L}\right) \tag{3}$$

Apply the law of cosines to the triangle formed by the voltage phasors to obtain:

$$\mathcal{E}_{\text{peak}}^2 = V_{1,\,\text{peak}}^2 + V_{2,\,\text{peak}}^2 + 2V_{1,\,\text{peak}}V_{2,\,\text{peak}}\cos|\delta|$$

or

$$I_{\text{peak}}^2 Z^2 = I_{\text{peak}}^2 R^2 + I_{\text{peak}}^2 Z_2^2 + 2I_{\text{peak}} R I_{\text{peak}} Z_2 \cos|\delta|$$

Dividing out the current squared yields:

$$Z^2 = R^2 + Z_2^2 + 2RZ_2\cos|\delta|$$

Solving for Z yields:

$$Z = \sqrt{R^2 + Z_2^2 + 2RZ_2\cos|\delta|} \quad (4)$$

The maximum current I_{peak} in the circuit is given by:

$$I_{\text{peak}} = \frac{\mathcal{E}_{\text{peak}}}{Z} \quad (5)$$

I_{rms} is related to I_{peak} according to:

$$I_{\text{rms}} = \frac{1}{\sqrt{2}} I_{\text{peak}} \quad (6)$$

(*a*) Substitute numerical values in equation (3) and evaluate $|\delta|$:

$$|\delta| = \tan^{-1}\left(\frac{20.0\,\Omega}{2\pi(500\,\text{Hz})(3.20\,\text{mH})}\right) = \tan^{-1}\left(\frac{20.0\,\Omega}{10.053\,\Omega}\right) = 63.31°$$

Solving equation (2) for Z_2 yields:

$$Z_2 = \frac{1}{\sqrt{R_L^{-2} + X_L^{-2}}}$$

Substitute numerical values and evaluate Z_2:

$$Z_2 = \frac{1}{\sqrt{(20.0\,\Omega)^{-2} + (10.053\,\Omega)^{-2}}} = 8.982\,\Omega$$

Substitute numerical values and evaluate Z:

$$Z = \sqrt{(4.00\,\Omega)^2 + (8.982\,\Omega)^2 + 2(4.00\,\Omega)(8.982\,\Omega)\cos 63.31°} = 11.36\,\Omega$$

Substitute numerical values in equation (5) and evaluate I_{peak}:

$$I_{\text{peak}} = \frac{100\,\text{V}}{11.36\,\Omega} = 8.806\,\text{A}$$

Substitute for I_{peak} in equation (6) and evaluate I_{rms}:

$$I_{\text{rms}} = \frac{1}{\sqrt{2}}(8.806\,\text{A}) = \boxed{6.23\,\text{A}}$$

The maximum and rms values of V_2 are given by:

$$V_{2,\,\text{peak}} = I_{\text{peak}} Z_2 = (8.806\,\text{A})(8.982\,\Omega) = 79.095\,\text{V}$$

and

$$V_{2,\text{rms}} = \frac{1}{\sqrt{2}} V_{2,\,\text{peak}} = \frac{1}{\sqrt{2}}(79.095\,\text{V}) = 55.929\,\text{V}$$

The rms values of $I_{R_L,\text{rms}}$ and $I_{L,\text{rms}}$ are:

$$I_{R_L,\text{rms}} = \frac{V_{2,\text{rms}}}{R_L} = \frac{55.929\,\text{V}}{20.0\,\Omega} = \boxed{2.80\,\text{A}}$$

and

$$I_{L,\text{rms}} = \frac{V_{2,\text{rms}}}{X_L} = \frac{55.929\,\text{V}}{10.053\,\Omega} = \boxed{5.56\,\text{A}}$$

(*b*) Proceed as in (*a*) with f = 2000 Hz to obtain:

$X_L = 40.2\,\Omega$, $|\delta| = 26.4°$, $Z_2 = 17.9\,\Omega$, $Z = 21.6\,\Omega$, $I_{\text{peak}} = 4.64\,\text{A}$, and $I_{\text{rms}} = \boxed{3.28\,\text{A}}$, $V_{2,\text{max}} = 83.0\,\text{V}$, $V_{2,\text{rms}} = 58.7\,\text{V}$, $I_{R_L,\text{rms}} = \boxed{2.94\,\text{A}}$, and $I_{L,\text{rms}} = \boxed{1.46\,\text{A}}$

(*c*) The power delivered by the ac source equals the sum of the power dissipated in the two resistors. The fraction of the total power delivered by the source that is dissipated in load resistor is given by:

$$\frac{P_{R_L}}{P_{R_L} + P_R} = \left(1 + \frac{P_R}{P_{R_L}}\right)^{-1} = \left(1 + \frac{I_{\text{rms}}^2 R}{I_{R_L,\text{rms}}^2 R_L}\right)^{-1}$$

Substitute numerical values for f = 500 Hz to obtain:

$$\left.\frac{P_{R_L}}{P_{R_L} + P_R}\right|_{f=500\,\text{Hz}} = \left(1 + \frac{(6.23\,\text{A})^2(4.00\,\Omega)}{(2.80\,\text{A})^2(20.0\,\Omega)}\right)^{-1} = 0.502 = \boxed{50.2\%}$$

(*d*) Substitute numerical values for f = 2000 Hz to obtain:

$$\left.\frac{P_{R_L}}{P_{R_L}+P_R}\right|_{f=2000\,\text{Hz}}=\left(1+\frac{(3.28\,\text{A})^2(4.00\,\Omega)}{(2.94\,\text{A})^2(20.0\,\Omega)}\right)^{-1}=0.800=\boxed{80.0\%}$$

42 •• An ideal ac voltage source whose emf $\mathcal{E}_1$ is given by (20 V) cos($2\pi ft$) and an ideal battery whose emf $\mathcal{E}_2$ is 16 V are connected to a combination of two resistors and an inductor (Figure 29-34), where R_1 = 10 Ω, R_2 = 8.0 Ω, and L = 6.0 mH. Find the average power delivered to each resistor if (*a*) the driving frequency is 100 Hz, (*b*) the driving frequency is 200 Hz, and (*c*) the driving frequency is 800 Hz.

Picture the Problem We can treat the ac and dc components separately. For the dc component, L acts like a short circuit. Let $\mathcal{E}_{1,\text{ peak}}$ denote the peak value of the voltage supplied by the ac voltage source. We can use $P=\mathcal{E}_2^2/R$ to find the power dissipated in the resistors by the current from the ideal battery. We'll apply Kirchhoff's loop rule to the loop including L, R_1, and R_2 to derive an expression for the average power delivered to each resistor by the ac voltage source.

(*a*) The total power delivered to R_1 and R_2 is:

$$P_1=P_{1,\text{ dc}}+P_{1,\text{ ac}} \qquad (1)$$

and

$$P_2=P_{2,\text{ dc}}+P_{2,\text{ ac}} \qquad (2)$$

The dc power delivered to the resistors whose resistances are R_1 and R_2 is:

$$P_{1,\text{dc}}=\frac{\mathcal{E}_2^2}{R_1}\text{ and }P_{2,\text{dc}}=\frac{\mathcal{E}_2^2}{R_2}$$

Express the average ac power delivered to R_1:

$$P_{1,\text{ac}}=\frac{\mathcal{E}_{1,\text{ rms}}^2}{R_1}=\frac{\mathcal{E}_{1,\text{ peak}}^2}{2R_1}$$

Apply Kirchhoff's loop rule to a clockwise loop that includes R_1, L, and R_2:

$$R_1I_1-Z_2I_2=0$$

Solving for I_2 yields:

$$I_2=\frac{R_1}{Z_2}I_1=\frac{R_1}{Z_2}\frac{\mathcal{E}_{1,\text{ peak}}}{R_1}=\frac{\mathcal{E}_{1,\text{ peak}}}{Z_2}$$

Express the average ac power delivered to R_2:

$$P_{2,\,\text{ac}} = \tfrac{1}{2} I_{2,\,\text{rms}}^2 R_2 = \tfrac{1}{2}\left(\frac{\mathcal{E}_{1,\,\text{peak}}}{Z_2}\right)^2 R_2 = \frac{\mathcal{E}_{1,\,\text{peak}}^2 R_2}{2Z_2^2}$$

Substituting in equations (1) and (2) yields:

$$P_1 = \frac{\mathcal{E}_2^2}{R_1} + \frac{\mathcal{E}_{1,\,\text{peak}}^2}{2R_1}$$

and

$$P_2 = \frac{\mathcal{E}_2^2}{R_2} + \frac{\mathcal{E}_{1,\,\text{peak}}^2 R_2}{2Z_2^2}$$

Substitute numerical values and evaluate P_1:

$$P_1 = \frac{(16\,\text{V})^2}{10\,\Omega} + \frac{(20\,\text{V})^2}{2(10\,\Omega)} = \boxed{46\ \text{W}}$$

Substitute numerical values and evaluate P_2:

$$P_2 = \frac{(16\,\text{V})^2}{8.0\,\Omega} + \frac{(20\,\text{V})^2(8.0\,\Omega)}{2\left[(8.0\,\Omega)^2 + \left(2\pi\{100\,\text{s}^{-1}\}\{6.0\,\text{mH}\}\right)^2\right]} = \boxed{52\ \text{W}}$$

(*b*) Proceed as in (*a*) to evaluate P_1 and P_2 with $f = 200$ Hz:

$$P_1 = 25.6\,\text{W} + 20.0\,\text{W} = \boxed{46\,\text{W}}$$

$$P_2 = 32.0\,\text{W} + 13.2\,\text{W} = \boxed{45\,\text{W}}$$

(*c*) Proceed as in (*a*) to evaluate P_1 and P_2 with $f = 800$ Hz:

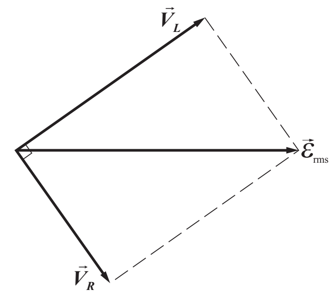
$$P_1 = 25.6\,\text{W} + 20.0\,\text{W} = \boxed{46\,\text{W}}$$

$$P_2 = 32.0\,\text{W} + 1.64\,\text{W} = \boxed{34\,\text{W}}$$

43 •• An ac circuit contains a resistor and an ideal inductor connected in series. The voltage rms drop across this series combination is 100-V and the rms voltage drop across the inductor alone is 80 V. What is the rms voltage drop across the resistor?

Picture the Problem We can use the phasor diagram for an *RL* circuit to find the voltage across the resistor.

The phasor diagram for the voltages in the circuit is shown to the right:



Use the Pythagorean theorem to express V_R:

$$V_R = \sqrt{\mathcal{E}_{\rm rms}^2 - V_L^2}$$

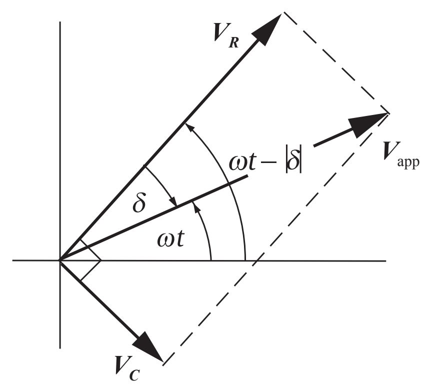
Substitute numerical values and evaluate V_R:

$$V_R = \sqrt{(100\,\text{V})^2 - (80\,\text{V})^2} = \boxed{60\,\text{V}}$$

Filters and Rectifiers

44 •• The circuit shown in Figure 29-35 is called an *RC high-pass filter* because it transmits input voltage signals that have high frequencies with greater amplitude than it transmits input voltage signals that have low frequencies. If the input voltage is given by $V_{\rm in} = V_{\rm in\,peak}\cos\omega t$, show that the output voltage is $V_{\rm out} = V_{\rm H}\cos(\omega t - \delta)$ where $V_{\rm H} = V_{\rm in\,peak}\big/\sqrt{1+(\omega RC)^{-2}}$. (Assume that the output is connected to a load that draws only an insignificant amount of current.) Show that this result justifies calling this circuit a high-pass filter.

Picture the Problem The phasor diagram for the *RC* high-pass filter is shown to the right. $\vec{V}_{\rm app}$ and $\vec{V}_R$ are the phasors for $V_{\rm in}$ and $V_{\rm out}$, respectively. Note that $\tan\delta = -X_C/R$. That δ is negative follows from the fact that $\vec{V}_{\rm app}$ lags $\vec{V}_R$ by $|\delta|$. The projection of $\vec{V}_{\rm app}$ onto the horizontal axis is $V_{\rm app} = V_{\rm in}$, and the projection of $\vec{V}_R$ onto the horizontal axis is $V_R = V_{\rm out}$.



Express $V_{\rm app}$:

$$V_{\rm app} = V_{\rm app,peak}\cos\omega t$$

where $V_{\rm app,peak} = V_{\rm peak} = I_{\rm peak}Z$

and $Z^2 = R^2 + X_C^2$ (1)

Because $\delta < 0$:

$$\omega t + |\delta| = \omega t - \delta$$

V_R is given by:

$$V_R = V_{R,\,\text{peak}} \cos(\omega t - \delta)$$
where $V_{R,\,\text{peak}} = V_{\text{H}} = I_{\text{peak}} R$

Solving equation (1) for Z and substituting for X_C yields:

$$Z = \sqrt{R^2 + \left(\frac{1}{\omega C}\right)^2} \qquad (2)$$

Because $V_{\text{out}} = V_R$:

$$\begin{aligned} V_{\text{out}} &= V_{R,\,\text{peak}} \cos(\omega t - \delta) \\ &= I_{\text{in peak}} R \cos(\omega t - \delta) \\ &= \frac{V_{\text{in peak}}}{Z} R \cos(\omega t - \delta) \end{aligned}$$

Using equation (2) to substitute for Z yields:

$$V_{\text{out}} = \frac{V_{\text{in peak}}}{\sqrt{R^2 + \left(\frac{1}{\omega C}\right)^2}} R \cos(\omega t - \delta)$$

Simplify further to obtain:

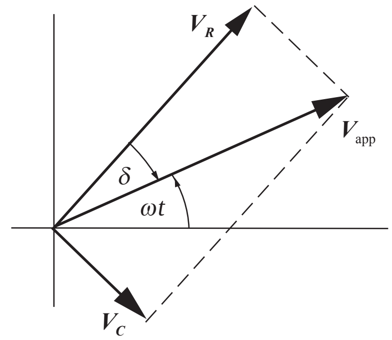
$$V_{\text{out}} = \frac{V_{\text{in peak}}}{\sqrt{1 + (\omega RC)^{-2}}} \cos(\omega t - \delta)$$
or
$$V_{\text{out}} = \boxed{V_{\text{H}} \cos(\omega t - \delta)}$$
where
$$V_{\text{H}} = \boxed{\frac{V_{\text{in peak}}}{\sqrt{1 + (\omega RC)^{-2}}}}$$

As $\omega \to \infty$:

$$V_{\text{H}} \to \frac{V_{\text{in peak}}}{\sqrt{1 + (0)^2}} = V_{\text{in peak}}$$ showing that the result is consistent with the high-pass name for this circuit.

45 •• (*a*) Find an expression for the phase constant δ in Problem 44 in terms of ω, R and C. (*b*) What is the value of δ in the limit that $\omega \to 0$? (*c*) What is the value of δ in the limit that $\omega \to \infty$? (*d*) Explain your answers to Parts (*b*) and (*c*).

Picture the Problem The phasor diagram for the *RC* high-pass filter is shown below. $\vec{V}_{\text{app}}$ and $\vec{V}_R$ are the phasors for V_{in} and V_{out}, respectively. The projection of $\vec{V}_{\text{app}}$ onto the horizontal axis is $V_{\text{app}} = V_{\text{in}}$, and the projection of $\vec{V}_{\text{R}}$ onto the horizontal axis is $V_R = V_{\text{out}}$.



(*a*) Because $\vec{V}_{\text{app}}$ lags $\vec{V}_{\text{R}}$ by $|\delta|$.

$$\tan\delta = -\frac{V_C}{V_R} = -\frac{IX_C}{IR} = -\frac{X_C}{R}$$

Use the definition of X_C to obtain:

$$\tan\delta = -\frac{\frac{1}{\omega C}}{R} = -\frac{1}{\omega RC}$$

Solving for δ yields:

$$\delta = \boxed{\tan^{-1}\left[-\frac{1}{\omega RC}\right]}$$

(*b*) As $\omega \to 0$:

$$\delta \to \boxed{-90°}$$

(*c*) As $\omega \to \infty$:

$$\delta \to \boxed{0}$$

(*d*) For very low driving frequencies, $X_C >> R$ and so $\vec{V}_C$ effectively lags $\vec{V}_{\text{in}}$ by 90°. For very high driving frequencies, $X_C << R$ and so $\vec{V}_R$ is effectively in phase with $\vec{V}_{\text{in}}$.

46 •• Assume that in Problem 44, $R = 20$ kΩ and $C = 15$ nF. (*a*) At what frequency is $V_{\text{H}} = \frac{1}{\sqrt{2}}V_{\text{in peak}}$? This particular frequency is known as the 3 dB frequency, or $f_{3\text{dB}}$ for the circuit. (*b*) Using a **spreadsheet** program, make a graph of $\log_{10}(V_{\text{H}})$ versus $\log_{10}(f)$, where f is the frequency. Make sure that the scale extends from at least 10% of the 3-dB frequency to ten times the 3-dB frequency. (*c*) Make a graph of δ versus $\log_{10}(f)$ for the same range of frequencies as in Part (*b*). What is the value of the phase constant when the frequency is equal to the 3-dB frequency?

Picture the Problem We can use the results obtained in Problems 44 and 45 to find $f_{3\text{ dB}}$ and to plot graphs of $\log(V_{\text{out}})$ versus $\log(f)$ and δ versus $\log(f)$.

(*a*) Use the result of Problem 44 to express the ratio $V_{out}/V_{in\ peak}$:

$$\frac{V_{out}}{V_{in\ peak}}=\frac{\dfrac{V_{in\ peak}}{\sqrt{1+(\omega RC)^{-2}}}}{V_{in\ peak}}=\frac{1}{\sqrt{1+(\omega RC)^{-2}}}$$

When $V_{out}=V_{in\ peak}/\sqrt{2}$:

$$\frac{1}{\sqrt{1+(\omega RC)^{-2}}}=\frac{1}{\sqrt{2}}$$

Square both sides of the equation and solve for ωRC to obtain:

$$\omega RC=1\Rightarrow\ \omega=\frac{1}{RC}\Rightarrow\ f_{3\,\mathrm{dB}}=\frac{1}{2\pi RC}$$

Substitute numerical values and evaluate $f_{3\,\mathrm{dB}}$:

$$f_{3\,\mathrm{dB}}=\frac{1}{2\pi(20\,\mathrm{k\Omega})(15\,\mathrm{nF})}=\boxed{0.53\,\mathrm{kHz}}$$

(*b*) From Problem 44 we have:

$$V_{out}=\frac{V_{in\ peak}}{\sqrt{1+(\omega RC)^{-2}}}$$

In Problem 45 it was shown that:

$$\delta=\tan^{-1}\left[-\frac{1}{\omega RC}\right]$$

Rewrite these expressions in terms of $f_{3\,\mathrm{dB}}$ to obtain:

$$V_{out}=\frac{V_{in\ peak}}{\sqrt{1+\left(\dfrac{1}{2\pi fRC}\right)^2}}=\frac{V_{peak}}{\sqrt{1+\left(\dfrac{f_{3\,\mathrm{dB}}}{f}\right)^2}}$$

and

$$\delta=\tan^{-1}\left[-\frac{1}{2\pi fRC}\right]=\tan^{-1}\left[-\frac{f_{3\,\mathrm{dB}}}{f}\right]$$

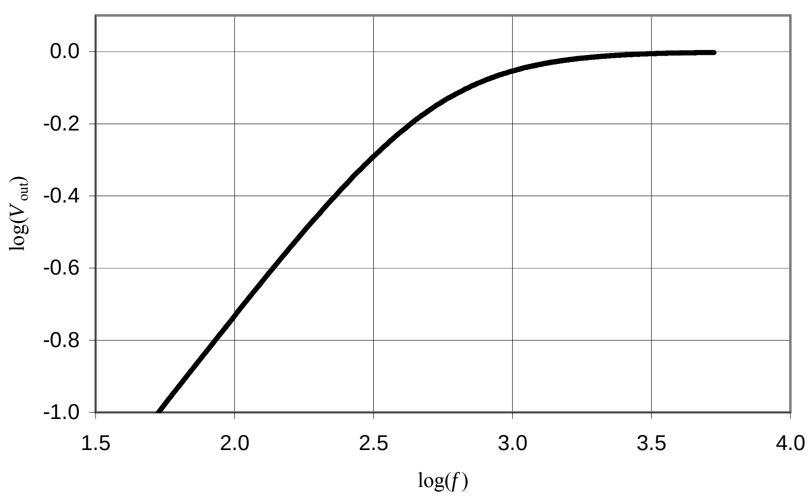
A spreadsheet program to generate the data for a graph of V_{out} versus f and δ versus f is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	2.00E+03	R
B2	1.50E−08	C
B3	1	$V_{in\ peak}$
B4	531	$f_{3\,\mathrm{dB}}$
A8	53	$0.1f_{3\,\mathrm{dB}}$
C8	$B$3/SQRT(1+(1($B$4/A8))^2)	$\dfrac{V_{in\ peak}}{\sqrt{1+\left(\dfrac{f_{3\,\mathrm{dB}}}{f}\right)^2}}$

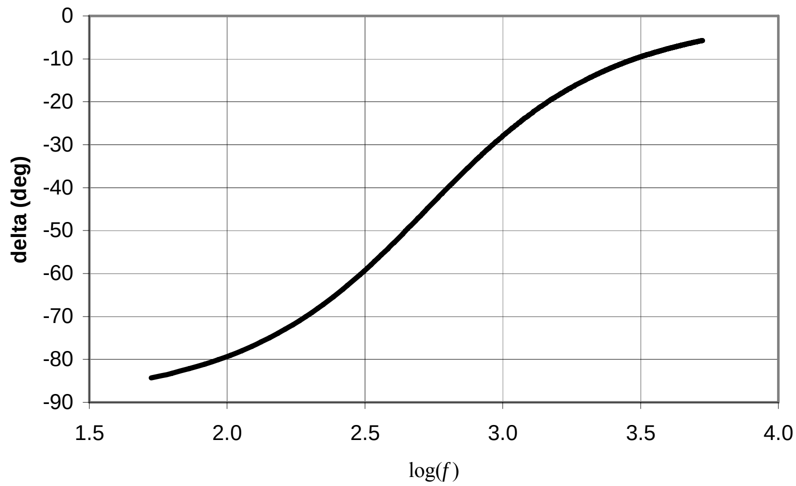
D8	LOG(C8)	$\log(V_{out})$
E8	ATAN(−$B$4/A8)	$\tan^{-1}\left[-\frac{f_{3\,dB}}{f}\right]$
F8	E8*180/PI()	δ in degrees

	A	B	C	D	E	F
1	R=	2.00E+04	ohms			
2	C=	1.50E−08	F			
3	$V_{in\ peak}$=	1	V			
4	$f_{3\ dB}$=	531	Hz			
5						
6						
7	f	log(f)	V_{out}	log(V_{out})	delta(rad)	delta(deg)
8	53	1.72	0.099	−1.003	−1.471	−84.3
9	63	1.80	0.118	−0.928	−1.453	−83.2
10	73	1.86	0.136	−0.865	−1.434	−82.2
11	83	1.92	0.155	−0.811	−1.416	−81.1
55	523	2.72	0.702	−0.154	−0.793	−45.4
56	533	2.73	0.709	−0.150	−0.783	−44.9
57	543	2.73	0.715	−0.146	−0.774	−44.3
531	5283	3.72	0.995	−0.002	−0.100	−5.7
532	5293	3.72	0.995	−0.002	−0.100	−5.7
533	5303	3.72	0.995	−0.002	−0.100	−5.7
534	5313	3.73	0.995	−0.002	−0.100	−5.7

The following graph of $\log(V_{out})$ versus $\log(f)$ was plotted for $V_{in\ peak} = 1$ V.



A graph of δ (in degrees) as a function of log(f) follows.



Referring to the spreadsheet program, we see that when $f = f_{3\text{ dB}}$, $\delta \approx \boxed{-44.9°.}$ This result is in good agreement with its calculated value of $-45.0°$.

47 •• [SSM] A slowly varying voltage signal $V(t)$ is applied to the input of the high-pass filter of Problem 44. Slowly varying means that during one time constant (equal to RC) there is no significant change in the voltage signal. Show that under these conditions the output voltage is proportional to the time derivative of $V(t)$. This situation is known as a *differentiation circuit.*

Picture the Problem We can use Kirchhoff's loop rule to obtain a differential equation relating the input, capacitor, and resistor voltages. Because the voltage drop across the resistor is small compared to the voltage drop across the capacitor, we can express the voltage drop across the capacitor in terms of the input voltage.

Apply Kirchhoff's loop rule to the input side of the filter to obtain:

$$V(t) - V_C - IR = 0$$

where V_C is the potential difference across the capacitor.

Substitute for $V(t)$ and I to obtain:

$$V_{\text{in peak}} \cos \omega t - V_c - R\frac{dQ}{dt} = 0$$

Because $Q = CV_C$:

$$\frac{dQ}{dt} = \frac{d}{dt}\left[CV_C\right] = C\frac{dV_C}{dt}$$

Substitute for dQ/dt to obtain:

$$V_{\text{peak}}\cos\omega t - V_C - RC\frac{dV_C}{dt} = 0$$

the differential equation describing the potential difference across the capacitor.

Because there is no significant change in the voltage signal during one time constant:

$$\frac{dV_C}{dt} = 0 \Rightarrow RC\frac{dV_C}{dt} = 0$$

Substituting for $RC\dfrac{dV_C}{dt}$ yields:

$$V_{\text{in peak}}\cos\omega t - V_C = 0$$

and

$$V_C = V_{\text{in peak}}\cos\omega t$$

Consequently, the potential difference across the resistor is given by:

$$V_R = RC\frac{dV_C}{dt} = \boxed{RC\frac{d}{dt}\left[V_{\text{in peak}}\cos\omega t\right]}$$

48 •• We can describe the output from the high-pass filter from Problem 44 using a decibel scale: $\beta = (20\text{ dB})\log_{10}\left(V_{\text{H}}/V_{\text{in peak}}\right)$, where β is the output in decibels. Show that for $V_{\text{H}} = \frac{1}{\sqrt{2}}V_{\text{in peak}}$, $\beta = -3.0$ dB. The frequency at which $V_{\text{H}} = \frac{1}{\sqrt{2}}V_{\text{in peak}}$ is known as $f_{3\text{dB}}$ (the 3-dB frequency). Show that for $f << f_{3\text{dB}}$, the output β drops by 6 dB if the frequency f is halved.

Picture the Problem We can use the expression for V_{H} from Problem 44 and the definition of β given in the problem to show that every time the frequency is halved, the output drops by 6 dB.

We're given that:

$$\beta = (20\text{ dB})\log_{10}\left(\frac{V_{\text{H}}}{V_{\text{in peak}}}\right)$$

For $V_{\text{H}} = \frac{1}{\sqrt{2}}V_{\text{in peak}}$:

$$\beta = (20\text{ dB})\log_{10}\left(\frac{\frac{1}{\sqrt{2}}V_{\text{in peak}}}{V_{\text{in peak}}}\right)$$

$$= (20\text{ dB})\log_{10}\left(\frac{1}{\sqrt{2}}\right) = \boxed{-3.0\text{ dB}}$$

From Problem 44:

$$V_H = \frac{V_{\text{in peak}}}{\sqrt{1+(\omega RC)^{-2}}}$$

or

$$\frac{V_H}{V_{\text{in peak}}} = \frac{1}{\sqrt{1+(\omega RC)^{-2}}}$$

Express this ratio in terms of f and $f_{3\text{ dB}}$ and simplify to obtain:

$$\frac{V_H}{V_{\text{peak}}} = \frac{1}{\sqrt{1+\left(\frac{f_{3\text{ dB}}}{f}\right)^2}} = \frac{f}{\sqrt{f_{3\text{ dB}}^2\left(1+\frac{f^2}{f_{3\text{ dB}}^2}\right)}}$$

For $f << f_{3\text{dB}}$:

$$\frac{V_H}{V_{\text{peak}}} \approx \frac{f}{\sqrt{f_{3\text{ dB}}^2\left(1+\frac{f^2}{f_{3\text{ dB}}^2}\right)}} = \frac{f}{f_{3\text{ dB}}}$$

From the definition of β we have:

$$\beta = 20\log_{10}\left(\frac{V_H}{V_{\text{peak}}}\right)$$

Substitute for V_H/V_{peak} to obtain:

$$\beta = 20\log_{10}\left(\frac{f}{f_{3\text{ dB}}}\right)$$

Doubling the frequency yields:

$$\beta' = 20\log_{10}\left(\frac{\frac{1}{2}f}{f_{3\text{ dB}}}\right)$$

The change in decibel level is:

$$\begin{aligned}\Delta\beta &= \beta' - \beta \\ &= 20\log_{10}\left(\frac{\frac{1}{2}f}{f_{3\text{ dB}}}\right) - 20\log_{10}\left(\frac{f}{f_{3\text{ dB}}}\right) \\ &= 20\log_{10}\left(\tfrac{1}{2}\right) \approx \boxed{-6\,\text{dB}}\end{aligned}$$

49 •• [SSM] Show that the average power dissipated in the resistor of the high-pass filter of Problem 44 is given by $P_{\text{ave}} = \dfrac{V_{\text{in peak}}^2}{2R\left[1+(\omega RC)^{-2}\right]}$.

Picture the Problem We can express the instantaneous power dissipated in the resistor and then use the fact that the average value of the square of the cosine function over one cycle is ½ to establish the given result.

The instantaneous power $P(t)$ dissipated in the resistor is:

$$P(t)=\frac{V_{\text{out}}^2}{R}$$

The output voltage V_{out} is:

$$V_{\text{out}}=V_{\text{H}}\cos(\omega t-\delta)$$

From Problem 44:

$$V_{\text{H}}=\frac{V_{\text{in peak}}}{\sqrt{1+(\omega RC)^{-2}}}$$

Substitute in the expression for $P(t)$ to obtain:

$$P(t)=\frac{V_{\text{H}}^2}{R}\cos^2(\omega t-\delta)$$
$$=\frac{V_{\text{in peak}}^2}{R\left[1+(\omega RC)^{-2}\right]}\cos^2(\omega t-\delta)$$

Because the average value of the square of the cosine function over one cycle is ½:

$$P_{\text{ave}}=\boxed{\frac{V_{\text{in peak}}^2}{2R\left[1+(\omega RC)^{-2}\right]}}$$

50 •• One application of the high-pass filter of Problem 44 is a noise filter for electronic circuits (a filter that blocks out low-frequency noise). Using a resistance value of 20 kΩ, find a value for the capacitance for the high-pass filter that attenuates a 60-Hz input voltage signal by a factor of 10. That is, so $V_{\text{H}}=\frac{1}{10}V_{\text{in peak}}$.

Picture the Problem We can solve the expression for V_{H} from Problem 44 for the required capacitance of the capacitor.

From Problem 44:

$$V_{\text{H}}=\frac{V_{\text{in peak}}}{\sqrt{1+(\omega RC)^{-2}}}$$

We require that:

$$\frac{V_{\text{H}}}{V_{\text{in peak}}}=\frac{1}{\sqrt{1+(\omega RC)^{-2}}}=\frac{1}{10}$$

or

$$\sqrt{1+(\omega RC)^{-2}}=10$$

Solving for C yields:

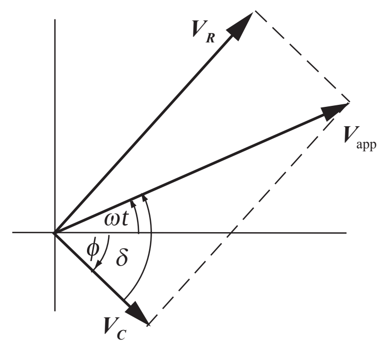
$$C=\frac{1}{\sqrt{99}\,\omega R}=\frac{1}{2\pi\sqrt{99}\,Rf}$$

Substitute numerical values and evaluate C:

$$C=\frac{1}{2\pi\sqrt{99}(20\,\text{k}\Omega)(60\,\text{Hz})}=\boxed{13\,\text{nF}}$$

51 •• [SSM] The circuit shown in Figure 29-36 is an example of a low-pass filter. (Assume that the output is connected to a load that draws only an insignificant amount of current.) (*a*) If the input voltage is given by $V_{in} = V_{in\,peak}\cos\omega t$, show that the output voltage is $V_{out} = V_L\cos(\omega t - \delta)$ where $V_L = V_{in\,peak}\Big/\sqrt{1+(\omega RC)^2}$. (*b*) Discuss the trend of the output voltage in the limiting cases $\omega \to 0$ and $\omega \to \infty$.

Picture the Problem In the phasor diagram for the *RC* low-pass filter, $\vec{V}_{app}$ and $\vec{V}_C$ are the phasors for V_{in} and V_{out}, respectively. The projection of $\vec{V}_{app}$ onto the horizontal axis is $V_{app} = V_{in}$, the projection of $\vec{V}_C$ onto the horizontal axis is $V_C = V_{out}$, $V_{peak} = \left|\vec{V}_{app}\right|$, and ϕ is the angle between $\vec{V}_C$ and the horizontal axis.



(*a*) Express V_{app}:

$$V_{app} = V_{in\,peak}\cos\omega t$$

where $V_{in\,peak} = I_{peak}Z$

and $Z^2 = R^2 + X_C^2$ (1)

$V_{out} = V_C$ is given by:

$$V_{out} = V_{C,peak}\cos\phi = I_{peak}X_C\cos\phi$$

If we define δ as shown in the phasor diagram, then:

$$V_{out} = I_{peak}X_C\cos(\omega t - \delta) = \frac{V_{in\,peak}}{Z}X_C\cos(\omega t - \delta)$$

Solving equation (1) for *Z* and substituting for X_C yields:

$$Z = \sqrt{R^2 + \left(\frac{1}{\omega C}\right)^2} \qquad (2)$$

Using equation (2) to substitute for *Z* and substituting for X_C yields:

$$V_{out} = \frac{V_{in\,peak}}{\sqrt{R^2 + \left(\frac{1}{\omega C}\right)^2}}\frac{1}{\omega C}\cos(\omega t - \delta)$$

Simplify further to obtain:

$$V_{out} = \frac{V_{\text{in peak}}}{\sqrt{1+(\omega RC)^2}}\cos(\omega t - \delta)$$

or

$$V_{out} = \boxed{V_L \cos(\omega t - \delta)}$$

where

$$V_L = \boxed{\frac{V_{\text{in peak}}}{\sqrt{1+(\omega RC)^2}}}$$

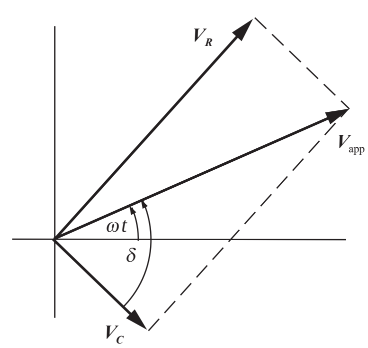
(*b*) Note that, as $\omega \to 0$, $V_L \to V_{peak}$. This makes sense physically in that, for low frequencies, X_C is large and, therefore, a larger peak input voltage will appear across it than appears across it for high frequencies.

Note further that, as $\omega \to \infty$, $V_L \to 0$. This makes sense physically in that, for high frequencies, X_C is small and, therefore, a smaller peak voltage will appear across it than appears across it for low frequencies.

Remarks: In Figures 29-19 and 29-20, δ is defined as the phase of the voltage drop across the combination relative to the voltage drop across the resistor.

52 •• (*a*) Find an expression for the phase angle δ for the low-pass filter of Problem 51 in terms of ω, R and C. (*b*) Find the value of δ in the limit that $\omega \to 0$ and in the limit that $\omega \to \infty$. Explain your answer.

Picture the Problem The phasor diagram for the *RC* low-pass filter is shown to the right. $\vec{V}_{app}$ and $\vec{V}_C$ are the phasors for V_{in} and V_{out}, respectively. The projection of $\vec{V}_{app}$ onto the horizontal axis is $V_{app} = V_{in}$ and the projection of $\vec{V}_C$ onto the horizontal axis is $V_C = V_{out}$. $V_{peak} = \left|\vec{V}_{app}\right|$.



(*a*) From the phasor diagram we have:

$$\tan\delta = \frac{V_R}{V_C} = \frac{I_{peak}R}{I_{peak}X_C} = \frac{R}{X_C}$$

Use the definition of X_C to obtain:

$$\tan\delta = \frac{R}{\frac{1}{\omega C}} = \omega RC$$

Solving for δ yields:

$$\delta = \boxed{\tan^{-1}(\omega RC)}$$

(b) As $\omega \to 0$, $\delta \to \boxed{0°}$. This behavior makes sense physically in that, at low frequencies, X_C is very large compared to R and, as a consequence, V_C is in phase with V_{in} .

As $\omega \to \infty$, $\delta \to \boxed{90°}$. This behavior makes sense physically in that, at high frequencies, X_C is very small compared to R and, as a consequence, V_C is out of phase with V_{in} .

Remarks: See the spreadsheet solution in the following problem for additional evidence that our answer for Part (*b*) is correct.

53 •• Using a **spreadsheet** program, make a graph of V_L versus input frequency f and a graph of phase angle δ versus input frequency for the low-pass filter of Problems 51 and 52. Use a resistance value of 10 kΩ and a capacitance value of 5.0 nF.

Picture the Problem We can use the expressions for V_L and δ derived in Problems 51 and 52 to plot the graphs of V_L versus f and δ versus f for the low-pass filter of Problem 51. We'll simplify the spreadsheet program by expressing both V_L and δ as functions of $f_{3\text{ dB}}$.

From Problems 51 and 52 we have:

$$V_L = \frac{V_{\text{in peak}}}{\sqrt{1+(\omega RC)^2}}$$

and

$$\delta = \tan^{-1}(\omega RC)$$

Rewrite each of these expressions in terms of f to obtain:

$$V_L = \frac{V_{\text{in peak}}}{\sqrt{1+(2\pi fRC)^2}}$$

and

$$\delta = \tan^{-1}(2\pi fRC)$$

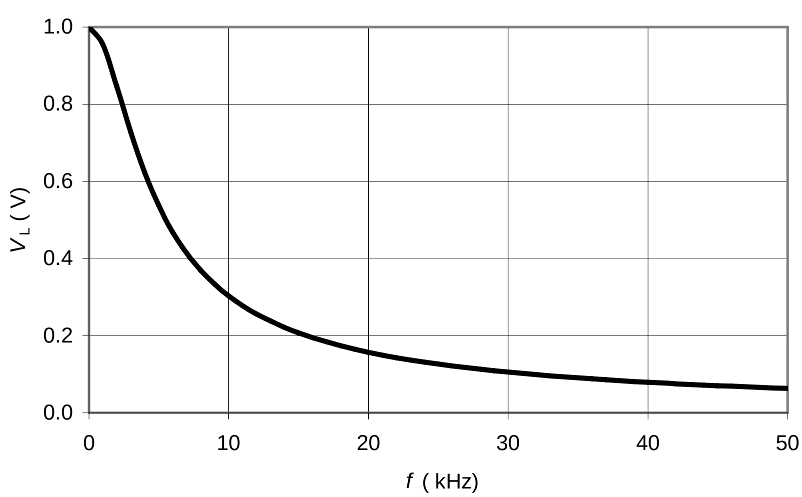
A spreadsheet program to generate the data for graphs of V_L versus f and δ versus f for the low-pass filter is shown below. Note that $V_{\text{in peak}}$ has been arbitrarily set equal to 1 V. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B1	2.00E+03	R
B2	5.00E−09	C

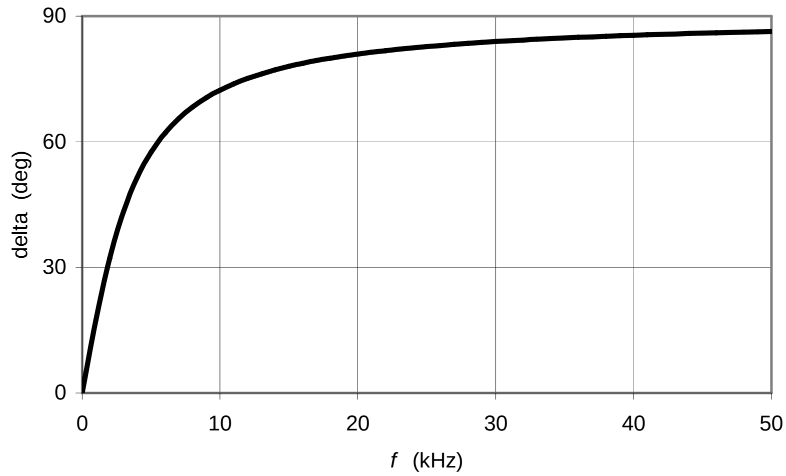
B3	1	$V_{\text{in peak}}$
B8	$B$3/SQRT(1+((2*PI()*A8*1000*$B$1*$B$2)^2))	$\dfrac{V_{\text{in peak}}}{\sqrt{1+(2\pi fRC)^2}}$
C8	ATAN(2*PI()*A8*1000*$B$1*$B$2)	$\tan^{-1}(2\pi fRC)$
D8	C8*180/PI()	δ in degrees

	A	B	C	D
1	R=	1.00E+04	ohms	
2	C=	5.00E−09	F	
3	$V_{\text{in peak}}$=	1	V	
4				
5				
6	f(kHz)	V_{out}	δ(rad)	δ(deg)
7	0	1.000	0.000	0.0
8	1	0.954	0.304	17.4
9	2	0.847	0.561	32.1
10	3	0.728	0.756	43.3
54	47	0.068	1.503	86.1
55	48	0.066	1.505	86.2
56	49	0.065	1.506	86.3
57	50	0.064	1.507	86.4

A graph of V_L as a function of f follows:



A graph of δ as a function of f follows:



54 ••• A rapidly varying voltage signal $V(t)$ is applied to the input of the low-pass filter of Problem 51. Rapidly varying means that during one time constant (equal to RC) there are significant changes in the voltage signal. Show that under these conditions the output voltage is proportional to the integral of $V(t)$ with respect to time. This situation is known as an *integration circuit*.

Picture the Problem We can use Kirchhoff's loop rule to obtain a differential equation relating the input, capacitor, and resistor voltages. We'll then assume a solution to this equation that is a linear combination of sine and cosine terms with coefficients that we can find by substitution in the differential equation. The solution to these simultaneous equations will yield the amplitude of the output voltage.

Apply Kirchhoff's loop rule to the input side of the filter to obtain:

$$V(t) - IR - V_C = 0$$

where V_C is the potential difference across the capacitor.

Substitute for $V(t)$ and I to obtain:

$$V_{\text{in peak}} \cos\omega t - R\frac{dQ}{dt} - V_C = 0$$

Because $Q = CV_C$:

$$\frac{dQ}{dt} = \frac{d}{dt}[CV_C] = C\frac{dV_C}{dt}$$

Substitute for dQ/dt to obtain:

$$V_{\text{in peak}} \cos\omega t - RC\frac{dV_C}{dt} - V_C = 0$$

the differential equation describing the potential difference across the capacitor.

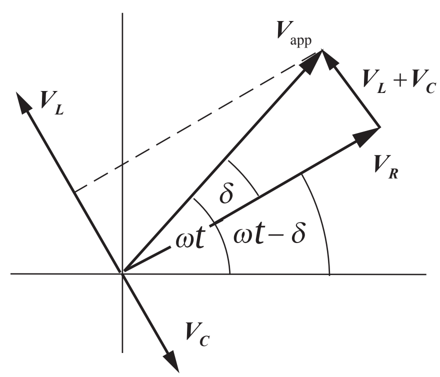
V_C is given by: $V_C = IX_c = \dfrac{I}{\omega C}$

The fact that $V(t)$ varies rapidly means that $\omega >> 1$ and so: $V_C \approx 0$
and
$V_{\text{peak}} \cos\omega t - RC\dfrac{dV_C}{dt} = 0$

Separating the variables in this differential equation and solving for V_C yields: $V_C = \boxed{\dfrac{1}{RC}\int V_{\text{peak}} \cos\omega t dt}$

55 ••• **[SSM]** The circuit shown in Figure 29-37 is a *trap filter*. (Assume that the output is connected to a load that draws only an insignificant amount of current.) (*a*) Show that the *trap filter* acts to reject signals in a band of frequencies centered at $\omega = 1/\sqrt{LC}$. (*b*) How does the width of the frequency band rejected depend on the resistance *R*?

Picture the Problem The phasor diagram for the *trap* filter is shown below. $\vec{V}_{\text{app}}$ and $\vec{V}_L + \vec{V}_C$ are the phasors for V_{in} and V_{out}, respectively. The projection of $\vec{V}_{\text{app}}$ onto the horizontal axis is $V_{\text{app}} = V_{\text{in}}$, and the projection of $\vec{V}_L + \vec{V}_C$ onto the horizontal axis is $V_L + V_C = V_{\text{out}}$. Requiring that the impedance of the trap be zero will yield the frequency at which the circuit rejects signals. Defining the bandwidth as $\Delta\omega = \left|\omega - \omega_{\text{trap}}\right|$ and requiring that $\left|Z_{\text{trap}}\right| = R$ will yield an expression for the bandwidth and reveal its dependence on *R*.



(*a*) Express V_{app}: $V_{\text{app}} = V_{\text{app, peak}} \cos\omega t$
where $V_{\text{app, peak}} = V_{\text{peak}} = I_{\text{peak}} Z$
and $Z^2 = R^2 + \left(X_L - X_C\right)^2$ (1)

V_{out} is given by:

$$V_{\text{out}} = V_{\text{out, peak}} \cos(\omega t - \delta)$$
where $V_{\text{out, peak}} = I_{\text{peak}} Z_{\text{trap}}$
and $Z_{\text{trap}} = X_L - X_C$

Solving equation (1) for Z yields:

$$Z = \sqrt{R^2 + (X_L - X_C)^2} \qquad (2)$$

Because $V_{\text{out}} = V_{\text{L}} + V_C$:

$$\begin{aligned} V_{\text{out}} &= V_{\text{out, peak}} \cos(\omega t - \delta) \\ &= I_{\text{peak}} Z_{\text{trap}} \cos(\omega t - \delta) \\ &= \frac{V_{\text{peak}}}{Z} Z_{\text{trap}} \cos(\omega t - \delta) \end{aligned}$$

Using equation (2) to substitute for Z yields:

$$V_{\text{out}} = \frac{V_{\text{peak}}}{\sqrt{R^2 + Z_{\text{trap}}^2}} Z_{\text{trap}} \cos(\omega t - \delta)$$

Noting that $V_{\text{out}} = 0$ provided $Z_{\text{trap}} = 0$, set $Z_{\text{trap}} = 0$ to obtain:

$$Z_{\text{trap}} = X_L - X_C = 0$$

Substituting for X_L and X_C yields:

$$\omega L - \frac{1}{\omega C} = 0 \Rightarrow \omega = \boxed{\frac{1}{\sqrt{LC}}}$$

(*b*) Let the bandwidth $\Delta\omega$ be:

$$\Delta\omega = \left|\omega - \omega_{\text{trap}}\right| \qquad (3)$$

Let the frequency bandwidth be defined by the frequency at which $\left|Z_{\text{trap}}\right| = R$. Then:

$$\omega L - \frac{1}{\omega C} = R \Rightarrow \omega^2 LC - 1 = \omega RC$$

Because $\omega_{\text{trap}} = \dfrac{1}{\sqrt{LC}}$:

$$\left(\frac{\omega}{\omega_{\text{trap}}}\right)^2 - 1 = \omega RC$$

For $\omega \approx \omega_{\text{trap}}$:

$$\left(\frac{\omega^2 - \omega_{\text{trap}}^2}{\omega_{\text{trap}}}\right) \approx \omega_{\text{trap}} RC$$

Solve for $\omega^2 - \omega_{\text{trap}}^2$:

$$\omega^2 - \omega_{\text{trap}}^2 = (\omega - \omega_{\text{trap}})(\omega + \omega_{\text{trap}})$$

Because $\omega \approx \omega_{\text{trap}}$, $\omega + \omega_{\text{trap}} \approx 2\omega_{\text{trap}}$:

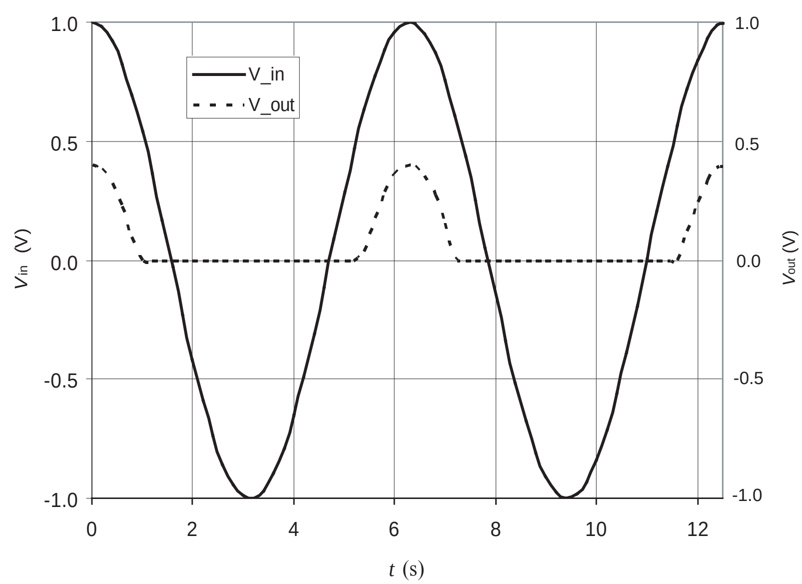
$$\omega^2 - \omega_{\text{trap}}^2 \approx 2\omega_{\text{trap}}(\omega - \omega_{\text{trap}})$$

Substitute in equation (3) to obtain:

$$\Delta\omega = \left|\omega - \omega_{\text{trap}}\right| = \frac{RC\omega_{\text{trap}}^2}{2} = \boxed{\frac{R}{2L}}$$

56 ••• A half-wave rectifier for transforming an ac voltage into a dc voltage is shown in Figure 29-38. The diode in the figure can be thought of as a one-way valve for current. It allows current to pass in the forward direction (the direction of the arrowhead) only when V_{in} is at a higher electric potential than V_{out} by 0.60 V (that is, whenever $V_{\text{in}} - V_{\text{out}} \geq +0.60\text{ V}$). The resistance of the diode is effectively infinite when $V_{\text{in}} - V_{\text{out}}$ is less than +0.60 V. Plot two cycles of both input and output voltages as a function of time, on the same graph, assuming the input voltage is given by $V_{\text{in}} = V_{\text{in peak}} \cos \omega t$.

Picture the Problem For voltages greater than 0.60 V, the output voltage will mirror the input voltage minus a 0.60 V drop. But when the voltage swings below 0.60 V, the output voltage will be 0. A spreadsheet program was used to plot the following graph. The angular frequency and the peak voltage were both arbitrarily set equal to one.



57 ••• The output of the rectifier of Problem 56, can be further filtered by putting its output through a low-pass filter as shown in Figure 29-39*a*. The resulting output is a dc voltage with a small ac component (ripple) shown in Figure 29-39*b*. If the input frequency is 60 Hz and the load resistance is 1.00 kΩ, find the value for the capacitance so that the output voltage varies by less than 50 percent of the mean value over one cycle.

Picture the Problem We can use the decay of the potential difference across the capacitor to relate the time constant for the *RC* circuit to the frequency of the input signal. Expanding the exponential factor in the expression for V_C will allow

us to find the approximate value for C that will limit the variation in the output voltage by less than 50 percent (or any other percentage).

The voltage across the capacitor is given by:

$$V_C = V_{\text{in}} e^{-t/RC}$$

Expand the exponential factor to obtain:

$$e^{-t/RC} \approx 1 - \frac{1}{RC}t$$

For a decay of less than 50 percent:

$$1 - \frac{1}{RC}t \leq 0.5 \Rightarrow C \leq \frac{2}{R}t$$

Because the voltage goes positive every cycle, $t = 1/60$ s and:

$$C \leq \frac{2}{1.00\,\text{k}\Omega}\left(\frac{1}{60}\text{s}\right) = \boxed{33\,\mu\text{F}}$$

Driven *LC* Circuits

58 •• The generator voltage in Figure 29-40, is given by $\mathcal{E} = (100\text{ V})\cos(2\pi ft)$. (*a*) For each branch, what is the peak current and what is the phase of the current relative to the phase of the generator voltage? (*b*) At the resonance frequency there is no current in the generator. What is the angular frequency at resonance? (*c*) At the resonance frequency, find the current in the inductor and what is the current in the capacitor. Express your results as functions of time. (*d*) Draw a phasor diagram showing the phasors for the applied voltage, the generator current, the capacitor current, and the inductor current for the case where frequency is higher than the resonance frequency.

Picture the Problem We know that the current leads the voltage across and capacitor and lags the voltage across an inductor. We can use $I_{L,\,\text{peak}} = \mathcal{E}_{\text{peak}}/X_L$ and $I_{C,\,\text{peak}} = \mathcal{E}_{\text{peak}}/X_C$ to find the amplitudes of these currents. The current in the generator will vanish under resonance conditions, i.e., when $|I_L| = |I_C|$. To find the currents in the inductor and capacitor at resonance, we can use the common potential difference across them and their reactances together with our knowledge of the phase relationships mentioned above.

(*a*) Express the amplitudes of the currents through the inductor and the capacitor:

$$I_{L,\,\text{peak}} = \frac{\mathcal{E}_{\text{peak}}}{X_L} = \frac{\mathcal{E}_{\text{peak}}}{2\pi fL}$$

and

$$I_{C,\,\text{peak}} = \frac{\mathcal{E}_{\text{peak}}}{X_C} = \frac{\mathcal{E}_{\text{peak}}}{\frac{1}{2\pi fC}} = 2\pi fC\mathcal{E}_{\text{peak}}$$

Substitute numerical values to obtain:

$$I_{L,\,\text{peak}} = \frac{100\,\text{V}}{(4.00\,\text{H})2\pi f} = \boxed{\frac{25.0\,\text{V/H}}{2\pi f},\ \text{lagging } \mathcal{E} \text{ by } 90°}$$

and

$$I_{C,\,\text{peak}} = (25.0\,\mu\text{F})(100\,\text{V})\omega = \boxed{(2.50\,\text{mV}\cdot\text{F})2\pi f\text{, leading } \mathcal{E} \text{ by } 90°}$$

(*b*) Express the condition that $I = 0$:

$$|I_L| = |I_C| \text{ or } \frac{\mathcal{E}}{\omega L} = \frac{\mathcal{E}}{\frac{1}{\omega C}} = \omega C\mathcal{E}$$

Solve for ω to obtain:

$$\omega = \frac{1}{\sqrt{LC}}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{1}{\sqrt{(4.00\,\text{H})(25.0\,\mu\text{F})}} = \boxed{100\,\text{rad/s}}$$

(*c*) Express the current in the inductor at $\omega = \omega_0$:

$$I_L = \left(\frac{25.0\,\text{V/H}}{100\,\text{s}^{-1}}\right)\cos\left(\omega t - \frac{\pi}{2}\right)$$

$$= \boxed{(250\,\text{mA})\cos\left(\omega t - \frac{\pi}{2}\right)}$$

where $\omega = 100$ rad/s.

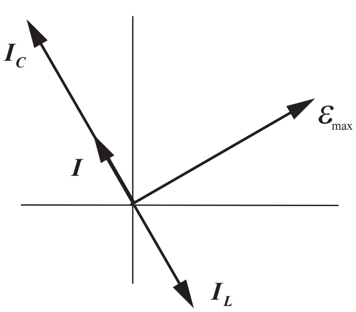
Express the current in the capacitor at $\omega = \omega_0$:

$$I_C = (2.50\,\text{mV}\cdot\text{F})(100\,\text{s}^{-1})\cos\left(\omega t + \frac{\pi}{2}\right)$$

$$= \boxed{-(250\,\text{mA})\cos\left(\omega t + \frac{\pi}{2}\right)}$$

where $\omega = 100$ rad/s.

(*d*) The phasor diagram for the case where the inductive reactance is larger than the capacitive reactance is shown to the right.



59 •• A circuit consist of an ideal ac generator, a capacitor and an ideal inductor, all connected in series. The charge on the capacitor is given by $Q = (15\ \mu\text{C})\cos(\omega t + \frac{\pi}{4})$, where $\omega = 1250$ rad/s. (*a*) Find the current in the circuit as a function of time. (*b*) Find the capacitance if the inductance is 28 mH. (*c*) Write expressions for the electrical energy U_e, the magnetic energy U_m, and the total energy U as functions of time.

Picture the Problem We can differentiate Q with respect to time to find I as a function of time. In (*b*) we can find C by using $\omega = 1/\sqrt{LC}$. The energy stored in the magnetic field of the inductor is given by $U_m = \frac{1}{2}LI^2$ and the energy stored in the electric field of the capacitor by $U_e = \frac{1}{2}\frac{Q^2}{C}$.

(*a*) Differentiate the charge with respect to time to obtain the current:

$$I(t) = \frac{dQ}{dt} = \frac{d}{dt}\left[(15\ \mu\text{C})\cos\left(\omega t + \frac{\pi}{4}\right)\right] = -(15\ \mu\text{C})\left(1250\,\text{s}^{-1}\right)\sin\left(\omega t + \frac{\pi}{4}\right)$$

$$= -(18.75\,\text{mA})\sin\left(\omega t + \frac{\pi}{4}\right) = \boxed{-(19\,\text{mA})\sin\left(\omega t + \frac{\pi}{4}\right)}$$

where $\omega = 1250$ rad/s

(*b*) Relate C to L and ω:

$$\omega = \frac{1}{\sqrt{LC}}$$

Solve for C to obtain:

$$C = \frac{1}{\omega^2 L}$$

Substitute numerical values and evaluate C:

$$C = \frac{1}{\left(1250\,\text{s}^{-1}\right)^2(28\,\text{mH})} = 22.86\ \mu\text{F}$$

$$= \boxed{23\ \mu\text{F}}$$

(*c*) Express and evaluate the magnetic energy $U_m(t)$:

$$U_m(t) = \tfrac{1}{2}LI^2 = \tfrac{1}{2}(28\,\text{mH})(18.75\,\text{mA})^2\sin^2\left(\omega t + \frac{\pi}{4}\right) = \boxed{(4.9\ \mu\text{J})\sin^2\left(\omega t + \frac{\pi}{4}\right)}$$

where $\omega = 1250$ rad/s

Use $U_e = \frac{1}{2}\frac{Q^2}{C}$ to find the electrical energy stored in the capacitor as a function of time:

$$U_e(t) = \frac{1}{2}\frac{(15\,\mu\text{F})^2}{22.86\,\mu\text{F}}\cos^2\left(\omega t + \frac{\pi}{4}\right)$$
$$= (4.92\,\mu\text{J})\cos^2\left(\omega t + \frac{\pi}{4}\right)$$
$$= \boxed{(4.9\,\mu\text{J})\cos^2\left(\omega t + \frac{\pi}{4}\right)}$$

where $\omega = 1250$ rad/s

The total energy stored in the electric and magnetic fields is the sum of $U_m(t)$ and $U_e(t)$:

$$U = (4.92\,\mu\text{J})\sin^2\left(\omega t + \frac{\pi}{4}\right) + (4.92\,\mu\text{J})\cos^2\left(\omega t + \frac{\pi}{4}\right) = \boxed{4.9\,\mu\text{J}}$$

where $\omega = 1250$ rad/s.

60 ••• One method for determining the compressibility of a dielectric material uses a driven *LC* circuit that has a parallel-plate capacitor. The dielectric is inserted between the plates and the change in resonance frequency is determined as the capacitor plates are subjected to a compressive stress. In one such arrangement, the resonance frequency is 120 MHz when a dielectric of thickness 0.100 cm and dielectric constant $\kappa = 6.80$ is placed between the plates. Under a compressive stress of 800 atm, the resonance frequency decreases to 116 MHz. Find the Young's modulus of the dielectric material. (Assume that the dielectric constant does not change with pressure.)

Picture the Problem We can use the definition of the capacitance of a dielectric-filled capacitor and the expression for the resonance frequency of an *LC* circuit to derive an expression for the fractional change in the thickness of the dielectric in terms of the resonance frequency and the frequency of the circuit when the dielectric is under compression. We can then use this expression for $\Delta t/t$ to calculate the value of Young's modulus for the dielectric material.

Use its definition to express Young's modulus of the dielectric material:

$$Y = \frac{\text{stress}}{\text{strain}} = \frac{\Delta P}{\Delta t/t} \qquad (1)$$

Letting t be the initial thickness of the dielectric, express the initial capacitance of the capacitor:

$$C_0 = \frac{\kappa \in_0 A}{t}$$

Express the capacitance of the capacitor when it is under compression:

$$C_c = \frac{\kappa \in_0 A}{t - \Delta t}$$

Express the resonance frequency of the capacitor before the dielectric is compressed:

$$\omega_0 = \frac{1}{\sqrt{C_0 L}} = \frac{1}{\sqrt{\frac{\kappa \in_0 AL}{t}}}$$

When the dielectric is compressed:

$$\omega_c = \frac{1}{\sqrt{C_c L}} = \frac{1}{\sqrt{\frac{\kappa \in_0 AL}{t - \Delta t}}}$$

Express the ratio of ω_c to ω_0 and simplify to obtain:

$$\frac{\omega_c}{\omega_0} = \frac{\sqrt{\frac{\kappa \in_0 AL}{t}}}{\sqrt{\frac{\kappa \in_0 AL}{t - \Delta t}}} = \sqrt{1 - \frac{\Delta t}{t}}$$

Expand the radical binomially to obtain:

$$\frac{\omega_c}{\omega_0} = \left(1 - \frac{\Delta t}{t}\right)^{1/2} \approx 1 - \frac{\Delta t}{2t}$$

provided $\Delta t << t$.

Solve for $\Delta t/t$:

$$\frac{\Delta t}{t} = 2\left(1 - \frac{\omega_c}{\omega_0}\right)$$

Substitute in equation (1) to obtain:

$$Y = \frac{\Delta P}{2\left(1 - \frac{\omega_c}{\omega_0}\right)}$$

Substitute numerical values and evaluate Y:

$$Y = \frac{(800\,\text{atm})(101.325\,\text{kPa/atm})}{2\left(1 - \frac{116\,\text{MHz}}{120\,\text{MHz}}\right)} = \boxed{1.22 \times 10^9\ \text{N/m}^2}$$

61 ••• Figure 29-41 shows an inductor in series with a parallel plate capacitor. The capacitor has a width w of 20 cm and a gap of 2.0 mm. A dielectric that has a dielectric constant of 4.8 can be slid in and out of the gap. The inductor has an inductance of 2.0 mH. When half the dielectric is between the capacitor plates (when $x = \frac{1}{2}w$), the resonant frequency of this combination is 90 MHz.
(a) What is the capacitance of the capacitor without the dielectric?
(b) Find the resonance frequency as a function of x for $0 \le x \le w$.

Picture the Problem We can model this capacitor as the equivalent of two capacitors connected in parallel. Let C_1 be the capacitance of the dielectric-filled capacitor and C_2 be the capacitance of the air-filled capacitor. We'll derive expressions for the capacitances of the parallel capacitors and add these expressions to obtain $C(x)$. We can then use the given resonance frequency when $x = w/2$ and the given value for L to evaluate C_0. In Part (b) we can use our result for $C(x)$ and the relationship between f, L, and $C(x)$ at resonance to express $f(x)$.

(a) Express the equivalent capacitance of the two capacitors in parallel:

$$C(x) = C_1 + C_2 = \frac{\kappa \in_0 A_1}{d} + \frac{\in_0 A_2}{d} \quad (1)$$

Express A_2 in terms of the total area of a capacitor plate A, w, and the distance x:

$$\frac{A_2}{A} = \frac{x}{w} \Rightarrow A_2 = A\frac{x}{w}$$

Express A_1 in terms of A and A_2:

$$A_1 = A - A_2 = A\left(1 - \frac{x}{w}\right)$$

Substitute in equation (1) and simplify to obtain:

$$C(x) = \frac{\kappa \in_0 A}{d}\left(1 - \frac{x}{w}\right) + \frac{\in_0 A}{d}\frac{x}{w}$$

$$= \frac{\in_0 A}{d}\left[\kappa\left(1 - \frac{x}{w}\right) + \frac{x}{w}\right]$$

$$= \kappa C_0\left[1 - \frac{\kappa - 1}{\kappa w}x\right]$$

where $C_0 = \dfrac{\in_0 A}{d}$

Find $C(w/2)$:

$$C\left(\frac{w}{2}\right) = \kappa C_0\left[1 - \frac{\kappa - 1}{\kappa w}\frac{w}{2}\right] = \kappa C_0\left[1 - \frac{\kappa - 1}{2\kappa}\right] = C_0\frac{\kappa + 1}{2}$$

Express the resonance frequency of the circuit in terms of L and $C(x)$:

$$f(x) = \frac{1}{2\pi\sqrt{LC(x)}} \qquad (2)$$

Evaluate $f(w/2)$:

$$f\left(\frac{w}{2}\right) = \frac{1}{2\pi\sqrt{LC_0\frac{\kappa + 1}{2}}} = \frac{1}{2\pi}\sqrt{\frac{2}{(\kappa + 1)LC_0}}$$

Solve for C_0 to obtain:

$$C_0 = \frac{1}{2\pi^2 f^2\left(\frac{w}{2}\right)L(\kappa + 1)}$$

Substitute numerical values and evaluate C_0:

$$C_0 = \frac{1}{2\pi^2(90\text{ MHz})^2\left(\frac{20\text{ cm}}{2}\right)(2.0\text{ mH})(4.8 + 1)} = \boxed{5.4\text{ fF}}$$

(*b*) Substitute for $C(x)$ in equation (2) to obtain:

$$f(x) = \frac{1}{2\pi\sqrt{L\kappa C_0\left[1 - \frac{\kappa - 1}{\kappa w}x\right]}}$$

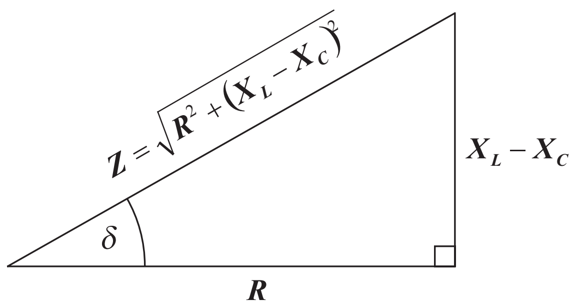
Substitute numerical values and evaluate $f(x)$:

$$f(x) = \frac{1}{2\pi\sqrt{(2.0\text{ mH})(4.8)(5.39\times10^{-16}\text{ F})\left[1 - \frac{4.8 - 1}{4.8(0.20\text{ m})}x\right]}} = \boxed{\frac{70\text{ MHz}}{\sqrt{1 - (4.0\text{ m}^{-1})x}}}$$

Driven *RLC* Circuits

62 • A circuit consists of an ideal ac generator, a 20-μF capacitor and an 80-Ω resistor, all connected in series. The output of the generator has a peak emf of 20-V, and the armature of the generator rotates at 400 rad/s. Find (*a*) the power factor, (*b*) the rms current, and (*c*) the average power supplied by the generator.

Picture the Problem The diagram shows the relationship between δ, X_L, X_C, and R. We can use this reference triangle to express the power factor for the given circuit. In (*b*) we can find the rms current from the rms potential difference and the impedance of the circuit. We can find the average power delivered by the source from the rms current and the resistance of the resistor.



(*a*) The power factor is defined to be:

$$\cos\delta = \frac{R}{Z} = \frac{R}{\sqrt{R^2 + (X_L - X_C)^2}}$$

With no inductance in the circuit:

$$X_L = 0$$

and

$$\cos\delta = \frac{R}{\sqrt{R^2 + X_C^2}} = \frac{R}{\sqrt{R^2 + \dfrac{1}{\omega^2 C^2}}}$$

Substitute numerical values and evaluate $\cos\delta$:

$$\cos\delta = \frac{80\,\Omega}{\sqrt{(80\,\Omega)^2 + \dfrac{1}{(400\,\text{s}^{-1})^2 (20\,\mu\text{F})^2}}} = \boxed{0.54}$$

(*b*) Express the rms current in the circuit:

$$I_{\text{rms}} = \frac{\mathcal{E}_{\text{rms}}}{Z} = \frac{\dfrac{\mathcal{E}_{\max}}{\sqrt{2}}}{\sqrt{R^2 + X_C^2}} = \frac{\mathcal{E}_{\max}}{\sqrt{2}\sqrt{R^2 + \dfrac{1}{\omega^2 C^2}}}$$

Substitute numerical values and evaluate I_{rms}:

$$I_{\text{rms}} = \frac{20\,\text{V}}{\sqrt{2}\sqrt{(80\,\Omega)^2 + \dfrac{1}{(400\,\text{s}^{-1})^2(20\,\mu\text{F})^2}}} = 95.3\,\text{mA} = \boxed{95\,\text{mA}}$$

(*c*) The average power delivered by the generator is given by:

$$P_{\text{av}} = I_{\text{rms}}^2 R$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}} = (95.3\,\text{mA})^2(80\,\Omega) = \boxed{0.73\,\text{W}}$$

63 •• **[SSM]** Show that the expression $P_{\text{av}} = R\mathcal{E}_{\text{rms}}^2 / Z^2$ gives the correct result for a circuit containing only an ideal ac generator and (*a*) a resistor, (*b*) a capacitor, and (*c*) an inductor. In the expression $P_{\text{av}} = R\mathcal{E}_{\text{rms}}^2 / Z^2$, P_{av} is the average power supplied by the generator, $\mathcal{E}_{\text{rms}}$ is the root-mean-square of the emf of the generator, *R* is the resistance, *C* is the capacitance and *L* is the inductance. (In Part (*a*), $C = L = 0$, in Part (*b*), $R = L = 0$ and in Part (*c*), $R = C = 0$.

Picture the Problem The impedance of an ac circuit is given by $Z = \sqrt{R^2 + (X_L - X_C)^2}$. We can evaluate the given expression for P_{av} first for $X_L = X_C = 0$ and then for $R = 0$.

(*a*) For $X = 0$, $Z = R$ and:

$$P_{\text{av}} = \frac{R\mathcal{E}_{\text{rms}}^2}{Z^2} = \frac{R\mathcal{E}_{\text{rms}}^2}{R^2} = \boxed{\frac{\mathcal{E}_{\text{rms}}^2}{R}}$$

(*b*) and (*c*) If $R = 0$, then:

$$P_{\text{av}} = \frac{R\mathcal{E}_{\text{rms}}^2}{Z^2} = \frac{(0)\mathcal{E}_{\text{rms}}^2}{(X_L - X_C)^2} = \boxed{0}$$

Remarks: Recall that there is no energy dissipation in an ideal inductor or capacitor.

64 •• A series *RLC* circuit that has an inductance of 10 mH, a capacitance of 2.0 μF, and a resistance of 5.0 Ω is driven by an ideal ac voltage source that has a peak emf of 100 V. Find (*a*) the resonant frequency and (*b*) the root-mean-square current at resonance. When the frequency is 8000 rad/s, find (*c*) the capacitive and inductive reactances, (*d*) the impedance, (*e*) the root-mean-square current, and (*f*) the phase angle.

Picture the Problem We can use $\omega_0 = 1/\sqrt{LC}$ to find the resonant frequency of the circuit, $I_{\text{rms}} = \mathcal{E}_{\text{rms}}/R$ to find the rms current at resonance, the definitions of X_C and X_L to find these reactances at ω = 8000 rad/s, the definitions of Z and I_{rms} to find the impedance and rms current at ω = 8000 rad/s, and the definition of the phase angle to find δ.

(*a*) Express the resonant frequency ω_0 in terms of L and C:

$$\omega_0 = \frac{1}{\sqrt{LC}}$$

Substitute numerical values and evaluate ω_0:

$$\omega_0 = \frac{1}{\sqrt{(10\,\text{mH})(2.0\,\mu\text{F})}} = \boxed{7.1\times10^3\ \text{rad/s}}$$

(*b*) Relate the rms current at resonance to $\mathcal{E}_{\text{rms}}$ and the impedance of the circuit at resonance:

$$I_{\text{rms}} = \frac{\mathcal{E}_{\text{rms}}}{R} = \frac{\mathcal{E}_{\max}}{\sqrt{2}R} = \frac{100\,\text{V}}{\sqrt{2}(5.0\,\Omega)} = \boxed{14\,\text{A}}$$

(*c*) Express and evaluate X_C and X_L at ω = 8000 rad/s:

$$X_C = \frac{1}{\omega C} = \frac{1}{(8000\,\text{s}^{-1})(2.0\,\mu\text{F})} = 62.50\,\Omega = \boxed{63\,\Omega}$$

and

$$X_L = \omega L = (8000\,\text{s}^{-1})(10\,\text{mH}) = \boxed{80\,\Omega}$$

(*d*) Express the impedance in terms of the reactances, substitute the results from (*c*), and evaluate Z:

$$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(5.0\,\Omega)^2 + (80\,\Omega - 62.5\,\Omega)^2} = 18.2\,\Omega = \boxed{18\,\Omega}$$

(*e*) Relate the rms current at ω = 8000 rad/s to $\mathcal{E}_{\text{rms}}$ and the impedance of the circuit at this frequency:

$$I_{\text{rms}} = \frac{\mathcal{E}_{\text{rms}}}{Z} = \frac{\mathcal{E}_{\max}}{\sqrt{2}Z} = \frac{100\,\text{V}}{\sqrt{2}(18.2\,\Omega)} = \boxed{3.9\,\text{A}}$$

(*f*) δ is given by:

$$\delta = \tan^{-1}\left(\frac{X_L - X_C}{R}\right)$$

Substitute numerical values and evaluate δ:

$$\delta = \tan^{-1}\left(\frac{80\,\Omega - 62.5\,\Omega}{5.0\,\Omega}\right) = \boxed{74°}$$

65 •• **[SSM]** Find (*a*) the *Q* factor and (*b*) the resonance width (in hertz) for the circuit in Problem 64. (*c*) What is the power factor when ω = 8000 rad/s?

Picture the Problem The *Q* factor of the circuit is given by $Q = \omega_0 L/R$, the resonance width by $\Delta f = f_0/Q = \omega_0/2\pi Q$, and the power factor by $\cos\delta = R/Z$. Because *Z* is frequency dependent, we'll need to find X_C and X_L at ω = 8000 rad/s in order to evaluate $\cos\delta$.

Using their definitions, express the *Q* factor and the resonance width of the circuit:

$$Q = \frac{\omega_0 L}{R} \qquad (1)$$

and

$$\Delta f = \frac{f_0}{Q} = \frac{\omega_0}{2\pi Q} \qquad (2)$$

(*a*) Express the resonance frequency for the circuit:

$$\omega_0 = \frac{1}{\sqrt{LC}}$$

Substituting for ω_0 in equation (1) yields:

$$Q = \frac{L}{\sqrt{LC}\,R} = \frac{1}{R}\sqrt{\frac{L}{C}}$$

Substitute numerical values and evaluate *Q*:

$$Q = \frac{1}{5.0\,\Omega}\sqrt{\frac{10\text{ mH}}{2.0\ \mu\text{F}}} = 14.1 = \boxed{14}$$

(*b*) Substitute numerical values in equation (2) and evaluate Δf:

$$\Delta f = \frac{7.07\times10^3\text{ rad/s}}{2\pi(14.1)} = \boxed{80\,\text{Hz}}$$

(*c*) The power factor of the circuit is given by:

$$\cos\delta = \frac{R}{Z} = \frac{R}{\sqrt{R^2 + (X_L - X_C)^2}} = \frac{R}{\sqrt{R^2 + \left(\omega L - \dfrac{1}{\omega C}\right)^2}}$$

Substitute numerical values and evaluate $\cos\delta$:

$$\cos\delta = \frac{5.0\,\Omega}{\sqrt{(5.0\,\Omega)^2 + \left((8000\,\text{s}^{-1})(10\,\text{mH}) - \frac{1}{(8000\,\text{s}^{-1})(2.0\,\mu\text{F})}\right)^2}} = \boxed{0.27}$$

66 •• FM radio stations typically operate at frequencies separated by 0.20 MHz. Thus, when your radio is tuned to a station operating at a frequency of 100.1 MHz, the resonance width of the receiver circuit should be much smaller than 0.20 MHz, so that you do not receive a signal from stations operating at adjacent frequencies. Assume your receiving circuit has a resonance width of 0.050 MHz. When tuned in to this particular station, what is the *Q* factor of your circuit?

Picture the Problem We can use its definition, $Q = f_0/\Delta f$ to find the *Q* factor for the circuit.

The *Q* factor for the circuit is given by:

$$Q = \frac{f_0}{\Delta f}$$

Substitute numerical values and evaluate *Q*:

$$Q = \frac{100.1\,\text{MHz}}{0.050\,\text{MHz}} \approx \boxed{2.0\times10^3}$$

67 •• A coil is connected to a 60-Hz ac generator with a peak emf equal to 100 V. At this frequency, the coil has an impedance of 10 Ω and a reactance of 8.0 Ω. (*a*) What is the peak current in the coil? (*b*) What is the phase angle between the current and the applied voltage? (*c*) A capacitor is put in series with the coil and the generator. What capacitance is required so that the current is in phase with the generator emf? (*d*) What is the peak voltage measured across this capacitor?

Picture the Problem We can use $I_{\text{peak}} = \mathcal{E}_{\text{peak}}/Z$ to find the current in the coil and the definition of the phase angle to evaluate δ. We can equate X_L and X_C to find the capacitance required so that the current and the voltage are in phase. Finally, we can find the voltage measured across the capacitor by using $V_C = IX_C$.

(*a*) Express the current in the coil in terms of the potential difference across it and its impedance:

$$I_{\text{peak}} = \frac{\mathcal{E}_{\text{peak}}}{Z}$$

Substitute numerical values and evaluate I_{peak}:

$$I_{\text{peak}} = \frac{100\,\text{V}}{10\,\Omega} = \boxed{10\,\text{A}}$$

(*b*) The phase angle δ is given by:

$$\delta = \cos^{-1}\left(\frac{R}{Z}\right) = \sin^{-1}\left(\frac{X_L}{Z}\right)$$

Substitute numerical values and evaluate δ:

$$\delta = \sin^{-1}\left(\frac{8.0\,\Omega}{10\,\Omega}\right) = \boxed{53°}$$

(*c*) Express the condition on the reactances that must be satisfied if the current and voltage are to be in phase:

$$X_L = X_C = \frac{1}{\omega C} \Rightarrow C = \frac{1}{\omega X_L} = \frac{1}{2\pi f X_L}$$

Substitute numerical values and evaluate C:

$$C = \frac{1}{2\pi\left(60\,\text{s}^{-1}\right)\left(8.0\,\Omega\right)} = 332\,\mu\text{F}$$
$$= \boxed{0.33\,\text{mF}}$$

(*d*) Express the potential difference across the capacitor:

$$V_C = I_{\text{peak}} X_C$$

Relate the peak current in the circuit to the impedance of the circuit when $X_L = X_C$:

$$I_{\text{peak}} = \frac{V_{\text{peak}}}{R}$$

Substitute for I to obtain:

$$V_C = \frac{V_{\text{peak}} X_C}{R} = \frac{V_{\text{peak}}}{2\pi f C R}$$

Relate the impedance of the circuit to the resistance of the coil:

$$Z = \sqrt{R^2 + X^2} \Rightarrow R = \sqrt{Z^2 - X^2}$$

Substituting for R yields:

$$V_C = \frac{V_{\text{peak}}}{2\pi f C\sqrt{Z^2 - X^2}}$$

Substitute numerical values and evaluate V_C:

$$V_C = \frac{100\,\text{V}}{2\pi\left(60\,\text{s}^{-1}\right)\left(332\,\mu\text{F}\right)\sqrt{\left(10\,\Omega\right)^2 - \left(8.0\,\Omega\right)^2}} = \boxed{0.13\,\text{kV}}$$

68 •• An ideal 0.25-H inductor and a capacitor are connected in series with an ideal 60-Hz generator. An digital voltmeter is used to measure the rms voltages across the inductor and capacitor independently. The voltmeter reading across the capacitor is 75 V and that across the inductor is 50 V. (*a*) Find the capacitance and the rms current in the circuit. (*b*) What is the rms voltage across the series combination of the capacitor and the inductor?

Picture the Problem We can find C using $V_C = I_{\text{rms}}X_C$ and I_{rms} from the potential difference across the inductor. In the absence of resistance in the circuit, the measured rms voltage across both the capacitor and inductor is $V = |V_L - V_C|$.

(*a*) Relate the capacitance C to the potential difference across the capacitor:

$$V_C = I_{\text{rms}}X_C = \frac{I_{\text{rms}}}{2\pi fC} \Rightarrow C = \frac{I_{\text{rms}}}{2\pi fV_C}$$

Use the potential difference across the inductor to express the rms current in the circuit:

$$I_{\text{rms}} = \frac{V_L}{X_L} = \frac{V_L}{2\pi fL}$$

Substitute for I_{rms} to obtain:

$$C = \frac{V_L}{(2\pi f)^2 LV_C}$$

Substitute numerical values and evaluate C:

$$C = \frac{50\,\text{V}}{\left[2\pi\left(60\,\text{s}^{-1}\right)\right]^2(0.25\,\text{H})(75\,\text{V})} = \boxed{19\,\mu\text{F}}$$

(*b*) Express the measured rms voltage V across both the capacitor and the inductor when $R = 0$:

$$V = |V_L - V_C|$$

Substitute numerical values and evaluate V:

$$V = |50\,\text{V} - 75\,\text{V}| = \boxed{25\,\text{V}}$$

69 •• **[SSM]** In the circuit shown in Figure 29-42 the ideal generator produces an rms voltage of 115 V when operated at 60 Hz. What is the rms voltage between points (*a*) *A* and *B*, (*b*) *B* and *C*, (*c*) *C* and *D*, (*d*) *A* and *C*, and (*e*) *B* and *D*?

Picture the Problem We can find the rms current in the circuit and then use it to find the potential differences across each of the circuit elements. We can use phasor diagrams and our knowledge of the phase shifts between the voltages across the three circuit elements to find the voltage differences across their combinations.

(*a*) Express the potential difference between points *A* and *B* in terms of I_{rms} and X_L:

$$V_{AB} = I_{\text{rms}} X_L \qquad (1)$$

Express I_{rms} in terms of $\mathcal{E}$ and Z:

$$I_{\text{rms}} = \frac{\mathcal{E}}{Z} = \frac{\mathcal{E}}{\sqrt{R^2 + (X_L - X_C)^2}}$$

Evaluate X_L and X_C to obtain:

$$X_L = 2\pi fL = 2\pi(60\,\text{s}^{-1})(137\,\text{mH}) = 51.648\,\Omega$$

and

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(60\,\text{s}^{-1})(25\,\mu\text{F})} = 106.10\,\Omega$$

Substitute numerical values and evaluate I_{rms}:

$$I_{\text{rms}} = \frac{115\,\text{V}}{\sqrt{(50\,\Omega)^2 + (51.648\,\Omega - 106.10\,\Omega)^2}} = 1.5556\,\text{A}$$

Substitute numerical values in equation (1) and evaluate V_{AB}:

$$V_{AB} = (1.5556\,\text{A})(51.648\,\Omega) = 80.344\text{ V} = \boxed{80\,\text{V}}$$

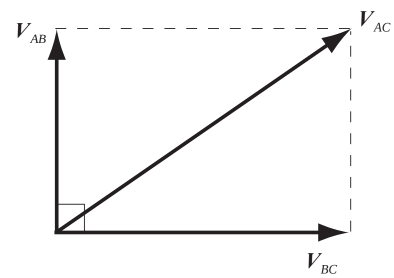
(*b*) Express the potential difference between points *B* and *C* in terms of I_{rms} and R:

$$V_{BC} = I_{\text{rms}} R = (1.5556\,\text{A})(50\,\Omega) = 77.780\text{ V} = \boxed{78\,\text{V}}$$

(*c*) Express the potential difference between points *C* and *D* in terms of I_{rms} and X_C:

$$V_{CD} = I_{\text{rms}} X_C = (1.5556\,\text{A})(106.10\,\Omega) = 165.05\,\text{V} = \boxed{0.17\,\text{kV}}$$

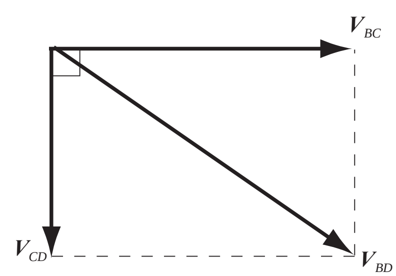
(d) The voltage across the inductor leads the voltage across the resistor as shown in the phasor diagram to the right:



Use the Pythagorean theorem to find V_{AC}:

$$V_{AC} = \sqrt{V_{AB}^2 + V_{BC}^2} = \sqrt{(80.0\,\text{V})^2 + (77.780\,\text{V})^2} = 111.58\,\text{V} = \boxed{0.11\,\text{kV}}$$

(e) The voltage across the capacitor lags the voltage across the resistor as shown in the phasor diagram to the right:



Use the Pythagorean theorem to find V_{BD}:

$$V_{BD} = \sqrt{V_{CD}^2 + V_{BC}^2} = \sqrt{(165.05\,\text{V})^2 + (77.780\,\text{V})^2} = 182.46\,\text{V} = \boxed{0.18\,\text{kV}}$$

70 •• When an *RLC* series circuit is connected to a 120-V rms, 60-Hz line, the rms current in the circuit is 11 A and this current leads the line voltage by 45º. (a) Find the average power supplied to the circuit. (b) What is the resistance in the circuit? (c) If the inductance in the circuit is 50 mH, find the capacitance in the circuit. (d) Without changing the inductance, by how much should you change the capacitance to make the power factor equal to 1? (e) Without changing the capacitance, by how much should you change the inductance to make the power factor equal to 1?

Picture the Problem We can use $P_{\text{av}} = \mathcal{E}_{\text{rms}} I_{\text{rms}} \cos\delta$ to find the power supplied to the circuit and $P_{\text{av}} = I_{\text{rms}}^2 R$ to find the resistance. In Part (c) we can relate the capacitive reactance to the impedance, inductive reactance, and resistance of the circuit and solve for the capacitance C. We can use the condition on X_L and X_C at resonance to find the capacitance or inductance you would need to add to the circuit to make the power factor equal to 1.

(*a*) Express the power supplied to the circuit in terms of $\mathcal{E}_{\text{rms}}$, I_{rms}, and the power factor $\cos\delta$:

$$P_{\text{av}} = \mathcal{E}_{\text{rms}} I_{\text{rms}} \cos\delta$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}} = (120\,\text{V})(11\,\text{A})\cos 45° = 933\,\text{W} = \boxed{0.93\,\text{kW}}$$

(*b*) Relate the power dissipated in the circuit to the resistance of the resistor:

$$P_{\text{av}} = I_{\text{rms}}^2 R \Rightarrow R = \frac{P_{\text{av}}}{I_{\text{rms}}^2}$$

Substitute numerical values and evaluate *R*:

$$R = \frac{933\,\text{W}}{(11\,\text{A})^2} = 7.71\,\Omega = \boxed{7.7\,\Omega}$$

(*c*) Express the capacitance of the capacitor in terms of its reactance:

$$C = \frac{1}{\omega X_C} = \frac{1}{2\pi f X_C} \qquad (1)$$

Relate the capacitive reactance to the impedance, inductive reactance, and resistance of the circuit:

$$Z^2 = R^2 + (X_L - X_C)^2$$

Express the impedance of the circuit in terms of the rms emf $\mathcal{E}$ and the rms current I_{rms}:

$$Z^2 = \frac{\mathcal{E}^2}{I_{\text{rms}}^2}$$

Equating these two expressions yields:

$$\frac{\mathcal{E}^2}{I_{\text{rms}}^2} = R^2 + (X_L - X_C)^2$$

Solve for $|X_L - X_C|$:

$$|X_L - X_C| = \sqrt{\frac{\mathcal{E}^2}{I_{\text{rms}}^2} - R^2}$$

Note that because *I* leads $\mathcal{E}$, the circuit is capacitive and $X_C > X_L$. Hence:

$$|X_L - X_C| = -(X_L - X_C)$$

and

$$X_C = X_L + \sqrt{\frac{\mathcal{E}^2}{I_{\text{rms}}^2} - R^2} = 2\pi f L + \sqrt{\frac{\mathcal{E}^2}{I_{\text{rms}}^2} - R^2}$$

Substitute numerical values and evaluate X_C:

$$X_C = 2\pi\left(60\,\text{s}^{-1}\right)\left(50\,\text{mH}\right) + \sqrt{\frac{\left(120\,\text{V}\right)^2}{\left(11\,\text{A}\right)^2} - \left(7.71\,\Omega\right)^2}$$
$$= 18.8\,\Omega + 7.7\,\Omega = 26.6\,\Omega$$

Substitute in equation (1) and evaluate C:

$$C = \frac{1}{2\pi\left(60\,\text{s}^{-1}\right)\left(26.6\,\Omega\right)} = 99.7\,\mu\text{F}$$
$$= \boxed{0.10\,\text{mF}}$$

(*d*) Let $C_{\text{pf}=1}$ represent the capacitance required to make $\cos\delta = 1$. The necessary change in capacitance is given by:

$$\Delta C = C_{\text{pf}=1} - C = C_{\text{pf}=1} - 99.9\,\mu\text{F}$$

Relate $C_{\text{pf}=1}$ to X_L:

$$X_L = X_C = \frac{1}{2\pi f C_{\text{pf}=1}}$$

Solving for $C_{\text{pf}=1}$ yields:

$$C_{\text{pf}=1} = \frac{1}{2\pi f X_L}$$

Substitute for $C_{\text{pf}=1}$ in the expression for ΔC to obtain:

$$\Delta C = \frac{1}{2\pi f X_L} - 99.9\,\mu\text{F}$$

Substitute numerical values and evaluate ΔC:

$$\Delta C = \frac{1}{2\pi\left(60\,\text{s}^{-1}\right)\left(18.8\,\Omega\right)} - 99.9\,\mu\text{F}$$
$$= \boxed{41\,\mu\text{F}}$$

(*e*) Let $L_{\text{pf}=1}$ represent the inductance required to make $\cos\delta = 1$. The necessary change in inductance is given by:

$$\Delta L = L_{\text{pf}=1} - L = L_{\text{pf}=1} - 50\,\text{mH}$$

Relate $L_{\text{pf}=1}$ to X_C:

$$X_L = X_C = 2\pi f L_{\text{pf}=1}$$

Solving for $L_{\text{pf}=1}$ yields:

$$L_{\text{pf}=1} = \frac{X_C}{2\pi f}$$

Substitute for $L_{\text{pf}=1}$ in the expression for ΔL to obtain:

$$\Delta L = \frac{X_C}{2\pi f} - 50\text{ mH}$$

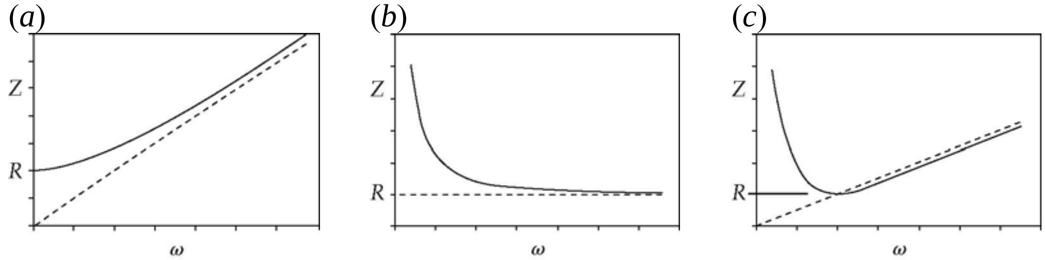
Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{26.6\,\Omega}{2\pi\left(60\text{ s}^{-1}\right)} - 50\text{ mH} = \boxed{21\text{mH}}$$

71 •• Plot the circuit impedance versus the angular frequency for each of the following circuits. (*a*) A driven series *LR* circuit, (*b*) a driven series *RC* circuit, and (*c*) a driven series *RLC* circuit.

Picture the Problem The impedance for the three circuits as functions of the angular frequency is shown in the three figures below. Also shown in each figure (dashed line) is the asymptotic approach for large angular frequencies.

(*a*) (*b*) (*c*)



72 •• In a driven series *RLC* circuit, the ideal generator has a peak emf equal to 200 V, the resistance is 60.0 Ω and the capacitance is 8.00 μF. The inductance can be varied from 8.00 mH to 40.0 mH by the insertion of an iron core in the solenoid. The angular frequency of the generator is 2500 rad/s. If the capacitor voltage is not to exceed 150 V, find (*a*) the peak current and (*b*) the range of inductances that is safe to use.

Picture the Problem We can find the maximum current in the circuit from the maximum voltage across the capacitor and the reactance of the capacitor. To find the range of inductance that is safe to use we can express Z^2 for the circuit in terms of $\mathcal{E}_{\text{peak}}^2$ and I_{peak}^2 and solve the resulting quadratic equation for *L*.

(*a*) Express the peak current in terms of the maximum potential difference across the capacitor and its reactance:

$$I_{\text{peak}} = \frac{V_{C,\text{peak}}}{X_C} = \omega C V_{C,\text{peak}}$$

Substitute numerical values and evaluate I_{peak}:

$$I_{\text{peak}} = (2500\text{ rad/s})(8.00\,\mu\text{F})(150\text{ V}) = \boxed{3.00\text{ A}}$$

(*b*) Relate the maximum current in the circuit to the emf of the source and the impedance of the circuit:

$$I_{\text{peak}} = \frac{\mathcal{E}_{\text{peak}}}{Z} \Rightarrow Z^2 = \frac{\mathcal{E}_{\text{peak}}^2}{I_{\text{peak}}^2}$$

Express Z^2 in terms of R, X_L, and X_C:

$$Z^2 = R^2 + (X_L - X_C)^2$$

Substitute to obtain:

$$\frac{\mathcal{E}_{\text{peak}}^2}{I_{\text{peak}}^2} = R^2 + (X_L - X_C)^2$$

Evaluating X_C yields:

$$X_C = \frac{1}{\omega C} = \frac{1}{(2500\,\text{rad/s})(8.00\,\mu\text{F})} = 50.0\,\Omega$$

Substitute numerical values to obtain:

$$\frac{(200\,\text{V})^2}{(3.00\,\text{A})^2} = (60.0\,\Omega)^2 + ((2500\,\text{rad/s})L - 50.0\,\Omega)^2$$

Solving for L yields:

$$L = \frac{50.0\,\Omega \pm \sqrt{844\,\Omega^2}}{2500\,\text{s}^{-1}}$$

Denoting the solutions as L_+ and L_-, find the values for the inductance:

$$L_+ = 31.6\,\text{mH and } L_- = 8.38\,\text{mH}$$

The ranges for L are:

$$\boxed{8.00\,\text{mH} < L < 8.38\,\text{mH}}$$

and

$$\boxed{31.6\,\text{mH} < L < 40.0\,\text{mH}}$$

73 •• A certain electrical device draws an rms current of 10 A at an average power of 720 W when connected to a 120-V rms, 60-Hz power line. (*a*) What is the impedance of the device? (*b*) What series combination of resistance and reactance would have the same impedance as this device? (*c*) If the current leads the emf, is the reactance inductive or capacitive?

Picture the Problem We can find the impedance of the circuit from the applied emf and the current drawn by the device. In Part (*b*) we can use $P_{\text{av}} = I_{\text{rms}}^2 R$ to find R and the definition of the impedance of a series *RLC* circuit to find $X = X_L - X_C$.

(*a*) Express the impedance of the device in terms of the current it draws and the emf provided by the power line:

$$Z = \frac{\mathcal{E}_{\text{rms}}}{I_{\text{rms}}}$$

Substitute numerical values and evaluate *Z*:

$$Z = \frac{120\,\text{V}}{10\,\text{A}} = \boxed{12\,\Omega}$$

(*b*) Use the relationship between the average power supplied to the device and the rms current it draws to express *R*:

$$P_{\text{av}} = I_{\text{rms}}^2 R \Rightarrow R = \frac{P_{\text{av}}}{I_{\text{rms}}^2}$$

Substitute numerical values and evaluate *R*:

$$R = \frac{720\,\text{W}}{(10\,\text{A})^2} = 7.20\,\Omega = \boxed{7.2\,\Omega}$$

The impedance of a series *RLC* circuit is given by:

$$Z = \sqrt{R^2 + (X_L - X_C)^2}$$

or

$$Z^2 = R^2 + (X_L - X_C)^2$$

Solving for $X_L - X_C$ yields:

$$X = X_L - X_C = \sqrt{Z^2 - R^2}$$

Substitute numerical values and evaluate *X*:

$$X = \sqrt{(12\,\Omega)^2 - (7.20\,\Omega)^2} = \boxed{9.6\,\Omega}$$

(*c*) If the current leads the emf, the reactance is capacitive.

74 •• A method for measuring inductance is to connect the inductor in series with a known capacitance, a known resistance, an ac ammeter, and a variable-frequency signal generator. The frequency of the signal generator is varied and the emf is kept constant until the current is maximum. (*a*) If the capacitance is 10 μF, the peak emf is 10 V, the resistance is 100 Ω, and the rms current in the circuit is maximum when the driving frequency is 5000 rad/s, what is the value of the inductance? (*b*) What is the maximum rms current?

Picture the Problem (*a*) We can use the fact that when the current is a maximum, $X_L = X_C$, to find the inductance of the circuit. In Part (*b*), we can find $I_{\text{rms, max}}$ from $\mathcal{E}_{\text{peak}}$ and the impedance of the circuit at resonance.

(*a*) Relate X_L and X_C at resonance:

$$X_L = X_C \text{ or } \omega_0 L = \frac{1}{\omega_0 C}$$

Solve for L to obtain:

$$L = \frac{1}{\omega_0^2 C}$$

Substitute numerical values and evaluate L:

$$L = \frac{1}{\left(5000\,\text{s}^{-1}\right)^2\left(10\,\mu\text{F}\right)} = \boxed{4.0\,\text{mH}}$$

(*b*) Noting that, at resonance, $X = 0$, express $I_{\text{rms, max}}$ in terms of the applied emf and the impedance of the circuit at resonance:

$$I_{\text{rms, max}} = \frac{\mathcal{E}_{\text{rms}}}{Z} = \frac{\mathcal{E}_{\text{max}}}{\sqrt{2}Z} = \frac{10\,\text{V}}{\sqrt{2}\left(100\,\Omega\right)} = \boxed{71\,\text{mA}}$$

75 •• A resistor and a capacitor are connected in parallel across an ac generator (Figure 29-43) that has an emf given by $\mathcal{E} = \mathcal{E}_{\text{peak}} \cos \omega t$. (*a*) Show that the current in the resistor is given by $I_R = (\mathcal{E}_{\text{peak}}/R) \cos \omega t$. (*b*) Show that the current in the capacitor branch is given by $I_C = (\mathcal{E}_{\text{peak}}/X_C) \cos(\omega t + 90^\circ)$. (*c*) Show that the total current is given by $I = I_{\text{peak}} \cos(\omega t + \delta)$, where $\tan \delta = R/X_C$ and $I_{\text{peak}} = \mathcal{E}_{\text{peak}}/Z$.

Picture the Problem Because the resistor and the capacitor are connected in parallel, the voltage drops across them are equal. Also, the total current is the sum of the current through the resistor and the current through the capacitor. Because these two currents are not in phase, we use phasors to calculate their sum. The amplitudes of the applied voltage and the currents are equal to the magnitude of the phasors. That is $\left|\vec{\boldsymbol{\mathcal{E}}}\right| = \mathcal{E}_{\text{peak}}$, $\left|\vec{\boldsymbol{I}}\right| = I_{\text{peak}}$, $\left|\vec{\boldsymbol{I}}_R\right| = I_{R,\text{peak}}$, and $\left|\vec{\boldsymbol{I}}_C\right| = I_{C,\text{peak}}$.

(*a*) The ac source applies a voltage given by $\mathcal{E} = \mathcal{E}_{\text{peak}} \cos \omega t$. Thus, the voltage drop across both the load resistor and the capacitor is:

$$\mathcal{E}_{\text{peak}} \cos \omega t = I_R R$$

The current in the resistor is in phase with the applied voltage:

$$I_R = I_{R,\text{peak}} \cos \omega t$$

Because $I_{R,\text{peak}} = \dfrac{\mathcal{E}_{\text{peak}}}{R}$:

$$I_R = \boxed{\frac{\mathcal{E}_{\text{peak}}}{R} \cos \omega t}$$

(*b*) The current in the capacitor leads the applied voltage by 90°:

$$I_C = I_{C,\text{peak}}\cos(\omega t + 90°)$$

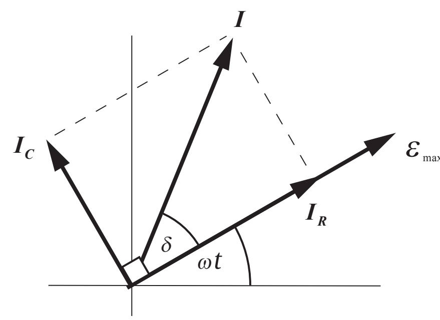
Because $I_{C,\text{peak}} = \dfrac{\mathcal{E}_{\text{peak}}}{X_C}$:

$$I_C = \boxed{\frac{\mathcal{E}_{\text{peak}}}{X_C}\cos(\omega t + 90°)}$$

(*c*) The net current *I* is the sum of the currents through the parallel branches:

$$I = I_R + I_C$$

Draw the phasor diagram for the circuit. The projections of the phasors onto the horizontal axis are the instantaneous values. The current in the resistor is in phase with the applied voltage, and the current in the capacitor leads the applied voltage by 90°. The net current phasor is the sum of the branch current phasors $\left(\vec{I} = \vec{I}_C + \vec{I}_R\right)$.



The peak current through the parallel combination is equal to $\mathcal{E}_{\text{peak}}/Z$, where *Z* is the impedance of the combination:

$$I = I_{\text{peak}}\cos(\omega t - |\delta|),$$

where $I_{\text{peak}} = \dfrac{\mathcal{E}_{\text{peak}}}{Z}$

From the phasor diagram we have:

$$I_{\text{peak}}^2 = I_{R,\text{peak}}^2 + I_{C,\text{peak}}^2$$

$$= \left(\frac{\mathcal{E}_{\text{peak}}}{R}\right)^2 + \left(\frac{\mathcal{E}_{\text{peak}}}{X_C}\right)^2$$

$$= \mathcal{E}_{\text{peak}}^2\left(\frac{1}{R^2} + \frac{1}{X_C^2}\right) = \frac{\mathcal{E}_{\text{peak}}^2}{Z^2}$$

where $\dfrac{1}{Z^2} = \dfrac{1}{R^2} + \dfrac{1}{X_C^2}$

Solving for I_{peak} yields:

$$I_{\text{peak}} = \boxed{\frac{\mathcal{E}_{\text{peak}}}{Z}} \text{ where } Z^{-2} = R^{-2} + X_C^{-2}$$

From the phasor diagram:

$$I = \boxed{I_{\text{peak}}\cos(\omega t + \delta)}$$

where

$$\tan\delta = \frac{I_C}{I_R} = \frac{\dfrac{\mathcal{E}_{\text{peak}}}{X_C}}{\dfrac{\mathcal{E}_{\text{peak}}}{R}} = \boxed{\frac{R}{X_C}}$$

76 ••• Figure 29-44 shows a plot of average power P_{av} versus generator frequency ω for a series *RLC* circuit driven by an ac generator. The average power P_{av} is given by Equation 29-56. The full width at half-maximum, $\Delta\omega$, is the width of the resonance curve between the two points, where P_{av} is one-half its maximum value. Show that for a sharply peaked resonance, $\Delta\omega \approx R/L$ and that $Q \approx \omega_0/\Delta\omega$ in this case (Equation 29-58). *Hint: The half-power points occur when the denominator of Equation 29-56 is equal to twice the value it has at resonance; that is, when* $L^2\left(\omega^2-\omega_0^2\right)+\omega^2R^2 \approx 2\omega_0^2R^2$. *Let* ω_1 *and* ω_2 *be the solutions of this equation. Then, show that* $\Delta\omega = \omega_2 - \omega_1 \approx R/L$.

Picture the Problem We can use the condition determining the half-power points to obtain a quadratic equation that we can solve for the frequencies corresponding to the half-power points. Letting ω_1 be the half-power frequency that is less than ω_0 and ω_2 be the half-power frequency that is greater than ω_0 will lead us to the result that $\Delta\omega = \omega_2 - \omega_1 \approx R/L$. We can then use the definition of Q to complete the proof that $Q \approx \omega_0/\Delta\omega$.

Equation 29-56 is:

$$P_{av} = \frac{V_{\text{app, rms}}^2 R\omega^2}{L^2\left(\omega^2-\omega_0^2\right)^2+\omega^2R^2}$$

The half-power points occur when the denominator of Equation 29-56 is twice the value near resonance; that is, when:

$$L^2\left(\omega^2-\omega_0^2\right)^2+\omega^2R^2 \approx 2\omega_0^2R^2$$

or

$$L^2\left[\left(\omega-\omega_0\right)\left(\omega+\omega_0\right)\right]^2+\omega^2R^2 \approx 2\omega_0^2R^2$$

For a sharply peaked resonance, $\omega+\omega_0 \approx 2\omega_0$. Hence:

$$L^2\left[\left(\omega-\omega_0\right)\left(2\omega_0\right)\right]^2+\omega^2R^2 \approx 2\omega_0^2R^2$$

or

$$4\omega_0^2L^2\left(\omega-\omega_0\right)^2+\omega^2R^2 \approx 2\omega_0^2R^2$$

Let ω_1 be a solution to this equation. Noting that, for a sharply peaked resonance, $\omega_1 \approx \omega_0$, it follows that:

$$4\omega_0^2L^2\left(\omega_1-\omega_0\right)^2+\omega_0^2R^2 \approx 2\omega_0^2R^2$$

or, simplifying,

$$\left(\omega_1-\omega_0\right)^2 \approx \frac{R^2}{4L^2}$$

Solving for ω_1 yields:

$$\omega_1 \approx \omega_0 - \frac{R}{2L}$$

where we've used the minus sign because $\omega_1 < \omega_0$.

Similarly for ω_2:

$$\omega_2 \approx \omega_0 + \frac{R}{2L}$$

where we've used the plus sign because $\omega_2 > \omega_0$.

Evaluating $\Delta\omega = \omega_2 - \omega_1$ yields:

$$\Delta\omega \approx \omega_0 + \frac{R}{2L} - \left(\omega_0 - \frac{R}{2L}\right) = \boxed{\frac{R}{L}}$$

From the definition of Q:

$$\frac{R}{L} = \frac{\omega_0}{Q}$$

Substitute in the expression for $\Delta\omega$ to obtain:

$$\Delta\omega \approx \frac{\omega_0}{Q} \Rightarrow Q \approx \boxed{\frac{\omega_0}{\Delta\omega}}$$

77 ••• Show by direct substitution that $L\dfrac{d^2Q}{dt^2} + R\dfrac{dQ}{dt} + \dfrac{1}{C}Q = 0$ (Equation 29-43*b*) is satisfied by $Q = Q_0e^{-t/\tau}\cos\omega' t$, where $\tau = 2L/R$, $\omega' = \sqrt{1/(LC) - 1/\tau^2}$, and Q_0 is the charge on the capacitor at $t = 0$.

Picture the Problem We'll differentiate $Q = Q_0e^{-t/\tau}\cos\omega' t$ twice and substitute this function and both its derivatives in the differential equation of the circuit. Rewriting the resulting equation in the form A$\cos\omega' t$ + B$\sin\omega' t$ = 0 will reveal that B vanishes. Requiring that A$\cos\omega' t = 0$ hold for all values of t will lead to the result that $\omega' = \sqrt{1/(LC) - 1/\tau^2}$.

Equation 29-43*b* is:

$$L\frac{d^2Q}{dt^2} + R\frac{dQ}{dt} + \frac{1}{C}Q = 0$$

Assume a solution of the form:

$$Q = Q_0e^{-t/\tau}\cos\omega' t$$

Differentiate $Q(t)$ twice to obtain:

$$\begin{aligned}\frac{dQ}{dt} &= Q_0\frac{d}{dt}\left[e^{-t/\tau}\cos\omega' t\right] \\ &= Q_0\left(e^{-t/\tau}\frac{d}{dt}\cos\omega' t + \cos\omega' t\frac{d}{dt}e^{-t/\tau}\right) \\ &= Q_0e^{-t/\tau}\left(-\omega'\sin\omega' t - \frac{1}{\tau}\cos\omega' t\right)\end{aligned}$$

and

$$\frac{d^2Q}{dt^2}=Q_0\frac{d}{dt}\left[e^{-t/\tau}\left(-\omega'\sin\omega't-\frac{1}{\tau}\cos\omega't\right)\right]$$
$$=Q_0e^{-t/\tau}\left[\left(\frac{1}{\tau^2}-\omega'^2\right)\cos\omega't+\frac{2\omega'}{\tau}\sin\omega't\right]$$

Substitute these derivatives in the differential equation and simplify to obtain:

$$LQ_0e^{-t/\tau}\left[\left(\frac{1}{\tau^2}-\omega'^2\right)\cos\omega't+\frac{2\omega'}{\tau}\sin\omega't\right]+RQ_0e^{-t/\tau}\left(-\omega'\sin\omega't-\frac{1}{\tau}\cos\omega't\right)$$
$$+\frac{1}{C}Q_0e^{-t/\tau}\cos\omega't=0$$

Because Q_0 and $e^{-t/\tau}$ are never zero, divide them out of the equation and simplify to obtain:

$$L\left(\frac{1}{\tau^2}-\omega'^2\right)\cos\omega't+\frac{2L\omega'}{\tau}\sin\omega't-\omega'R\sin\omega't-\frac{R}{\tau}\cos\omega't+\frac{1}{C}\cos\omega't=0$$

Rewriting this equation in the form A$\cos\omega't$ + B$\sin\omega't$ = 0 yields:

$$(R\omega'-R\omega')\sin\omega't+\left[L\left(\frac{1}{\tau^2}-\omega'^2\right)+\frac{1}{C}-\frac{R}{\tau}\right]\cos\omega't=0$$

or

$$\left[L\left(\frac{1}{\tau^2}-\omega'^2\right)+\frac{1}{C}-\frac{R}{\tau}\right]\cos\omega't=0$$

If this equation is to hold for all values of t, its coefficient must vanish:

$$L\left(\frac{1}{\tau^2}-\omega'^2\right)+\frac{1}{C}-\frac{R}{\tau}=0$$

Solving for ω' yields:

$$\omega'=\boxed{\sqrt{\frac{1}{LC}-\left(\frac{1}{2L}\right)^2}},$$

the condition that must be satisfied if $Q=Q_0e^{-t/\tau}\cos\omega't$ is the solution to Equation 29-43*b*.

78 ••• One method for measuring the magnetic susceptibility of a sample uses an *LC* circuit consisting of an air-core solenoid and a capacitor. The resonant frequency of the circuit without the sample is determined and then measured

again with the sample inserted in the solenoid. Suppose you have a solenoid that is 4.00 cm long, 3.00 mm in diameter, and has 400 turns of fine wire. You have a sample that is inserted in the solenoid and completely fills the air space. Neglect end effects. (*a*) Calculate the inductance of your empty solenoid. (*b*) What value for the capacitance of the capacitor should you choose that the resonance frequency of the circuit without a sample is exactly 6.0000 MHz? (*c*) When a sample is inserted in the solenoid, you determine that the resonance frequency drops to 5.9989 MHz. Use your data to determine the sample's susceptibility.

Picture the Problem We can use $L=\mu_0 n^2 A\ell$ to determine the inductance of the empty solenoid and the resonance condition to find the capacitance of the sample-free circuit when the resonance frequency of the circuit is 6.0000 MHz. By expressing L as a function of f_0 and then evaluating df_0/dL and approximating the derivative with $\Delta f_0/\Delta L$, we can evaluate χ from its definition.

(*a*) Express the inductance of an air-core solenoid:

$$L=\mu_0 n^2 A\ell$$

Substitute numerical values and evaluate L:

$$L=\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(\frac{400}{4.00\,\text{cm}}\right)^2\frac{\pi}{4}(3.00\,\text{cm})^2(4.00\,\text{cm})=3.553\,\text{mH}=\boxed{3.55\,\text{mH}}$$

(*b*) Express the condition for resonance in the LC circuit:

$$X_L=X_C\Rightarrow 2\pi f_0 L=\frac{1}{2\pi f_0 C}\qquad(1)$$

Solving for C yields:

$$C=\frac{1}{4\pi^2 f_0^2 L}$$

Substitute numerical values and evaluate C:

$$C=\frac{1}{4\pi^2(6.0000\,\text{MHz})^2(3.553\,\text{mH})}=1.9803\times10^{-13}\ \text{F}=\boxed{0.198\,\text{pF}}$$

(*c*) Express the sample's susceptibility in terms of L and ΔL:

$$\chi=\frac{\Delta L}{L}\qquad(2)$$

Solve equation (1) for f_0:

$$f_0=\frac{1}{2\pi\sqrt{LC}}$$

Differentiate f_0 with respect to L:

$$\frac{df_0}{dL}=\frac{1}{2\pi\sqrt{C}}\frac{d}{dL}L^{-1/2}=-\frac{1}{4\pi\sqrt{C}}L^{-3/2}$$

$$=-\frac{1}{4\pi L\sqrt{LC}}=-\frac{f_0}{2L}$$

Approximate df_0/dL by $\Delta f_0/\Delta L$:

$$\frac{\Delta f_0}{\Delta L}=-\frac{f_0}{2L}\ \text{or}\ \frac{\Delta f_0}{f_0}=-\frac{\Delta L}{2L}$$

Substitute in equation (2) to obtain:

$$\chi=-2\frac{\Delta f_0}{f_0}$$

Substitute numerical values and evaluate χ:

$$\chi=-2\left(\frac{5.9989\,\text{MHz}-6.0000\,\text{MHz}}{6.0000\,\text{MHz}_0}\right)$$

$$=\boxed{3.7\times10^{-4}}$$

The Transformer

79 • **[SSM]** A rms voltage of 24 V is required for a device whose impedance is 12 Ω. (*a*) What should the turns ratio of a transformer be, so that the device can be operated from a 120-V line? (*b*) Suppose the transformer is accidentally connected in reverse with the secondary winding across the 120-V-rms line and the 12-Ω load across the primary. How much rms current will then be in the primary winding?

Picture the Problem Let the subscript 1 denote the primary and the subscript 2 the secondary. We can use $V_2N_1=V_1N_2$ and $N_1I_1=N_2I_2$ to find the turns ratio and the primary current when the transformer connections are reversed.

(*a*) Relate the number of primary and secondary turns to the primary and secondary voltages:

$$V_{2,\,\text{rms}}N_1=V_{1,\,\text{rms}}N_2 \qquad (1)$$

Solve for and evaluate the ratio N_2/N_1:

$$\frac{N_2}{N_1}=\frac{V_{2,\,\text{rms}}}{V_{1,\,\text{rms}}}=\frac{24\,\text{V}}{120\,\text{V}}=\boxed{\frac{1}{5}}$$

(*b*) Relate the current in the primary to the current in the secondary and to the turns ratio:

$$I_{1,\,\text{rms}}=\frac{N_2}{N_1}I_{2,\,\text{rms}}$$

Express the current in the primary winding in terms of the voltage across it and its impedance:

$$I_{2,\,\mathrm{rms}} = \frac{V_{2,\,\mathrm{rms}}}{Z_2}$$

Substitute for $I_{2,\,\mathrm{rms}}$ to obtain:

$$I_{1,\,\mathrm{rms}} = \frac{N_2}{N_1}\frac{V_{2,\,\mathrm{rms}}}{Z_2}$$

Substitute numerical values and evaluate $I_{1,\,\mathrm{rms}}$:

$$I_1 = \left(\frac{5}{1}\right)\left(\frac{120\,\mathrm{V}}{12\,\Omega}\right) = \boxed{50\,\mathrm{A}}$$

80 • A transformer has 400 turns in the primary and 8 turns in the secondary. (*a*) Is this a step-up or a step-down transformer? (*b*) If the primary is connected to a 120 V rms voltage source, what is the open-circuit rms voltage across the secondary? (*c*) If the primary rms current is 0.100 A, what is the secondary rms current, assuming negligible magnetization current and no power loss?

Picture the Problem Let the subscript 1 denote the primary and the subscript 2 the secondary. We can decide whether the transformer is a step-up or step-down transformer by examining the ratio of the number of turns in the secondary to the number of terms in the primary. We can relate the open-circuit rms voltage in the secondary to the primary rms voltage and the turns ratio.

(*a*) Because there are fewer turns in the secondary than in the primary it is a step-down transformer.

(*b*) Relate the open-circuit rms voltage $V_{2,\,\mathrm{rms}}$ in the secondary to the rms voltage $V_{1,\,\mathrm{rms}}$ in the primary:

$$V_{2,\,\mathrm{rms}} = \frac{N_2}{N_1}V_{1,\,\mathrm{rms}}$$

Substitute numerical values and evaluate $V_{2,\,\mathrm{rms}}$:

$$V_{2,\,\mathrm{rms}} = \frac{8}{400}(120\,\mathrm{V}) = \boxed{2.40\,\mathrm{V}}$$

(*c*) Because there are no power losses:

$$V_{1,\,\mathrm{rms}}I_{1,\,\mathrm{rms}} = V_{2,\,\mathrm{rms}}I_{2,\,\mathrm{rms}}$$

and

$$I_{2,\,\mathrm{rms}} = \frac{V_{1,\,\mathrm{rms}}}{V_{2,\,\mathrm{rms}}}I_{1,\,\mathrm{rms}}$$

Substitute numerical values and evaluate $I_{2,\,\mathrm{rms}}$:

$$I_{2,\,\mathrm{rms}} = \frac{120\,\mathrm{V}}{2.40\,\mathrm{V}}(0.100\,\mathrm{A}) = \boxed{5.00\,\mathrm{A}}$$

81 • The primary of a step-down transformer has 250 turns and is connected to a 120-V rms line. The secondary is to supply 20 A rms at 9.0 V rms. Find (*a*) the rms current in the primary and (*b*) the number of turns in the secondary, assuming 100 percent efficiency.

Picture the Problem Let the subscript 1 denote the primary and the subscript 2 the secondary. We can use $I_{1,\,\text{rms}}V_{1,\,\text{rms}} = I_{2,\,\text{rms}}V_{2,\,\text{rms}}$ to find the current in the primary and $V_{2,\,\text{rms}}N_1 = V_{1,\,\text{rms}}N_2$ to find the number of turns in the secondary.

(*a*) Because we have 100 percent efficiency:

$$I_{1,\,\text{rms}}V_{1,\,\text{rms}} = I_{2,\,\text{rms}}V_{2,\,\text{rms}}$$

and

$$I_{1,\,\text{rms}} = I_{2,\,\text{rms}}\frac{V_{2,\,\text{rms}}}{V_{1,\,\text{rms}}}$$

Substitute numerical values and evaluate $I_{1,\,\text{rms}}$:

$$I_{1,\,\text{rms}} = (20\,\text{A})\frac{9.0\,\text{V}}{120\,\text{V}} = \boxed{1.5\,\text{A}}$$

(*b*) Relate the number of primary and secondary turns to the primary and secondary voltages:

$$V_{2,\,\text{rms}}N_1 = V_{1,\,\text{rms}}N_2 \Rightarrow N_2 = \frac{V_{2,\,\text{rms}}}{V_{1,\,\text{rms}}}N_1$$

Substitute numerical values and evaluate N_2/N_1:

$$N_2 = \frac{9.0\,\text{V}}{120\,\text{V}}(250) \approx \boxed{19}$$

82 •• An audio oscillator (ac source) that has an internal resistance of 2000 Ω and an open-circuit rms output voltage of 12.0 V is to be used to drive a loudspeaker coil that has a resistance of 8.00 Ω. (*a*) What should be the ratio of primary to secondary turns of a transformer, so that maximum average power is transferred to the speaker? (*b*) Suppose a second identical speaker is connected in parallel with the first speaker. How much average power is then supplied to the two speakers combined?

Picture the Problem Note: In a simple circuit maximum power transfer from source to load requires that the load resistance equals the internal resistance of the source. We can use Ohm's law and the relationship between the primary and secondary currents and the primary and secondary voltages and the turns ratio of the transformer to derive an expression for the turns ratio as a function of the effective resistance of the circuit and the resistance of the speaker(s).

(*a*) Express the effective loudspeaker resistance at the primary of the transformer:

$$R_{\text{eff}} = \frac{V_{1,\,\text{rms}}}{I_{1,\,\text{rms}}}$$

Relate $V_{1,\,\text{rms}}$ to $V_{2,\,\text{rms}}$, N_1, and N_2:

$$V_{1,\,\text{rms}} = V_{2,\,\text{rms}}\frac{N_1}{N_2}$$

Express $I_{1,\,\text{rms}}$ in terms of $I_{2,\,\text{rms}}$, N_1, and N_2:

$$I_{1,\,\text{rms}} = I_{2,\,\text{rms}}\frac{N_2}{N_1}$$

Substitute for $V_{1,\,\text{rms}}$ and $I_{1,\,\text{rms}}$ and simplify to obtain:

$$R_{\text{eff}} = \frac{V_{2,\,\text{rms}}\dfrac{N_1}{N_2}}{I_{2,\,\text{rms}}\dfrac{N_2}{N_1}} = \left(\frac{V_{2,\,\text{rms}}}{I_{2,\,\text{rms}}}\right)\left(\frac{N_1}{N_2}\right)^2$$

Solve for N_1/N_2:

$$\frac{N_1}{N_2} = \sqrt{\frac{I_{2,\,\text{rms}}R_{\text{eff}}}{V_{2,\,\text{rms}}}} = \sqrt{\frac{R_{\text{eff}}}{R_2}} \qquad (1)$$

Evaluate N_1/N_2 for $R_{\text{eff}} = R_{\text{coil}}$:

$$\frac{N_1}{N_2} = \sqrt{\frac{2000\,\Omega}{8.00\,\Omega}} = 15.811 = \boxed{15.8}$$

(*b*) Express the power delivered to the two speakers connected in parallel:

$$P_{\text{sp}} = I_{1,\,\text{rms}}^2 R_{\text{eff}} \qquad (2)$$

Find the equivalent resistance R_{sp} of the two 8.00-Ω speakers in parallel:

$$\frac{1}{R_{\text{sp}}} = \frac{1}{8.00\,\Omega} + \frac{1}{8.00\,\Omega} \Rightarrow R_{\text{sp}} = 4.00\,\Omega$$

Solve equation (1) for R_{eff} to obtain:

$$R_{\text{eff}} = R_2\left(\frac{N_1}{N_2}\right)^2$$

Substitute numerical values and evaluate R_{eff}:

$$R_{\text{eff}} = (4.00\,\Omega)(15.811)^2 = 1000\,\Omega$$

Find the current supplied by the source:

$$I_{1,\,\text{rms}} = \frac{V_{\text{rms}}}{R_{\text{tot}}} = \frac{12.0\,\text{V}}{2000\,\Omega + 1000\,\Omega} = 4.00\,\text{mA}$$

Substitute numerical values in equation (2) and evaluate the power delivered to the parallel speakers:

$$P_{\text{sp}} = (4.00\,\text{mA})^2(1000\,\Omega) = \boxed{16.0\,\text{mW}}$$

General Problems

83 • The distribution circuit of a residential power line is operated at 2000 V rms. This voltage must be reduced to 240 V rms for use within residences. If the secondary side of the transformer has 400 turns, how many turns are in the primary?

Picture the Problem We can relate the input and output voltages to the number of turns in the primary and secondary using $V_{2,\,\mathrm{rms}}N_1 = V_{1,\,\mathrm{rms}}N_2$.

Relate the output voltages $V_{2,\,\mathrm{rms}}$ to the input voltage $V_{1,\,\mathrm{rms}}$ and the number of turns in the primary N_1 and secondary N_2:

$$V_{2,\,\mathrm{rms}} = \frac{N_2}{N_1}V_{1,\,\mathrm{rms}} \Rightarrow N_1 = N_2\frac{V_{1,\,\mathrm{rms}}}{V_{2,\,\mathrm{rms}}}$$

Substitute numerical values and evaluate N_1:

$$N_1 = (400)\left(\frac{2000\,\mathrm{V}}{240\,\mathrm{V}}\right) = \boxed{3.33\times10^3}$$

84 •• A resistor that has a resistance R carries a current given by (5.0 A) sin $2\pi ft$ + (7.0 A) sin $4\pi ft$, where f = 60 Hz. (*a*) What is the rms current in the resistor? (*b*) If R =12 Ω, what is the average power delivered to the resistor? (*c*) What is the rms voltage across the resistor?

Picture the Problem We can use its definition, $I_{\mathrm{rms}} = \sqrt{\left(I^2\right)_{\mathrm{av}}}$ to relate the rms current to the current carried by the resistor and find $\left(I^2\right)_{\mathrm{av}}$ by integrating I^2.

(*a*) Express the rms current in terms of the $\left(I^2\right)_{\mathrm{av}}$:

$$I_{\mathrm{rms}} = \sqrt{\left(I^2\right)_{\mathrm{av}}}$$

Evaluate I^2:

$$\begin{aligned} I^2 &= \left[(5.0\,\mathrm{A})\sin 2\pi ft + (7.0\,\mathrm{A})\sin 4\pi ft\right]^2 \\ &= \left(25\,\mathrm{A}^2\right)\sin^2 2\pi ft + \left(70\,\mathrm{A}^2\right)\sin 2\pi ft\sin 4\pi ft + \left(49\,\mathrm{A}^2\right)\sin^2 4\pi ft \end{aligned}$$

Find $\left(I^2\right)_{\mathrm{av}}$ by integrating I^2 from t = 0 to $t = T = 2\pi/\omega$ and dividing by T:

$$\begin{aligned} \left(I^2\right)_{\mathrm{av}} = \frac{\omega}{2\pi}\int_0^{2\pi/\omega} &\left\{\left(25\,\mathrm{A}^2\right)\sin^2 2\pi ft + \left(70\,\mathrm{A}^2\right)\sin 2\pi ft\sin 4\pi ft \right. \\ &\left. + \left(49\,\mathrm{A}^2\right)\sin^2 4\pi ft\right\}dt \end{aligned}$$

Use the trigonometric identity $\sin^2 x = \frac{1}{2}(1-\cos 2x)$ to simplify and evaluate the 1st and 3rd integrals and recognize that the middle term is of the form sin*x*sin2*x* to obtain:

$$\left(I^2\right)_{\text{av}} = 12.5\,\text{A}^2 + 0 + 24.5\,\text{A}^2 = 37.0\,\text{A}^2$$

Substitute for $\left(I^2\right)_{\text{av}}$ and evaluate I_{rms}:

$$I_{\text{rms}} = \sqrt{37.0\,\text{A}^2} = \boxed{6.1\,\text{A}}$$

(*b*) Relate the power dissipated in the resistor to its resistance and the rms current in it:

$$P = I_{\text{rms}}^2 R$$

Substitute numerical values and evaluate *P*:

$$P = (6.08\,\text{A})^2(12\,\Omega) = \boxed{0.44\,\text{kW}}$$

(*c*) Express the rms voltage across the resistor in terms of *R* and I_{rms}:

$$V_{\text{rms}} = I_{\text{rms}} R$$

Substitute numerical values and evaluate V_{rms}:

$$V_{\text{rms}} = (6.08\,\text{A})(12\,\Omega) = \boxed{73\,\text{V}}$$

85 •• [SSM] Figure 29-45 shows the voltage versus time for a *square-wave* voltage source. If V_0 = 12 V, (*a*) what is the rms voltage of this source? (*b*) If this alternating waveform is rectified by eliminating the negative voltages, so that only the positive voltages remain, what is the new rms voltage?

Picture the Problem The average of any quantity over a time interval Δ*T* is the integral of the quantity over the interval divided by Δ*T*. We can use this definition to find both the average of the voltage squared, $\left(V^2\right)_{\text{av}}$ and then use the definition of the rms voltage.

(*a*) From the definition of V_{rms} we have:

$$V_{\text{rms}} = \sqrt{\left(V_0^2\right)_{\text{av}}}$$

Noting that $-V_0^2 = V_0^2$, evaluate V_{rms}:

$$V_{\text{rms}} = \sqrt{V_0^2} = V_0 = \boxed{12\,\text{V}}$$

(*b*) Noting that the voltage during the second half of each cycle is now zero, express the voltage during the first half cycle of the time interval $\frac{1}{2}\Delta T$:

$$V = V_0$$

Express the square of the voltage during this half cycle:

$$V^2 = V_0^2$$

Calculate $\left(V^2\right)_{\text{av}}$ by integrating V^2 from $t = 0$ to $t = \frac{1}{2}\Delta T$ and dividing by ΔT:

$$\left(V^2\right)_{\text{av}} = \frac{V_0^2}{\Delta T}\int_0^{\frac{1}{2}\Delta T} dt = \frac{V_0^2}{\Delta T}\left[t\right]_0^{\frac{1}{2}\Delta T} = \tfrac{1}{2}V_0^2$$

Substitute to obtain:

$$V_{\text{rms}} = \sqrt{\tfrac{1}{2}V_0^2} = \frac{V_0}{\sqrt{2}} = \frac{12\text{ V}}{\sqrt{2}} = \boxed{8.5\text{ V}}$$

86 •• What are the average values and rms values of current for the two current waveforms shown in Figure 29-46?

Picture the Problem The average of any quantity over a time interval ΔT is the integral of the quantity over the interval divided by ΔT. We can use this definition to find both the average current I_{av}, and the average of the current squared, $\left(I^2\right)_{\text{av}}$

From the definition of I_{av} and I_{rms} we have:

$$I_{\text{av}} = \frac{1}{\Delta T}\int_0^{\Delta T} I dt \text{ and } I_{\text{rms}} = \sqrt{\left(I^2\right)_{\text{av}}}$$

<u>Waveform (*a*)</u> Express the current during the first half cycle of time interval ΔT:

$$I_a = \frac{4\text{ A}}{\Delta T}t$$

where I is in A when t and T are in seconds.

Evaluate $I_{\text{av},\,a}$:

$$I_{\text{av},\,a} = \frac{1}{\Delta T}\int_0^{\Delta T}\frac{4.0\text{ A}}{\Delta T}tdt = \frac{4.0\text{ A}}{(\Delta T)^2}\int_0^{\Delta T} tdt$$

$$= \frac{4.0\text{ A}}{(\Delta T)^2}\left[\frac{t^2}{2}\right]_0^{\Delta T} = \boxed{2.0\text{ A}}$$

Express the square of the current during this half cycle:

$$I_a^2 = \frac{(4.0\text{ A})^2}{(\Delta T)^2}t^2$$

Noting that the average value of the squared current is the same for each time interval ΔT, calculate $(I_a^2)_{av}$ by integrating I_a^2 from $t = 0$ to $t = \Delta T$ and dividing by ΔT:

$$(I_a^2)_{av} = \frac{1}{\Delta T}\int_0^{\Delta T}\frac{(4.0\text{ A})^2}{(\Delta T)^2}t^2 dt = \frac{(4.0\text{ A})^2}{(\Delta T)^3}\left[\frac{t^3}{3}\right]_0^{\Delta T} = \frac{16}{3}\text{A}^2$$

Substitute in the expression for $I_{\text{rms},a}$ to obtain:

$$I_{\text{rms},a} = \sqrt{\frac{16}{3}\text{A}^2} = \boxed{2.3\text{ A}}$$

Waveform (*b*) Noting that the current during the second half of each cycle is zero, express the current during the first half cycle of the time interval $\frac{1}{2}\Delta T$:

$$I_b = 4.0\text{ A}$$

Evaluate $I_{\text{av},b}$:

$$I_{\text{av},b} = \frac{4.0\text{ A}}{\Delta T}\int_0^{\frac{1}{2}\Delta T} dt = \frac{4.0\text{ A}}{\Delta T}[t]_0^{\frac{1}{2}\Delta T} = \boxed{2.0\text{ A}}$$

Express the square of the current during this half cycle:

$$I_b^2 = (4.0\text{ A})^2$$

Calculate $(I_b^2)_{av}$ by integrating I_b^2 from $t = 0$ to $t = \frac{1}{2}\Delta T$ and dividing by ΔT:

$$(I_b^2)_{av} = \frac{(4.0\text{ A})^2}{\Delta T}\int_0^{\frac{1}{2}\Delta} dt = \frac{(4.0\text{ A})^2}{\Delta T}[t]_0^{\frac{1}{2}\Delta T} = 8.0\text{ A}^2$$

Substitute in the expression for $I_{\text{rms},b}$ to obtain:

$$I_{\text{rms},b} = \sqrt{8.0\text{ A}^2} = \boxed{2.8\text{ A}}$$

87 •• In the circuit shown in Figure 29-47, $\mathcal{E}_1 = (20\text{ V})\cos 2\pi ft$, where $f = 180$ Hz; $\mathcal{E}_2 = 18$ V, and $R = 36\ \Omega$. Find the maximum, minimum, average, and rms values of the current in the resistor.

Picture the Problem We can apply Kirchhoff's loop rule to express the current in the circuit in terms of the emfs of the sources and the resistance of the resistor. We can then find $I_{\max}$ and $I_{\min}$ by considering the conditions under which the time-dependent factor in I will be a maximum or a minimum. Finally, we can use

$I_{\text{rms}} = \sqrt{(I^2)_{\text{av}}}$ to derive an expression for I_{rms} that we can use to determine its value.

Apply Kirchhoff's loop rule to obtain: $\mathcal{E}_{1,\text{peak}} \cos\omega t + \mathcal{E}_2 - IR = 0$

Solving for I yields:
$$I = \frac{\mathcal{E}_{1,\text{peak}}}{R}\cos\omega t + \frac{\mathcal{E}_2}{R}$$
or
$$I = A_1 \cos\omega t + A_2$$
where $A_1 = \dfrac{\mathcal{E}_{1,\text{peak}}}{R}$ and $A_2 = \dfrac{\mathcal{E}_2}{R}$

Substitute numerical values to obtain:
$$\begin{aligned} I &= \left(\frac{20\,\text{V}}{36\,\Omega}\right)\cos\left(2\pi\left(180\,\text{s}^{-1}\right)t\right) + \frac{18\,\text{V}}{36\,\Omega} \\ &= (0.556\,\text{A})\cos\left(1131\,\text{s}^{-1}\right)t + 0.50\,\text{A} \end{aligned}$$

The current is a maximum when $\cos\left(1131\,\text{s}^{-1}\right)t = 1$. Hence:
$$I_{\max} = 0.50\,\text{A} + 0.556\,\text{A} = \boxed{1.06\,\text{A}}$$

Evaluate $I_{\min}$:
$$I_{\min} = 0.50\,\text{A} - 0.556\,\text{A} = \boxed{-0.06\,\text{A}}$$

Because the average value of $\cos\omega t = 0$:
$$I_{\text{av}} = \boxed{0.50\,\text{A}}$$

The rms current is the square root of the average of the squared current:
$$I_{\text{rms}} = \sqrt{\left[I^2\right]_{\text{av}}} \qquad (1)$$

$\left[I^2\right]_{\text{av}}$ is given by:
$$\begin{aligned} \left[I^2\right]_{\text{av}} &= \left[(A_1 \cos\omega t + A_2)^2\right]_{\text{av}} \\ &= \left[A_1^2 \cos^2 \omega t + 2A_1A_2 \cos\omega t + A_2^2\right]_{\text{av}} \\ &= \left[A_1^2 \cos^2 \omega t\right]_{\text{av}} + \left[2A_1A_2 \cos\omega t\right]_{\text{av}} + \left[A_2^2\right]_{\text{av}} \\ &= A_1^2\left[\cos^2 \omega t\right]_{\text{av}} + 2A_1A_2\left[\cos\omega t\right]_{\text{av}} + A_2^2 \end{aligned}$$

Because $\left[\cos^2 \omega t\right]_{\text{av}} = \frac{1}{2}$ and $\left[\cos\omega t\right]_{\text{av}} = 0$:
$$\left[I^2\right]_{\text{av}} = \tfrac{1}{2}A_1^2 + A_2^2$$

Substituting in equation (1) yields:
$$I_{\text{rms}} = \sqrt{\tfrac{1}{2}A_1^2 + A_2^2}$$

Substitute for A_1 and A_2 to obtain:

$$I_{\text{rms}} = \sqrt{\tfrac{1}{2}\left(\frac{\mathcal{E}_1}{R}\right)^2 + \left(\frac{\mathcal{E}_2}{R}\right)^2}$$

Substitute numerical values and evaluate I_{rms}:

$$I_{\text{rms}} = \sqrt{\tfrac{1}{2}\left(\frac{20\text{ V}}{36\,\Omega}\right)^2 + \left(\frac{18\text{ V}}{36\,\Omega}\right)^2} = \boxed{0.64\text{ A}}$$

88 •• Repeat Problem 87 if the resistor is replaced by a 2.0-μF capacitor.

Picture the Problem We can apply Kirchhoff's loop rule to obtain an expression for charge on the capacitor as a function of time. Differentiating this expression with respect to time will give us the current in the circuit. We can then find I_{max} and I_{min} by considering the conditions under which the time-dependent factor in I will be a maximum or a minimum. Finally, we can use $I_{\text{rms}} = \sqrt{\left(I^2\right)_{\text{av}}}$ to derive an expression for I_{rms} that we can use to determine its value.

Apply Kirchhoff's loop rule to obtain:

$$\mathcal{E}_{1\,\text{peak}}\cos\omega t + \mathcal{E}_2 - \frac{q(t)}{C} = 0$$

Solving for $q(t)$ yields:

$$q(t) = C\left(\mathcal{E}_{1\,\text{peak}}\cos\omega t + \mathcal{E}_2\right) = A_1\cos\omega t + A_2$$

where

$A_1 = C\mathcal{E}_{1\,\text{peak}}$ and $A_2 = C\mathcal{E}_2$

Differentiate this expression with respect to t to obtain the current as a function of time:

$$I = \frac{dq}{dt} = \frac{d}{dt}\left(A_1\cos\omega t + A_2\right) = -\omega A_1\sin\omega t$$

Substituting numerical values yields:

$$I = -2\pi(180\text{ Hz})(2.0\;\mu\text{F})\sin\left(2\pi(180\text{ Hz})t\right) = (-2.26\text{ mA})\sin\left(1131\text{ s}^{-1}\right)t$$

The current is a minimum when $\sin\left(1131\text{s}^{-1}\right)t = 1$. Hence:

$$I_{\text{min}} = \boxed{-2.3\text{mA}}$$

The current is a maximum when $\sin\left(1131\text{s}^{-1}\right)t = -1$. Hence:

$$I_{\text{max}} = \boxed{2.3\text{mA}}$$

Because the dc source sees the capacitor as an open circuit and the average value of the sine function over a period is zero:

$$I_{av} = \boxed{0}$$

The rms current is the square root of the average of the squared current:

$$I_{rms} = \sqrt{\left[I^2\right]_{av}} \qquad (1)$$

$\left[I^2\right]_{av}$ is given by:

$$\begin{aligned}\left[I^2\right]_{av} &= \left[(A_1 \cos\omega t + A_2)^2\right]_{av}\\ &= \left[A_1^2 \cos^2 \omega t + 2A_1A_2 \cos\omega t + A_2^2\right]_{av}\\ &= \left[A_1^2 \cos^2 \omega t\right]_{av} + \left[2A_1A_2 \cos\omega t\right]_{av} + \left[A_2^2\right]_{av}\\ &= A_1^2\left[\cos^2 \omega t\right]_{av} + 2A_1A_2\left[\cos\omega t\right]_{av} + A_2^2\end{aligned}$$

Because $\left[\cos^2 \omega t\right]_{av} = \frac{1}{2}$ and $\left[\cos\omega t\right]_{av} = 0$:

$$\left[I^2\right]_{av} = \tfrac{1}{2}A_1^2 + A_2^2$$

Substituting in equation (1) yields:

$$I_{rms} = \sqrt{\tfrac{1}{2}A_1^2 + A_2^2}$$

Substitute for A_1 and A_2 to obtain:

$$\begin{aligned}I_{rms} &= \sqrt{\tfrac{1}{2}(C\mathcal{E}_1)^2 + (C\mathcal{E}_2)^2}\\ &= C\sqrt{\tfrac{1}{2}(\mathcal{E}_1)^2 + (\mathcal{E}_2)^2}\end{aligned}$$

Substitute numerical values and evaluate I_{rms}:

$$\begin{aligned}I_{rms} &= (2.0\ \mu\text{F})\sqrt{\tfrac{1}{2}(20\ \text{V})^2 + (18\ \text{V})^2}\\ &= \boxed{46\ \mu\text{A}}\end{aligned}$$

89 ••• [SSM] A circuit consists of an ac generator, a capacitor and an ideal inductor—all connected in series. The emf of the generator is given by $\mathcal{E}_{peak} \cos\omega t$. (*a*) Show that the charge on the capacitor obeys the equation $L\dfrac{d^2Q}{dt^2} + \dfrac{Q}{C} = \mathcal{E}_{peak} \cos\omega t$. (*b*) Show by direct substitution that this equation is satisfied by $Q = Q_{peak} \cos\omega t$ where $Q_{peak} = -\dfrac{\mathcal{E}_{peak}}{L\left(\omega^2 - \omega_0^2\right)}$. (*c*) Show that the current can be written as $I = I_{peak} \cos(\omega t - \delta)$, where $I_{peak} = \dfrac{\omega\mathcal{E}_{peak}}{L\left|\omega^2 - \omega_0^2\right|} = \dfrac{\mathcal{E}_{peak}}{\left|X_L - X_C\right|}$ and $\delta = -90^\circ$ for $\omega < \omega_0$ and $\delta = 90^\circ$ for $\omega > \omega_0$, where ω_0 is the resonance frequency.

Picture the Problem In Part (a) we can apply Kirchhoff's loop rule to obtain the 2nd order differential equation relating the charge on the capacitor to the time. In Part (b) we'll assume a solution of the form $Q = Q_{\text{peak}} \cos \omega t$, differentiate it twice, and substitute for d^2Q/dt^2 and Q to show that the assumed solution satisfies the differential equation provided $Q_{\text{peak}} = -\dfrac{\mathcal{E}_{\text{peak}}}{L\left(\omega^2 - \omega_0^2\right)}$. In Part ($c$) we'll use our results from (a) and (b) to establish the result for I_{peak} given in the problem statement.

(a) Apply Kirchhoff's loop rule to obtain:

$$\mathcal{E} - \frac{Q}{C} - L\frac{dI}{dt} = 0$$

Substitute for $\mathcal{E}$ and rearrange the differential equation to obtain:

$$L\frac{dI}{dt} + \frac{Q}{C} = \mathcal{E}_{\text{max}} \cos \omega t$$

Because $I = dQ/dt$:

$$\boxed{L\frac{d^2Q}{dt^2} + \frac{Q}{C} = \mathcal{E}_{\text{max}} \cos \omega t}$$

(b) Assume that the solution is:

$$Q = Q_{\text{peak}} \cos \omega t$$

Differentiate the assumed solution twice to obtain:

$$\frac{dQ}{dt} = -\omega Q_{\text{peak}} \sin \omega t$$

and

$$\frac{d^2Q}{dt^2} = -\omega^2 Q_{\text{peak}} \cos \omega t$$

Substitute for $\dfrac{dQ}{dt}$ and $\dfrac{d^2Q}{dt^2}$ in the differential equation to obtain:

$$-\omega^2 L Q_{\text{peak}} \cos \omega t + \frac{Q_{\text{peak}}}{C} \cos \omega t = \mathcal{E}_{\text{peak}} \cos \omega t$$

Factor $\cos\omega t$ from the left-hand side of the equation:

$$\left(-\omega^2 L Q_{\text{peak}} + \frac{Q_{\text{peak}}}{C}\right) \cos \omega t = \mathcal{E}_{\text{peak}} \cos \omega t$$

If this equation is to hold for all values of t it must be true that:

$$-\omega^2 L Q_{\text{peak}} + \frac{Q_{\text{peak}}}{C} = \mathcal{E}_{\text{peak}}$$

Solving for Q_{peak} yields:

$$Q_{\text{peak}} = \frac{\mathcal{E}_{\text{peak}}}{-\omega^2 L + \dfrac{1}{C}}$$

Factor L from the denominator and substitute for $1/LC$ to obtain:

$$Q_{\text{peak}} = \frac{\mathcal{E}_{\text{peak}}}{L\left(-\omega^2 + \dfrac{1}{LC}\right)} = \boxed{-\frac{\mathcal{E}_{\text{peak}}}{L\left(\omega^2 - \omega_0^2\right)}}$$

(c) From (a) and (b) we have:

$$I = \frac{dQ}{dt} = -\omega Q_{\text{peak}} \sin \omega t$$

$$= \frac{\omega \mathcal{E}_{\text{peak}}}{L\left(\omega^2 - \omega_0^2\right)} \sin \omega t = I_{\text{peak}} \sin \omega t$$

$$= \boxed{I_{\text{peak}} \cos(\omega t - \delta)}$$

where

$$I_{\text{peak}} = \boxed{\frac{\omega \mathcal{E}_{\text{peak}}}{L\left|\omega^2 - \omega_0^2\right|}} = \frac{\mathcal{E}_{\text{peak}}}{\dfrac{L}{\omega}\left|\omega^2 - \omega_0^2\right|}$$

$$= \frac{\mathcal{E}_{\text{peak}}}{\left|\omega L - \dfrac{1}{\omega C}\right|} = \boxed{\frac{\mathcal{E}_{\text{peak}}}{\left|X_L - X_C\right|}}$$

If $\omega > \omega_0$, $X_L > X_C$ and the current lags the voltage by 90° ($\delta = 90°$).

If $\omega < \omega_0$, $X_L < X_C$ and the current leads the voltage by 90°($\delta = -90°$).

Chapter 30
Maxwell's Equations and Electromagnetic Waves

Conceptual Problems

1 • **[SSM]** True or false:

(*a*) The displacement current has different units than the conduction current.
(*b*) Displacement current only exists if the electric field in the region is changing with time.
(*c*) In an oscillating *LC* circuit, no displacement current exists between the capacitor plates when the capacitor is momentarily fully charged.
(*d*) In an oscillating *LC* circuit, no displacement current exists between the capacitor plates when the capacitor is momentarily uncharged.

(*a*) False. Like those of conduction current, the units of displacement current are C/s.

(*b*) True. Because displacement current is given by $I_d = \epsilon_0\, d\phi_e/dt$, I_d is zero if $d\phi_e/dt = 0$.

(*c*) True. When the capacitor is fully charged, the electric flux is momentarily a maximum (its rate of change is zero) and, consequently, the displacement current between the plates of the capacitor is zero.

(*d*) False. I_d is zero if $d\phi_e/dt = 0$. At the moment when the capacitor is momentarily uncharged, $dE/dt \neq 0$ and so $d\phi_e/dt \neq 0$.

2 • Using SI units, show that $I_d = \epsilon_0\, d\phi_e/dt$ has units of current.

Determine the Concept We need to show that $\epsilon_0\, d\phi_e/dt$ has units of amperes. We can accomplish this by substituting the SI units of ϵ_0 and $d\phi_e/dt$ and simplifying the resulting expression.

$$\frac{\text{C}^2}{\text{N}\cdot\text{m}}\cdot\frac{\frac{\text{N}}{\text{C}}\cdot\text{m}^2}{\text{s}} = \frac{\text{C}}{\text{s}} = \boxed{\text{A}}$$

3 • **[SSM]** True or false:

(*a*) Maxwell's equations apply only to electric and magnetic fields that are constant over time.
(*b*) The electromagnetic wave equation can be derived from Maxwell's equations.

(*c*) Electromagnetic waves are transverse waves.
(*d*) The electric and magnetic fields of an electromagnetic wave in free space are in phase.

(*a*) False. Maxwell's equations apply to both time-independent and time-dependent fields.

(*b*) True. One can use Faraday's law and the modified version of Ampere's law to derive the wave equation.

(*c*) True. Both the electric and magnetic fields of an electromagnetic wave oscillate at right angles to the direction of propagation of the wave.

(*d*) True.

4 • Theorists have speculated about the existence of *magnetic monopoles*, and several experimental searches for such monopoles have occurred. Suppose magnetic monopoles were found and that the magnetic field at a distance r from a monopole of strength q_m is given by $B = (\mu_0/4\pi)q_m/r^2$. Modify the Gauss's law for magnetism equation to be consistent with such a discovery.

Determine the Concept Gauss's law for magnetism would become $\boxed{\oint_S B_n dA = \mu_0 q_{\text{m, inside}}}$ where $q_{\text{m, inside}}$ is the total magnetic charge inside the Gaussian surface. Note that Gauss's law for electricity follows from the existence of electric monopoles (charges), and the electric field due to a point charge follows from the inverse-square nature of Coulomb's law.

5 • (*a*) For each of the following pairs of electromagnetic waves, which has the higher frequency: (1) visible light or X rays, (2) green light or red light, (3) infrared waves or red light. (*b*) For each of the following pairs of electromagnetic waves, which has the longer wavelength: (1) visible light or microwaves, (2) green light or ultraviolet light, (3) gamma rays or ultraviolet light.

Determine the Concept Refer to Table 30-1 to rank order the frequencies and wavelengths of the given electromagnetic radiation.

(*a*) (1) X rays (2) green light (3) red light

(*b*) (1) microwaves (2) green light (3) ultraviolet light

6 • The detection of radio waves can be accomplished with either an electric dipole antenna or a loop antenna. True or false:

(*a*) The electric dipole antenna works according to Faraday's law.
(*b*) If a linearly polarized radio wave is approaching you head on such that its electric field oscillates vertically, to best detect this wave the normal to a loop antenna's plane should be oriented so that it points either right or left.
(*c*) If a linearly polarized radio wave is approaching you such that its electric field oscillates in a horizontal plane, to best detect this wave using an dipole antenna the antenna should be oriented vertically.

(*a*) False. A dipole antenna is oriented parallel to the electric field of an incoming wave so that the wave can induce an alternating current in the antenna.

(*b*) True. A loop antenna is oriented perpendicular to the magnetic field of an incoming wave so that the changing magnetic flux through the loop can induce a current in the loop. Orienting the loop antenna's plane so that it points either right or left satisfies this condition.

(*c*) False. The dipole antenna needs to be oriented parallel to the electric field of an incoming wave so that the wave can induce an alternating current in the antenna.

7 • A transmitter emits electromagnetic waves using an electric dipole antenna oriented vertically. (*a*) A receiver to detect these waves also uses an electric dipole antenna that is one mile from the transmitting antenna and at the same altitude. How should the receiver's electric dipole antenna be oriented for optimum signal reception? (*b*) A receiver to detect these waves uses a loop antenna that is one mile from the transmitting antenna and at the same altitude. How should the loop antenna be oriented for optimum signal reception?

Determine the Concept
(*a*) The electric dipole antenna should be oriented vertically.

(*b*) The loop antenna and the electric dipole transmitting antenna should be in the same vertical plane.

8 • Show that the expression $\vec{E}\times\vec{B}/\mu_0$ for the Poynting vector $\vec{S}$ (Equation 30-21) has units of watts per square meter (the SI units for electromagnetic wave intensity).

Determine the Concept We can that $\vec{E}\times\vec{B}/\mu_0$ has units of W/m^2 by substituting the SI units of $\vec{E}$, $\vec{B}$ and μ_0 and simplifying the resulting expression.

$$\frac{\frac{\text{N}}{\text{C}}\cdot\text{T}}{\frac{\text{T}\cdot\text{m}}{\text{A}}}=\frac{\frac{\text{N}}{\text{C}}}{\frac{\text{m}}{\text{A}}}=\frac{\text{N}}{\text{C}}\cdot\frac{\text{A}}{\text{m}}=\frac{\text{N}\cdot\text{m}}{\text{C}}\cdot\frac{\frac{\text{C}}{\text{s}}}{\text{m}^2}=\frac{\frac{\text{N}\cdot\text{m}}{\text{s}}}{\text{m}^2}=\frac{\frac{\text{J}}{\text{s}}}{\text{m}^2}=\boxed{\frac{\text{W}}{\text{m}^2}}$$

9 • [SSM] If a red light beam, a green light beam, and a violet light beam, all traveling in empty space, have the same intensity, which light beam carries more momentum? (*a*) the red light beam, (*b*) the green light beam, (*c*) the violet light beam, (*d*) They all have the same momentum. (*e*) You cannot determine which beam carries the most momentum from the data given.

Determine the Concept The momentum of an electromagnetic wave is directly proportional to its energy ($p=U/c$). Because the intensity of a wave is its energy per unit area and per unit time (the average value of its Poynting vector), waves with equal intensity have equal energy and equal momentum. $\boxed{(d)}$ is correct.

10 • If a red light plane wave, a green light plane wave, and a violet light plane wave, all traveling in empty space, have the same intensity, which wave has the largest peak electric field? (*a*) the red light wave, (*b*) the green light wave, (*c*) the violet light wave, (*d*) They all have the same peak electric field. (*e*) You cannot determine the largest peak electric field from the data given.

Determine the Concept The intensity of an electromagnetic wave is given by $I=\left|\vec{S}\right|_{\text{av}}=\dfrac{E_0B_0}{2\mu_0}$.

The intensity of an electromagnetic wave is given by:

$$I=\left|\vec{S}\right|_{\text{av}}=\frac{E_0B_0}{2\mu_0}$$

Because $E_0 = cB_0$:

$$\left|\vec{S}\right|_{\text{av}}=\frac{E_0^2}{2c\mu_0}$$

This result tells us that $\left|\vec{S}\right|_{\text{av}}\propto E_0^2$ independently of the wavelength of the electromagnetic radiation. Thus $\boxed{(d)}$ is correct.

11 • Two sinusoidal plane electromagnetic waves are identical except that wave A has a peak electric field that is three times the peak electric field of wave B. How do their intensities compare? (*a*) $I_{\text{A}}=\frac{1}{3}I_{\text{B}}$ (*b*) $I_{\text{A}}=\frac{1}{9}I_{\text{B}}$ (*c*) $I_{\text{A}}=3I_{\text{B}}$ (*d*) $I_{\text{A}}=9I_{\text{B}}$ (*e*) You cannot determine how their intensities compare from the data given.

Determine the Concept The intensity of an electromagnetic wave is given by $I=\left|\vec{S}\right|_{\text{av}}=\dfrac{E_0B_0}{2\mu_0}$.

Express the intensities of the two waves:

$$I_{\text{A}}=\frac{E_{0,\text{A}}B_{0,\text{A}}}{2\mu_0}\text{ and }I_{\text{B}}=\frac{E_{0,\text{B}}B_{0,\text{B}}}{2\mu_0}$$

Dividing the first of these equations by the second and simplifying yields:

$$\frac{I_{\text{A}}}{I_{\text{B}}}=\frac{\dfrac{E_{0,\text{A}}B_{0,\text{A}}}{2\mu_0}}{\dfrac{E_{0,\text{B}}B_{0,\text{B}}}{2\mu_0}}=\frac{E_{0,\text{A}}B_{0,\text{A}}}{E_{0,\text{B}}B_{0,\text{B}}}$$

Because wave A has a peak electric field that is three times that of wave B, the peak magnetic field of A is also three times that of wave B. Hence:

$$\frac{I_{\text{A}}}{I_{\text{B}}}=\frac{(3E_{0,\text{B}})(3B_{0,\text{B}})}{E_{0,\text{B}}B_{0,\text{B}}}=9\Rightarrow I_{\text{A}}=9I_{\text{B}}$$

$\boxed{(d)}$ is correct.

Estimation and Approximation

12 •• In *laser cooling and trapping*, the forces associated with radiation pressure are used to slow down atoms from thermal speeds of hundreds of meters per second at room temperature to speeds of a few meters per second or slower. An isolated atom will absorb only radiation of specific frequencies. If the frequency of the laser-beam radiation is tuned so that the target atoms will absorb the radiation, then the radiation is absorbed during a process called *resonant absorption*. The cross-sectional area of the atom for resonant absorption is approximately equal to λ^2, where λ is the wavelength of the laser light. (*a*) Estimate the acceleration of a rubidium atom (molar mass 85 g/mol) in a laser beam whose wavelength is 780 nm and intensity is 10 W/m^2. (*b*) About how long would it take such a light beam to slow a rubidium atom in a gas at room temperature (300 K) to near-zero speed?

Picture the Problem We can use Newton's second law to express the acceleration of an atom in terms of the net force acting on the atom and the relationship between radiation pressure and the intensity of the beam to find the net force. Once we know the acceleration of an atom, we can use the definition of acceleration to find the stopping time for a rubidium atom at room temperature.

(*a*) Apply Newton's second law to the atom to obtain:

$$F_{\text{r}}=ma \qquad (1)$$

where F_{r} is the radiation force exerted by the laser beam.

The radiation pressure P_r and intensity of the beam I are related according to:

$$P_r = \frac{F_r}{A} = \frac{I}{c}$$

Solve for F_r to obtain:

$$F_r = \frac{IA}{c} = \frac{I\lambda^2}{c}$$

Substitute for F_r in equation (1) to obtain:

$$\frac{I\lambda^2}{c} = ma \Rightarrow a = \frac{I\lambda^2}{mc}$$

Substitute numerical values and evaluate a:

$$a = \frac{\left(10\,\text{W/m}^2\right)\left(780\,\text{nm}\right)^2}{\left(85\frac{\text{g}}{\text{mol}} \times \frac{1\,\text{mol}}{6.022\times10^{23}\,\text{particles}}\right)\left(2.998\times10^8\,\text{m/s}\right)} = 1.44\times10^5\,\text{m/s}^2$$
$$= \boxed{1.4\times10^5\,\text{m/s}^2}$$

(*b*) Using the definition of acceleration, express the stopping time Δt of the atom:

$$\Delta t = \frac{v_{\text{final}} - v_{\text{initial}}}{a}$$

Because $v_{\text{final}} \approx 0$:

$$\Delta t \approx \frac{-v_{\text{initial}}}{a}$$

Using the rms speed as the initial speed of an atom, relate v_{initial} to the temperature of the gas:

$$v_{\text{initial}} = v_{\text{rms}} = \sqrt{\frac{3kT}{m}}$$

Substitute in the expression for the stopping time to obtain:

$$\Delta t = -\frac{1}{a}\sqrt{\frac{3kT}{m}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = -\frac{1}{-1.44\times10^5\,\text{m/s}^2}\sqrt{\frac{3\left(1.38\times10^{-23}\,\text{J/K}\right)\left(300\,\text{K}\right)}{\left(85\frac{\text{g}}{\text{mol}} \times \frac{1\,\text{mol}}{6.022\times10^{23}\,\text{particles}}\right)}} = \boxed{2.1\,\text{ms}}$$

13 •• **[SSM]** One of the first successful satellites launched by the United States in the 1950s was essentially a large spherical (aluminized) Mylar balloon from which radio signals were reflected. After several orbits around Earth,

scientists noticed that the orbit itself was changing with time. They eventually determined that radiation pressure from the sunlight was causing the orbit of this object to change—a phenomenon not taken into account in planning the mission. Estimate the ratio of the radiation-pressure force by the sunlight on the satellite to the gravitational force by Earth's gravity on the satellite.

Picture the Problem We can use the definition of pressure to express the radiation force on the balloon. We'll assume that the gravitational force on the balloon is approximately its weight at the surface of Earth, that the density of Mylar is approximately that of water and that the area receiving the radiation from the sunlight is the cross-sectional area of the balloon.

The radiation force acting on the balloon is given by:

$$F_r = P_r A$$

where A is the cross-sectional area of the balloon.

Because the radiation from the Sun is reflected, the radiation pressure is twice what it would be if it were absorbed:

$$P_r = \frac{2I}{c}$$

Substituting for P_r and A yields:

$$F_r = \frac{2I\left(\frac{1}{4}\pi d^2\right)}{c} = \frac{\pi d^2 I}{2c}$$

The gravitational force acting on the balloon when it is in a near-Earth orbit is approximately its weight at the surface of Earth:

$$F_g = w_{\text{balloon}} = m_{\text{balloon}}g = \rho_{\text{Mylar}}V_{\text{Mylar}}g$$
$$= \rho_{\text{Mylar}}A_{\text{surface, ballon}}t\,g$$

where t is the thickness of the Mylar skin of the balloon.

Because the surface area of the balloon is $4\pi r^2 = \pi d^2$:

$$F_g = \pi\rho_{\text{Mylar}}d^2 t\,g$$

Express the ratio of the radiation-pressure force to the gravitational force and simplify to obtain:

$$\frac{F_r}{F_g} = \frac{\frac{\pi d^2 I}{2c}}{\pi\rho_{\text{Mylar}}d^2 t\,g} = \frac{I}{2\rho_{\text{Mylar}}t\,gc}$$

Assuming the thickness of the Mylar skin of the balloon to be 1 mm, substitute numerical values and evaluate F_r/F_g:

$$\frac{F_r}{F_g}=\frac{1.35\,\frac{\text{kW}}{\text{m}^2}}{2\left(1.00\times10^3\,\frac{\text{kg}}{\text{m}^3}\right)\left(9.81\,\frac{\text{m}}{\text{s}^2}\right)(1\text{ mm})\left(2.998\times10^8\,\frac{\text{m}}{\text{s}}\right)}\approx\boxed{2\times10^{-7}}$$

14 •• Some science fiction writers have described solar sails that could propel interstellar spaceships. Imagine a giant sail on a spacecraft subjected to radiation pressure from our Sun. (*a*) Explain why this arrangement works better if the sail is highly reflective rather than highly absorptive. (*b*) If the sail is assumed highly reflective, show that the force exerted by the sunlight on the spacecraft is given by $P_S A/(2\pi r^2 c)$ where P_S is the power output of the Sun (3.8×10^{26} W), A is the surface area of the sail, m is the total mass of the spacecraft, r is the distance from the Sun, and c is the speed of light. (Assume the area of the sail is much larger than the area of the spacecraft so that all the force is due to radiation pressure on the sail only.) (*c*) Using a reasonable value for A, compare the force on the spacecraft due to the radiation pressure and the force on the spacecraft due to the gravitational pull of the Sun. Does the result imply that such a system will work? Explain your answer.

Picture the Problem (*b*) We can use the definition of radiation pressure to show that the force exerted by the sunlight on the spacecraft is given by $P_S A/(2\pi r^2 c)$ where P_S is the power output of the Sun (3.8×10^{26} W), A is the surface area of the sail, m is the total mass of the spacecraft, r is the distance from the Sun, and c is the speed of light.

(*a*) If the sail is highly reflective rather than highly absorptive, the radiation force is doubled.

(*b*) Because the sail is highly reflective:

$$F_r=P_r A=\frac{2IA}{c}$$

where A is the area of the sail.

The intensity of the solar radiation on the sail is given by $I=\frac{P_s}{4\pi r^2}$.

Substituting for I yields:

$$F_r=\frac{2P_s A}{4\pi r^2 c}=\boxed{\frac{P_s A}{2\pi r^2 c}}$$

(*c*) Express the ratio of the force on the spacecraft due to the radiation pressure and the force on the spacecraft due the gravitational force of the Sun on the spacecraft:

$$\frac{F_r}{F_g}=\frac{\dfrac{P_S A}{2\pi r^2 c}}{\dfrac{GmM_S}{r^2}}=\frac{P_S A}{2\pi cGmM_S}$$

Assuming a 15-m diameter circular sail and a 500-kg spacecraft (values found using the internet), substitute numerical values and evaluate the ratio of the accelerations:

$$\frac{F_r}{F_g}=\frac{\left(3.8\times10^{26}\ \text{W}\right)\left(\dfrac{\pi}{4}(15\ \text{m})^2\right)}{2\pi\left(2.998\times10^{8}\ \dfrac{\text{m}}{\text{s}}\right)\left(6.673\times10^{-11}\ \dfrac{\text{N}\cdot\text{m}^2}{\text{kg}^2}\right)(500\ \text{kg})\left(1.99\times10^{30}\ \text{kg}\right)}$$
$$=\boxed{5.4\times10^{-4}}$$

for A = 177 m^2 and m = 500 kg**.**

This scheme is not likely to work effectively. For any reasonable spacecraft mass, the surface mass density of the sail would to be extremely small (experimental sails have area densities of approximately 3 g/m^2) and the sail would have to be huge. Additionally, unless struts are built into the sail, it would collapse during use.

Maxwell's Displacement Current

15 • [SSM] A parallel-plate capacitor has circular plates and no dielectric between the plates. Each plate has a radius equal to 2.3 cm and the plates are separated by 1.1 mm. Charge is flowing onto the upper plate (and off of the lower plate) at a rate of 5.0 A. (*a*) Find the rate of change of the electric field strength in the region between the plates. (*b*) Compute the displacement current in the region between the plates and show that it equals 5.0 A.

Picture the Problem We can differentiate the expression for the electric field between the plates of a parallel-plate capacitor to find the rate of change of the electric field strength and the definitions of the conduction current and electric flux to compute I_d.

(*a*) Express the electric field strength between the plates of the parallel-plate capacitor:

$$E=\frac{Q}{\epsilon_0 A}$$

Differentiate this expression with respect to time to obtain an expression for the rate of change of the electric field strength:

$$\frac{dE}{dt}=\frac{d}{dt}\left[\frac{Q}{\epsilon_0 A}\right]=\frac{1}{\epsilon_0 A}\frac{dQ}{dt}=\frac{I}{\epsilon_0 A}$$

Substitute numerical values and evaluate dE/dt:

$$\frac{dE}{dt}=\frac{5.0\,\text{A}}{\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\pi\left(0.023\,\text{m}\right)^2}=3.40\times10^{14}\,\text{V/m}\cdot\text{s}$$
$$=\boxed{3.4\times10^{14}\,\text{V/m}\cdot\text{s}}$$

(*b*) Express the displacement current I_d:

$$I_d=\epsilon_0\frac{d\phi_e}{dt}$$

Substitute for the electric flux to obtain:

$$I_d=\epsilon_0\frac{d}{dt}[EA]=\epsilon_0 A\frac{dE}{dt}$$

Substitute numerical values and evaluate I_d:

$$I_d=\left(8.854\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\pi\left(0.023\,\text{m}\right)^2\left(3.40\times10^{14}\,\text{V/m}\cdot\text{s}\right)=\boxed{5.0\,\text{A}}$$

16 • In a region of space, the electric field varies with time as E = (0.050 N/C) sin (ωt), where ω = 2000 rad/s. Find the peak displacement current through a surface that is perpendicular to the electric field and has an area equal to 1.00 m^2.

Picture the Problem We can express the displacement current in terms of the electric flux and differentiate the resulting expression to obtain I_d in terms of dE/dt.

The displacement current I_d is given by:

$$I_d=\epsilon_0\frac{d\phi_e}{dt}$$

Substitute for the electric flux to obtain:

$$I_d=\epsilon_0\frac{d}{dt}[EA]=\epsilon_0 A\frac{dE}{dt}$$

Because $E=\left(0.050\,\text{N/C}\right)\sin 2000t$:

$$I_d=\epsilon_0 A\frac{d}{dt}\left[\left(0.050\,\text{N/C}\right)\sin 2000t\right]$$
$$=\left(2000\,\text{s}^{-1}\right)\epsilon_0 A\left(0.050\,\text{N/C}\right)\cos 2000t$$

I_d will have its maximum value when cos 2000t = 1. Hence:

$$I_{d,max} = \left(2000\,s^{-1}\right)\in_0 A\left(0.050\,N/C\right)$$

Substitute numerical values and evaluate $I_{d,max}$:

$$I_{d,\,max} = \left(2000\,s^{-1}\right)\left(8.854\times10^{-12}\,\frac{C^2}{N\cdot m^2}\right)\left(1.00\,m^2\right)\left(0.050\,\frac{N}{C}\right) = \boxed{0.89\,nA}$$

17 • For Problem 15, show that the magnetic field strength between the plates a distance r from the axis through the centers of both plates is given by $B = (1.9 \times 10^{-3}$ T/m$)r$.

Picture the Problem We can use Ampere's law to a circular path of radius r between the plates and parallel to their surfaces to obtain an expression relating B to the current enclosed by the amperian loop. Assuming that the displacement current is uniformly distributed between the plates, we can relate the displacement current enclosed by the circular loop to the conduction current I.

Apply Ampere's law to a circular path of radius r between the plates and parallel to their surfaces to obtain:

$$\oint_C \vec{B}\cdot d\vec{\ell} = 2\pi rB = \mu_0 I_{\text{enclosed}} = \mu_0 I$$

Assuming that the displacement current is uniformly distributed:

$$\frac{I}{\pi r^2} = \frac{I_d}{\pi R^2} \Rightarrow I = \frac{r^2}{R^2}I_d$$

where R is the radius of the circular plates.

Substituting for I yields:

$$2\pi rB = \frac{\mu_0 r^2}{R^2}I_d \Rightarrow B = \frac{\mu_0 r}{2\pi R^2}I_d$$

Substitute numerical values and evaluate B:

$$B(r) = \frac{\left(4\pi\times10^{-7}\,N/A^2\right)\left(5.0\,A\right)}{2\pi\left(0.023\,m\right)^2}r$$

$$= \boxed{\left(1.9\times10^{-3}\,\frac{T}{m}\right)r}$$

18 •• The capacitors referred to in this problem have only empty space between the plates. (a) Show that a parallel-plate capacitor has a displacement current in the region between its plates that is given by $I_d = C\,dV/dt$, where C is the capacitance and V is the potential difference between the plates. (b) A 5.00-nF

parallel-plate capacitor is connected to an ideal ac generator so the potential difference between the plates is given by $V = V_0 \cos \omega t$, where $V_0 = 3.00$ V and $\omega = 500\pi$ rad/s. Find the displacement current in the region between the plates as a function of time.

Picture the Problem We can use the definitions of the displacement current and electric flux, together with the expression for the capacitance of an air-core-parallel-plate capacitor to show that $I_d = C\,dV/dt$.

(*a*) Use its definition to express the displacement current I_d:

$$I_d = \epsilon_0 \frac{d\phi_e}{dt}$$

Substitute for the electric flux to obtain:

$$I_d = \epsilon_0 \frac{d}{dt}[EA] = \epsilon_0 A \frac{dE}{dt}$$

Because $E = V/d$:

$$I_d = \epsilon_0 A \frac{d}{dt}\left[\frac{V}{d}\right] = \frac{\epsilon_0 A}{d}\frac{dV}{dt}$$

The capacitance of an air-core-parallel-plate capacitor whose plates have area A and that are separated by a distance d is given by:

$$C = \frac{\epsilon_0 A}{d}$$

Substituting yields:

$$I_d = \boxed{C\frac{dV}{dt}}$$

(*b*) Substitute in the expression derived in (*a*) to obtain:

$$I_d = (5.00\,\text{nF})\frac{d}{dt}[(3.00\,\text{V})\cos 500\pi t] = -(5.00\,\text{nF})(3.00\,\text{V})(500\pi\,\text{s}^{-1})\sin 500\pi t$$
$$= \boxed{-(23.6\,\mu\text{A})\sin 500\pi t}$$

19 •• [SSM] There is a current of 10 A in a resistor that is connected in series with a parallel plate capacitor. The plates of the capacitor have an area of 0.50 m^2, and no dielectric exists between the plates. (*a*) What is the displacement current between the plates? (*b*) What is the rate of change of the electric field strength between the plates? (*c*) Find the value of the line integral $\oint_C \vec{B}\cdot d\vec{\ell}$, where the integration path C is a 10-cm-radius circle that lies in a plane that is parallel with the plates and is completely within the region between them.

Picture the Problem We can use the conservation of charge to find I_d, the definitions of the displacement current and electric flux to find dE/dt, and Ampere's law to evaluate $\vec{B}\cdot d\vec{\ell}$ around the given path.

(*a*) From conservation of charge we know that:

$$I_d = I = \boxed{10\,\text{A}}$$

(*b*) Express the displacement current I_d:

$$I_d = \epsilon_0 \frac{d\phi_e}{dt} = \epsilon_0 \frac{d}{dt}[EA] = \epsilon_0 A \frac{dE}{dt}$$

Substituting for dE/dt yields:

$$\frac{dE}{dt} = \frac{I_d}{\epsilon_0 A}$$

Substitute numerical values and evaluate dE/dt:

$$\frac{dE}{dt} = \frac{10\,\text{A}}{\left(8.85\times10^{-12}\,\frac{\text{C}^2}{\text{N}\cdot\text{m}^2}\right)\left(0.50\,\text{m}^2\right)} = \boxed{2.3\times10^{12}\,\frac{\text{V}}{\text{m}\cdot\text{s}}}$$

(*c*) Apply Ampere's law to a circular path of radius *r* between the plates and parallel to their surfaces to obtain:

$$\oint_C \vec{B}\cdot d\vec{\ell} = \mu_0 I_{\text{enclosed}}$$

Assuming that the displacement current is uniformly distributed and letting *A* represent the area of the circular plates yields:

$$\frac{I_{\text{enclosed}}}{\pi r^2} = \frac{I_d}{A} \Rightarrow I_{\text{enclosed}} = \frac{\pi r^2}{A} I_d$$

Substitute for I_{enclosed} to obtain:

$$\oint_C \vec{B}\cdot d\vec{\ell} = \frac{\mu_0 \pi r^2}{A} I_d$$

Substitute numerical values and evaluate $\oint_C \vec{B}\cdot d\vec{\ell}$:

$$\oint_C \vec{B}\cdot d\vec{\ell} = \frac{\left(4\pi\times10^{-7}\,\text{N/A}^2\right)\pi\left(0.10\,\text{m}\right)^2\left(10\,\text{A}\right)}{0.50\,\text{m}^2} = \boxed{0.79\,\mu\text{T}\cdot\text{m}}$$

20 ••• Demonstrate the validity of the generalized form of Ampère's law (Equation 30-4) by showing that it gives the same result as the Biot–Savart law (Equation 27-3) in a specified situation. Figure 30-13 shows two momentarily

equal but opposite point charges ($+Q$ and $-Q$) on the x axis at $x = -a$ and $x = +a$, respectively. At the same instant there is a current I in the wire connecting them, as shown. Point P is on the y axis at $y = R$. (*a*) Use the Biot–Savart law to show that the magnitude of the magnetic field at point P is given by $B = \dfrac{\mu_0 Ia}{2\pi R}\dfrac{1}{\sqrt{R^2+a^2}}$. (*b*) Now consider a circular strip of radius r and width dr in the $x = 0$ plane that has its center at the origin. Show that the flux of the electric field through this strip is given by $E_x dA = \dfrac{Q\pi r}{\epsilon_0}\left(r^2+a^2\right)^{3/2} dr$. (*c*) Use the result from Part (*b*) to show that the total electric flux ϕ_e through a circular surface S of radius R. is given by $\phi_e = \dfrac{Q}{\epsilon_0}\left(1-\dfrac{a}{\sqrt{a^2+R^2}}\right)$. (*d*) Find the displacement current I_d through S, and show that $I + I_d = I\dfrac{a}{\sqrt{a^2+R^2}}$ (*e*) Finally, show that the generalized form of Ampere's law (Equation 30-4) gives the same result for the magnitude of the magnetic field as found in Part (*a*).

Picture the Problem We can follow the step-by-step instructions in the problem statement to show that Equation 30-4 gives the same result for B as that given in Part (*a*).

(*a*) Express the magnetic field strength at P using the expression for B due to a straight wire segment:

$$B_P = \frac{\mu_0}{4\pi}\frac{I}{R}\left(\sin\theta_1 + \sin\theta_2\right)$$

where

$$\sin\theta_1 = \sin\theta_2 = \frac{a}{\sqrt{R^2+a^2}}$$

Substitute for $\sin\theta_1$ and $\sin\theta_2$ to obtain:

$$B_P = \frac{\mu_0}{4\pi}\frac{I}{R}\frac{2a}{\sqrt{R^2+a^2}} = \boxed{\frac{\mu_0 Ia}{2\pi R}\frac{1}{\sqrt{R^2+a^2}}}$$

(*b*) Express the electric flux through the circular strip of radius r and width dr in the yz plane:

$$d\phi_e = E_x dA = E_x\left(2\pi r dr\right)$$

The electric field due to the dipole is:

$$E_x = \frac{2kQ}{r^2+a^2}\cos\theta_1 = \frac{2kQa}{\left(r^2+a^2\right)^{3/2}}$$

Substitute for E_x to obtain:

$$d\phi_e = E_x dA = \frac{2kQa}{\left(r^2+a^2\right)^{3/2}}\left(2\pi\, rdr\right) = \frac{2Qa}{4\pi \in_0 \left(r^2+a^2\right)^{3/2}}\left(2\pi\, rdr\right) = \boxed{\frac{Qa}{\in_0 \left(r^2+a^2\right)^{3/2}} rdr}$$

(*c*) Multiply both sides of the expression for $d\phi_e$ by $\in_0$:

$$\in_0 d\phi_e = \frac{Qa}{\left(r^2+a^2\right)^{3/2}} rdr$$

Integrate r from 0 to R to obtain:

$$\in_0 \phi_e = Qa\int_0^R \frac{rdr}{\left(r^2+a^2\right)^{3/2}} = Qa\left(\frac{-1}{\sqrt{R^2+a^2}}+\frac{1}{a}\right) = \boxed{Q\left(1-\frac{a}{\sqrt{R^2+a^2}}\right)}$$

(*d*) The displacement current is defined to be:

$$I_d = \in_0 \frac{d\phi_e}{dt} = \frac{d}{dt}\left[Q\left(1-\frac{a}{\sqrt{R^2+a^2}}\right)\right] = \left(1-\frac{a}{\sqrt{R^2+a^2}}\right)\frac{dQ}{dt} = -I\left(1-\frac{a}{\sqrt{R^2+a^2}}\right)$$

The total current is the sum of I and I_d:

$$I + I_d = I - I\left(1-\frac{a}{\sqrt{R^2+a^2}}\right) = \boxed{I\frac{a}{\sqrt{R^2+a^2}}}$$

(*e*) Apply Equation 30-4 (the generalized form of Ampere's law) to obtain:

$$\oint_C \vec{B}\cdot d\vec{\ell} = 2\pi RB = \mu_0\left(I+I_d\right)$$

Solving for B yields:

$$B = \frac{\mu_0}{2\pi R}\left(I+I_d\right)$$

Substitute for $I + I_d$ from (*d*) to obtain:

$$B = \frac{\mu_0}{2\pi R}\left(I\frac{a}{\sqrt{R^2+a^2}}\right) = \boxed{\frac{\mu_0 Ia}{2\pi R}\frac{1}{\sqrt{R^2+a^2}}}$$

Maxwell's Equations and the Electromagnetic Spectrum

21 • The color of the dominant light from the Sun is in the yellow-green region of the visible spectrum. Estimate the wavelength and frequency of the dominant light emitted by our Sun. *HINT: See Table 30-1.*

Picture the Problem We can find both the wavelength and frequency of the dominant light emitted by our Sun in Table 30-1.

Because the radiation from the Sun is yellow-green dominant, the dominant wavelength is approximately:

$$\lambda_{\text{yellow-green}} = \boxed{580\text{ nm}}$$

The corresponding frequency is:

$$f_{\text{yellow-green}} = \frac{c}{\lambda_{\text{yellow-green}}} = \frac{2.998\times10^8\text{ m/s}}{580\text{ nm}} = \boxed{5.17\times10^{14}\text{ Hz}}$$

22 • (*a*) What is the frequency of microwave radiation that has a 3.00-cm-long wavelength? (*b*) Using Table 30-1, estimate the ratio of the shortest wavelength of green light to the shortest wavelength of red light.

Picture the Problem We can use $c = f\lambda$ to find the frequency corresponding to the given wavelength.

(*a*) The frequency of an electromagnetic wave is the ratio of the speed of light in a vacuum to the wavelength of the wave:

$$f = \frac{c}{\lambda}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{2.998\times10^8\text{ m/s}}{3.00\times10^{-2}\text{ m}} = 9.993\times10^{10}\text{ Hz} = \boxed{9.99\text{GHz}}$$

(*b*) The ratio of the shortest wavelength green light to the shortest wavelength red light is:

$$\frac{\lambda_{\text{shortest green}}}{\lambda_{\text{shortest red}}} \approx \frac{520\text{ nm}}{620\text{ nm}} = \boxed{0.84}$$

23 • (*a*) What is the frequency of an X ray that has a 0.100-nm-long wavelength? (*b*) The human eye is sensitive to light that has a wavelength equal to 550 nm. What is the color and frequency of this light? Comment on how this answer compares to your answer for Problem 21.

Picture the Problem We can use $c = f\lambda$ to find the frequency corresponding to the given wavelengths and consult Table 30-1 to determine the color of light with a wavelength of 550 nm.

(*a*) The frequency of an X ray with a wavelength of 0.100 nm is:

$$f = \frac{c}{\lambda} = \frac{2.998\times10^{8}\text{ m/s}}{0.100\times10^{-9}\text{ m}}$$
$$= \boxed{3.00\times10^{18}\text{ Hz}}$$

(*b*) The frequency of light with a wavelength of 550 nm is:

$$f = \frac{2.998\times10^{8}\text{ m/s}}{550\text{nm}} = \boxed{5.45\times10^{14}\text{ Hz}}$$

Consulting Table 30-1, we see that the color of light that has a wavelength of 550 nm is yellow-green. This result is consistent with those of Problem 21 and is close to the wavelength of the peak output of the Sun. Because we see naturally by reflected sunlight, this result is not surprising.

Electric Dipole Radiation

24 •• Suppose a radiating electric dipole lies along the *z* axis. Let I_1 be the intensity of the radiation at a distance of 10 m and at angle of 90º. Find the intensity (in terms of I_1) at (*a*) a distance of 30 m and an angle of 90º, (*b*) a distance of 10 m and an angle of 45º, and (*c*) a distance of 20 m and an angle of 30º.

Picture the Problem We can use the intensity I_1 at a distance $r = 10$ m and at an angle $\theta = 90°$ to find the constant in the expression for the intensity of radiation from an electric dipole and then use the resulting equation to find the intensity at the given distances and angles.

Express the intensity of radiation as a function of *r* and θ:

$$I(\theta, r) = \frac{C}{r^2}\sin^2\theta \qquad (1)$$

where C is a constant.

Express $I(90°,10\text{ m})$:

$$I(90°,10\,\text{m}) = I_1 = \frac{C}{(10\,\text{m})^2}\sin^2 90° = \frac{C}{100\,\text{m}^2}$$

Solving for C yields:

$$C = (100\,\text{m}^2)I_1$$

Substitute in equation (1) to obtain:

$$I(\theta,r) = \frac{(100\,\text{m}^2)I_1}{r^2}\sin^2\theta \qquad (2)$$

(*a*) Evaluate equation (2) for $r = 30$ m and $\theta = 90°$:

$$I(90°,30\,\text{m}) = \frac{(100\,\text{m}^2)I_1}{(30\,\text{m})^2}\sin^2 90° = \boxed{\tfrac{1}{9}I_1}$$

(*b*) Evaluate equation (2) for $r = 10$ m and $\theta = 45°$:

$$I(45°,10\,\text{m}) = \frac{(100\,\text{m}^2)I_1}{(10\,\text{m})^2}\sin^2 45° = \boxed{\tfrac{1}{2}I_1}$$

(*c*) Evaluate equation (2) for $r = 20$ m and $\theta = 30°$:

$$I(30°,20\,\text{m}) = \frac{(100\,\text{m}^2)I_1}{(20\,\text{m})^2}\sin^2 30° = \boxed{\tfrac{1}{16}I_1}$$

25 •• (*a*) For the situation described in Problem 24, at what angle is the intensity at a distance of 5.0 m equal to I_1? (*b*) At what distance is the intensity equal to I_1 when $\theta = 45°$?

Picture the Problem We can use the intensity I_1 at a distance $r = 10$ m and at an angle $\theta = 90°$ to find the constant in the expression for the intensity of radiation from an electric dipole and then use the resulting equation to find the angle for a given intensity and distance and the distance corresponding to a given intensity and angle.

Express the intensity of radiation as a function of r and θ:

$$I(\theta,r) = \frac{C}{r^2}\sin^2\theta \qquad (1)$$

where C is a constant.

Express $I(90°,10\text{ m})$:

$$I(90°,10\,\text{m}) = I_1 = \frac{C}{(10\,\text{m})^2}\sin^2 90° = \frac{C}{100\,\text{m}^2}$$

Solving for C yields:

$$C = (100\,\text{m}^2)I_1$$

Substitute in equation (1) to obtain:

$$I(\theta,r) = \frac{(100\,\text{m}^2)I_1}{r^2}\sin^2\theta \qquad (2)$$

(*a*) For $r = 5$ m and $I(\theta,r) = I_1$:

$$I_1 = \frac{(100\,\text{m}^2)I_1}{(5.0\,\text{m})^2}\sin^2\theta \Rightarrow \sin^2\theta = \tfrac{1}{4}$$

Solve for θ to obtain:

$$\theta = \sin^{-1}\left(\tfrac{1}{2}\right) = \boxed{30°}$$

(*b*) For $\theta = 45°$ and $I(\theta,r) = I_1$:

$$I_1 = \frac{(100\,\text{m}^2)I_1}{r^2}\sin^2 45°$$

or

$$r^2 = \tfrac{1}{2}(100\,\text{m}^2)$$

Solve for r to obtain:

$$r = \sqrt{\tfrac{1}{2}(100\,\text{m}^2)} = \boxed{7.1\,\text{m}}$$

26 •• You and your engineering crew are in charge of setting up a wireless telephone network for a village in a mountainous region. The transmitting antenna of one station is an electric dipole antenna located atop a mountain 2.00 km above sea level. There is a nearby mountain that is 4.00 km from the antenna and is also 2.00 km above sea level. At that location, one member of the crew measures the intensity of the signal to be $4.00 \times 10^{-12}\ \text{W/m}^2$. What should be the intensity of the signal at the village that is located at sea level and 1.50 km from the transmitter?

Picture the Problem We can use the intensity I at a distance $r = 4.00$ km and at an angle $\theta = 90°$ to find the constant in the expression for the intensity of radiation from an electric dipole and then use the resulting equation to find the intensity at sea level and 1.50 km from the transmitter.

Express the intensity of radiation as a function of r and θ:

$$I(\theta,r) = \frac{C}{r^2}\sin^2\theta \qquad (1)$$

where C is a constant.

Use the given data to obtain:

$$4\times10^{-12}\ \text{W/m}^2 = \frac{C}{(4.00\,\text{km})^2}\sin^2 90° = \frac{C}{(4.00\,\text{km})^2}$$

Solving for C yields:

$$C = (4.00\,\text{km})^2\left(4.00\times10^{-12}\ \text{W/m}^2\right) = 6.40\times10^{-5}\ \text{W}$$

Substitute in equation (1) to obtain:

$$I(\theta,r) = \frac{6.40\times10^{-5}\ \text{W}}{r^2}\sin^2\theta \quad (2)$$

For a point at sea level and 1.50 km from the transmitter:

$$\theta = \tan^{-1}\left(\frac{2.00\,\text{km}}{1.50\,\text{km}}\right) = 53.1°$$

Evaluate I(53.1°,1.50 km):

$$I(53.1°,1.5\,\text{km}) = \frac{6.40\times10^{-5}\ \text{W}}{(1.50\,\text{km})^2}\sin^2 53.1° = \boxed{18.2\,\text{pW/m}^2}$$

27 ••• [SSM] A radio station that uses a vertical electric dipole antenna broadcasts at a frequency of 1.20 MHz and has a total power output of 500 kW. Calculate the intensity of the signal at a horizontal distance of 120 km from the station.

Picture the Problem The intensity of radiation from an electric dipole is given by $C(\sin^2\theta)/r^2$, where C is a constant whose units are those of power, r is the distance from the dipole to the point of interest, and θ is the angle between the antenna and the position vector $\vec{r}$. We can integrate the intensity to express the total power radiated by the antenna and use this result to evaluate C. Knowing C we can find the intensity at a horizontal distance of 120 km.

Express the intensity of the signal as a function of r and θ:

$$I(r,\theta) = C\frac{\sin^2\theta}{r^2}$$

At a horizontal distance of 120 km from the station:

$$I(120\,\text{km},90°) = C\frac{\sin^2 90°}{(120\,\text{km})^2} = \frac{C}{(120\,\text{km})^2} \quad (1)$$

From the definition of intensity we have:

$$dP = IdA$$

and

$$P_{\text{tot}} = \iint I(r,\theta)\,dA$$

where, in polar coordinates,

$$dA = r^2 \sin\theta\, d\theta\, d\phi$$

Substitute for dA to obtain:

$$P_{\text{tot}} = \int_0^{2\pi}\int_0^{\pi} I(r,\theta) r^2 \sin\theta\, d\theta\, d\phi$$

Substitute for $I(r,\theta)$:

$$P_{\text{tot}} = C\int_0^{2\pi}\int_0^{\pi} \sin^3\theta\, d\theta\, d\phi$$

From integral tables we find that:

$$\int_0^{\pi} \sin^3\theta d\theta = -\tfrac{1}{3}\cos\theta\left(\sin^2\theta + 2\right)\Big]_0^{\pi} = \frac{4}{3}$$

Substitute and integrate with respect to ϕ to obtain:

$$P_{\text{tot}} = \frac{4}{3}C\int_0^{2\pi} d\phi = \frac{4}{3}C[\phi]_0^{2\pi} = \frac{8\pi}{3}C$$

Solving for C yields:

$$C = \frac{3}{8\pi}P_{\text{tot}}$$

Substitute for P_{tot} and evaluate C to obtain:

$$C = \frac{3}{8\pi}(500\,\text{kW}) = 59.68\,\text{kW}$$

Substituting for C in equation (1) and evaluating I(120 km, 90°):

$$I(120\,\text{km}, 90°) = \frac{59.68\,\text{kW}}{(120\,\text{km})^2} = \boxed{4.14\,\mu\text{W/m}^2}$$

28 ••• Regulations require that licensed radio stations have limits on their broadcast power so as to avoid interference with signals from distant stations. You are in charge of checking compliance with the law. At a distance of 30.0 km from a radio station that broadcasts from a single vertical electric dipole antenna at a frequency of 800 kHz, the intensity of the electromagnetic wave is 2.00×10^{-13} W/m^2. What is the total power radiated by the station?

Picture the Problem The intensity of radiation from an electric dipole is given by $C(\sin^2\theta)/r^2$, where C is a constant whose units are those of power, r is the distance from the dipole to the point of interest, and θ is the angle between the electric dipole moment and the position vector $\vec{r}$. We can integrate the intensity to express

the total power radiated by the antenna and use this result to evaluate C. Knowing C we can find the total power radiated by the station.

From the definition of intensity we have:

$$dP = IdA$$

and

$$P_{\text{tot}} = \iint I(r,\theta)\,dA$$

where, in polar coordinates,

$$dA = r^2 \sin\theta\, d\theta\, d\phi$$

Substitute for dA to obtain:

$$P_{\text{tot}} = \int_0^{2\pi}\int_0^{\pi} I(r,\theta) r^2 \sin\theta\, d\theta\, d\phi \quad (1)$$

Express the intensity of the signal as a function of r and θ:

$$I(r,\theta) = C\frac{\sin^2\theta}{r^2} \quad (2)$$

Substitute for $I(r,\theta)$ in equation (1) to obtain:

$$P_{\text{tot}} = C\int_0^{2\pi}\int_0^{\pi} \sin^3\theta\, d\theta\, d\phi$$

From integral tables we find that:

$$\int_0^{\pi} \sin^3\theta d\theta = -\tfrac{1}{3}\cos\theta\left(\sin^2\theta + 2\right)\Big]_0^{\pi} = \frac{4}{3}$$

Substitute and integrate with respect to ϕ to obtain:

$$P_{\text{tot}} = \frac{4}{3}C\int_0^{2\pi} d\phi = \frac{4}{3}C[\phi]_0^{2\pi} = \frac{8\pi}{3}C$$

From equation (2) we have:

$$C = \frac{I(r,\theta)r^2}{\sin^2\theta}$$

Substitute for C in the expression for P_{tot} to obtain:

$$P_{\text{tot}} = \frac{8\pi}{3}\frac{I(r,\theta)r^2}{\sin^2\theta}$$

or, because $\theta = 90°$,

$$P_{\text{tot}} = \frac{8\pi}{3} I(r) r^2$$

Substitute numerical values and evaluate P_{tot}:

$$P_{\text{tot}} = \frac{8\pi}{3}\left(2.00\times10^{-13}\ \text{W/m}^2\right)\left(30.0\,\text{km}\right)^2 = \boxed{1.51\,\text{mW}}$$

29 ••• A small private plane approaching an airport is flying at an altitude of 2.50 km above sea level. As a flight controller at the airport, you know your

system uses a vertical electric dipole antenna to transmit 100 W at 24.0 MHz. What is the intensity of the signal at the plane's receiving antenna when the plane is 4.00 km from the airport? Assume the airport is at sea level.

Picture the Problem The intensity of radiation from the airport's vertical dipole antenna is given by $C(\sin^2\theta)/r^2$, where C is a constant whose units are those of power, r is the distance from the dipole to the point of interest, and θ is the angle between the electric dipole moment and the position vector $\vec{r}$. We can integrate the intensity to express the total power radiated by the antenna and use this result to evaluate C. Knowing C we can find the intensity of the signal at the plane's elevation and distance from the airport.

Express the intensity of the signal as a function of r and θ:

$$I(r,\theta) = C\frac{\sin^2\theta}{r^2} \qquad (1)$$

From the definition of intensity we have:

$$dP = IdA$$

and

$$P_{\text{tot}} = \iint I(r,\theta)dA$$

where, in polar coordinates,

$$dA = r^2 \sin\theta \, d\theta \, d\phi$$

Substitute for dA to obtain:

$$P_{\text{tot}} = \int_0^{2\pi}\int_0^{\pi} I(r,\theta) r^2 \sin\theta \, d\theta \, d\phi$$

Substituting for $I(r,\theta)$ yields:

$$P_{\text{tot}} = C\int_0^{2\pi}\int_0^{\pi} \sin^3\theta \, d\theta \, d\phi$$

From integral tables we find that:

$$\int_0^{\pi} \sin^3\theta d\theta = -\tfrac{1}{3}\cos\theta\left(\sin^2\theta + 2\right)\Big]_0^{\pi} = \frac{4}{3}$$

Substitute and integrate with respect to ϕ to obtain:

$$P_{\text{tot}} = \frac{4}{3}C\int_0^{2\pi} d\phi = \frac{4}{3}C[\phi]_0^{2\pi} = \frac{8\pi}{3}C$$

Solving for C yields:

$$C = \frac{3}{8\pi}P_{\text{tot}}$$

Substitute for C in equation (1) to obtain:

$$I(r,\theta) = \frac{3P_{\text{tot}}}{8\pi}\frac{\sin^2\theta}{r^2}$$

At the elevation of the plane:

$$\theta = \tan^{-1}\left(\frac{4000\,\text{m}}{2500\,\text{m}}\right) = 58.0°$$

and

$$r = \sqrt{(2500\,\text{m})^2 + (4000\,\text{m})^2} = 4717\,\text{m}$$

Substitute numerical values and evaluate $I(4717\text{ m}, 58°)$:

$$I(4717\,\text{m}, 58.0°) = \frac{3(100\,\text{W})}{8\pi}\frac{\sin^2 58.0°}{(4717\,\text{m})^2}$$
$$= \boxed{386\ \text{nW/m}^2}$$

Energy and Momentum in an Electromagnetic Wave

30 • An electromagnetic wave has an intensity of 100 W/m^2. Find its (*a*) rms electric field strength, and (*b*) rms magnetic field strength.

Picture the Problem We can use $P_r = I/c$ to find the radiation pressure. The intensity of the electromagnetic wave is related to the rms values of its electric and magnetic field strengths according to $I = E_{rms}B_{rms}/\mu_0$, where $B_{rms} = E_{rms}/c$.

(*a*) Relate the intensity of the electromagnetic wave to E_{rms} and B_{rms}:

$$I = \frac{E_{rms}B_{rms}}{\mu_0}$$

or, because $B_{rms} = E_{rms}/c$,

$$I = \frac{E_{rms}\,E_{rms}/c}{\mu_0} = \frac{E_{rms}^2}{\mu_0 c}$$

Solving for E_{rms} yields:

$$E_{rms} = \sqrt{\mu_0 cI}$$

Substitute numerical values and evaluate E_{rms}:

$$E_{rms} = \sqrt{(4\pi\times10^{-7}\ \text{N/A}^2)(2.998\times10^8\ \text{m/s})(100\,\text{W/m}^2)} = \boxed{194\,\text{V/m}}$$

(*b*) Express B_{rms} in terms of E_{rms}:

$$B_{rms} = \frac{E_{rms}}{c}$$

Substitute numerical values and evaluate B_{rms}:

$$B_{rms} = \frac{194\,\text{V/m}}{2.998\times10^8\ \text{m/s}} = \boxed{647\,\text{nT}}$$

31 • **[SSM]** The amplitude of an electromagnetic wave's electric field is 400 V/m. Find the wave's (*a*) rms electric field strength, (*b*) rms magnetic field strength, (*c*) intensity and (*d*) radiation pressure (P_r).

Picture the Problem The rms values of the electric and magnetic fields are found from their amplitudes by dividing by the square root of two. The rms values of the electric and magnetic field strengths are related according to $B_{rms} = E_{rms}/c$. We can find the intensity of the radiation using $I = E_{rms}B_{rms}/\mu_0$ and the radiation pressure using $P_r = I/c$.

(*a*) Relate E_{rms} to E_0:

$$E_{rms} = \frac{E_0}{\sqrt{2}} = \frac{400\,\text{V/m}}{\sqrt{2}} = 282.8\,\text{V/m}$$
$$= \boxed{283\,\text{V/m}}$$

(*b*) Find B_{rms} from E_{rms}:

$$B_{rms} = \frac{E_{rms}}{c} = \frac{282.8\,\text{V/m}}{2.998\times10^8\ \text{m/s}}$$
$$= 0.9434\,\mu\text{T} = \boxed{943\ \text{nT}}$$

(*c*) The intensity of an electromagnetic wave is given by:

$$I = \frac{E_{rms}B_{rms}}{\mu_0}$$

Substitute numerical values and evaluate I:

$$I = \frac{(282.8\,\text{V/m})(0.9434\,\mu\text{T})}{4\pi\times10^{-7}\ \text{N/A}^2}$$
$$= 212.3\,\text{W/m}^2 = \boxed{212\,\text{W/m}^2}$$

(*d*) Express the radiation pressure in terms of the intensity of the wave:

$$P_r = \frac{I}{c}$$

Substitute numerical values and evaluate P_r:

$$P_r = \frac{212.3\,\text{W/m}^2}{2.998\times10^8\ \text{m/s}} = \boxed{708\ \text{nPa}}$$

32 • The rms value of an electromagnetic wave's electric field strength is 400 V/m. Find the wave's (*a*) rms magnetic field strength, (*b*) average energy density, and (*c*) intensity.

Picture the Problem Given E_{rms}, we can find B_{rms} using $B_{rms} = E_{rms}/c$. The average energy density of the wave is given by $u_{av} = E_{rms}B_{rms}/\mu_0 c$ and the intensity of the wave by $I = u_{av}c$.

(*a*) Express B_{rms} in terms of E_{rms}:

$$B_{rms} = \frac{E_{rms}}{c}$$

Substitute numerical values and evaluate B_{rms}:

$$B_{rms} = \frac{400\ \text{V/m}}{2.998\times10^{8}\ \text{m/s}} = 1.334\ \mu\text{T}$$
$$= \boxed{1.33\ \mu\text{T}}$$

(*b*) The average energy density u_{av} is given by:

$$u_{av} = \frac{E_{rms}B_{rms}}{\mu_0 c}$$

Substitute numerical values and evaluate u_{av}:

$$u_{av} = \frac{(400\ \text{V/m})(1.334\ \mu\text{T})}{(4\pi\times10^{-7}\ \text{N/A}^2)(2.998\times10^{8}\ \text{m/s})}$$
$$= 1.417\ \mu\text{J/m}^3 = \boxed{1.42\ \mu\text{J/m}^3}$$

(*c*) Express the intensity as the product of the average energy density and the speed of light in a vacuum:

$$I = u_{av}c$$

Substitute numerical values and evaluate I:

$$I = (1.417\ \mu\text{J/m}^3)(2.998\times10^{8}\ \text{m/s})$$
$$= \boxed{425\ \text{W/m}^2}$$

33 •• (*a*) An electromagnetic wave that has an intensity equal to 200 W/m^2 is normal to a black 20 cm by 30 cm rectangular card absorbs 100 percent of the wave. Find the force exerted on the card by the radiation. (*b*) Find the force exerted by the same wave if the card reflects 100 percent of the wave.

Picture the Problem We can find the force exerted on the card using the definition of pressure and the relationship between radiation pressure and the intensity of the electromagnetic wave. Note that, when the card reflects all the radiation incident on it, conservation of momentum requires that the force is doubled.

(*a*) Using the definition of pressure, express the force exerted on the card by the radiation:

$$F_r = P_r A$$

Relate the radiation pressure to the intensity of the wave:

$$P_r = \frac{I}{c}$$

Substitute for P_r to obtain:

$$F_r = \frac{IA}{c}$$

Substitute numerical values and evaluate F_r:

$$F_r = \frac{(200\,\text{W/m}^2)(0.20\,\text{m})(0.30\,\text{m})}{2.998\times10^8\ \text{m/s}} = \boxed{40\,\text{nN}}$$

(*b*) If the card reflects all of the radiation incident on it, the force exerted on the card is doubled:

$$F_r = \boxed{80\,\text{nN}}$$

34 •• Find the force exerted by the electromagnetic wave on the card in Part (*b*) of Problem 33 if both the incident and reflected rays are at angles of 30º to the normal.

Picture the Problem Only the normal component of the radiation pressure exerts a force on the card.

Using the definition of pressure, express the force exerted on the card by the radiation:

$$F_r = 2P_r A\cos\theta$$

where the factor of 2 is a consequence of the fact that the card reflects the radiation incident on it.

Relate the radiation pressure to the intensity of the wave:

$$P_r = \frac{I}{c}$$

Substitute for P_r to obtain:

$$F_r = \frac{2IA\cos\theta}{c}$$

Substitute numerical values and evaluate F_r:

$$F_r = \frac{2(200\,\text{W/m}^2)(0.20\,\text{m})(0.30\,\text{m})\cos 30^\circ}{2.998\times10^8\ \text{m/s}} = \boxed{69\,\text{nN}}$$

35 • **[SSM]** (*a*) For a given distance from a radiating electric dipole, at what angle (expressed as θ and measured from the dipole axis) is the intensity equal to 50 percent of the maximum intensity? (*b*) At what angle θ is the intensity equal to 1 percent of the maximum intensity?

Picture the Problem At a fixed distance from the electric dipole, the intensity of radiation is a function θ alone.

(*a*) The intensity of the radiation from the dipole is proportional to $\sin^2\theta$:

$$I(\theta) = I_0 \sin^2\theta \qquad (1)$$

where I_0 is the maximum intensity.

For $I = \frac{1}{2}I_0$: $\frac{1}{2}I_0 = I_0 \sin^2\theta \Rightarrow \sin^2\theta = \frac{1}{2}$

Solving for θ yields: $\theta = \sin^{-1}\left(\sqrt{\frac{1}{2}}\right) = \boxed{45°}$

(*b*) For $I = 0.01I_0$: $0.01I_0 = I_0 \sin^2\theta \Rightarrow \sin^2\theta = 0.01$

Solving for θ yields: $\theta = \sin^{-1}\left(\sqrt{0.01}\right) = \boxed{5.7°}$

36 •• A laser pulse has an energy of 20.0 J and a beam radius of 2.00 mm. The pulse duration is 10.0 ns and the energy density is uniformly distributed within the pulse. (*a*) What is the spatial length of the pulse? (*b*) What is the energy density within the pulse? (*c*) Find the rms values of the electric and magnetic fields in the pulse.

Picture the Problem The spatial length *L* of the pulse is the product of its speed *c* and duration Δ*t*. We can find the energy density within the pulse using its definition (*u* = *U*/*V*). The electric amplitude of the pulse is related to the energy density in the beam according to $u = \epsilon_0 E^2$ and we can find *B* from *E* using *B* = *E*/*c*.

(*a*) The spatial length *L* of the pulse is the product of its speed *c* and duration Δ*t*:

$$L = c\Delta t$$

Substitute numerical values and evaluate *L*:

$$L = \left(2.998\times10^8\ \text{m/s}\right)\left(10.0\,\text{ns}\right) = 2.998\ \text{m} = \boxed{3.00\,\text{m}}$$

(*b*) The energy density within the pulse is the energy of the beam per unit volume:

$$u = \frac{U}{V} = \frac{U}{\pi r^2 L}$$

Substitute numerical values and evaluate *u*:

$$u = \frac{20.0\,\text{J}}{\pi\left(2.00\,\text{mm}\right)^2\left(2.998\,\text{m}\right)} = 530.9\,\text{kJ/m}^3 = \boxed{531\,\text{kJ/m}^3}$$

(*c*) *E* is related to *u* according to:

$$u = \epsilon_0 E_{\text{rms}}^2 \Rightarrow E_{\text{rms}} = \sqrt{\frac{u}{\epsilon_0}}$$

Substitute numerical values and evaluate E_{rms}:

$$E_{rms} = \sqrt{\frac{530.9\ \text{kJ/m}^3}{8.854\times10^{-12}\ \text{C}^2/\text{N}\cdot\text{m}^2}} = 244.9\,\text{MV/m} = \boxed{245\,\text{MV/m}}$$

Use $B_{rms} = E_{rms}/c$ to find B_{rms}:

$$B_{rms} = \frac{244.9\ \text{MV/m}}{2.998\times10^8\ \text{m/s}} = \boxed{0.817\,\text{T}}$$

37 •• **[SSM]** An electromagnetic plane wave has an electric field that is parallel to the y axis, and has a Poynting vector that is given by $\vec{S}(x,t) = (100\ \text{W/m}^2)\cos^2[kx-\omega t]\,\hat{i}$, where x is in meters, $k = 10.0$ rad/m, $\omega = 3.00 \times 10^9$ rad/s, and t is in seconds. (*a*) What is the direction of propagation of the wave? (*b*) Find the wavelength and frequency of the wave. (*c*) Find the electric and magnetic fields of the wave as functions of x and t.

Picture the Problem We can determine the direction of propagation of the wave, its wavelength, and its frequency by examining the argument of the cosine function. We can find E from $|\vec{S}| = E^2/\mu_0 c$ and B from $B = E/c$. Finally, we can use the definition of the Poynting vector and the given expression for $\vec{S}$ to find $\vec{E}$ and $\vec{B}$.

(*a*) Because the argument of the cosine function is of the form $kx-\omega t$, the wave propagates in the $+x$ direction.

(*b*) Examining the argument of the cosine function, we note that the wave number k of the wave is:

$$k = \frac{2\pi}{\lambda} = 10.0\,\text{m}^{-1} \Rightarrow \lambda = \boxed{0.628\,\text{m}}$$

Examining the argument of the cosine function, we note that the angular frequency ω of the wave is:

$$\omega = 2\pi f = 3.00\times10^9\ \text{s}^{-1}$$

Solving for f yields:

$$f = \frac{3.00\times10^9\ \text{s}^{-1}}{2\pi} = \boxed{477\,\text{MHz}}$$

(*c*) Express the magnitude of $\vec{S}$ in terms of E:

$$|\vec{S}| = \frac{E^2}{\mu_0 c} \Rightarrow E = \sqrt{\mu_0 c|\vec{S}|}$$

Substitute numerical values and evaluate E:

$$E = \sqrt{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(2.998\times10^{8}\ \text{m/s}\right)\left(100\ \text{W/m}^2\right)} = 194.1\ \text{V/m}$$

Because $\vec{S}(x,t) = \left(100\ \text{W/m}^2\right)\cos^2[kx-\omega t]\,\hat{\boldsymbol{i}}$ and $\vec{S} = \dfrac{1}{\mu_0}\vec{E}\times\vec{B}$:

$$\vec{E}(x,t) = \boxed{\left(194\ \text{V/m}\right)\cos[kx-\omega t]\,\hat{\boldsymbol{j}}}$$

where $k = 10.0$ rad/m and $\omega = 3.00 \times 10^9$ rad/s.

Use $B = E/c$ to evaluate B:

$$B = \frac{194.1\ \text{V/m}}{2.998\times10^{8}\ \text{m/s}} = 647.4\ \text{nT}$$

Because $\vec{S} = \dfrac{1}{\mu_0}\vec{E}\times\vec{B}$, the direction of $\vec{B}$ must be such that the cross product of $\vec{E}$ with $\vec{B}$ is in the $+x$ direction:

$$\vec{B}(x,t) = \boxed{\left(647\ \text{nT}\right)\cos[kx-\omega t]\,\hat{\boldsymbol{k}}}$$

where $k = 10.0$ rad/m and $\omega = 3.00 \times 10^9$ rad/s.

38 •• A parallel-plate capacitor is being charged. The capacitor consists of a pair of identical circular parallel plates that have radius b and a separation distance d. (*a*) Show that the displacement current in the capacitor gap has the same value as the conduction current in the capacitor leads. (*b*) What is the direction of the Poynting vector in the region between the capacitor plates? (*c*) Find an expression for the Poynting vector in this region and show that its flux into the region between the plates is equal to the rate of change of the energy stored in the capacitor.

Picture the Problem We can use the expression for the electric field strength between the plates of the parallel-plate capacitor and the definition of the displacement current to show that the displacement current in the capacitor is equal to the conduction current in the capacitor leads. In (*b*) we can use the definition of the Poynting vector and the directions of the electric and magnetic fields to determine the direction of the Poynting vector between the capacitor plates. In (*c*), we'll demonstrate that the flux of $\vec{S}$ into the region between the plates is equal to the rate of change of the energy stored in the capacitor by evaluating these quantities separately and showing that they are equal.

(*a*) The displacement current is proportional to the rate at which the flux is changing between the plates:

$$I_d = \epsilon_0\frac{d\phi_e}{dt} = \epsilon_0\frac{d}{dt}(AE) = \epsilon_0 A\frac{dE}{dt}$$

The electric field strength between the plates of the capacitor is given by:

$$E = \frac{Q}{\in_0 A}$$

where Q is the instantaneous charge on the capacitor plates.

Substituting for E yields:

$$I_d = \in_0 A \frac{d}{dt} \frac{Q}{\in_0 A} = \frac{dQ}{dt} = \boxed{I}$$

(b) Because $\vec{E}$ is perpendicular to the plates of the capacitor and $\vec{B}$ is tangent to circles that are concentric and whose center is through the middle of the capacitor plates, $\vec{S}$ points radially inward toward the center of the capacitor.

(c) The Poynting vector is:

$$\vec{S} = \frac{1}{\mu_0} \vec{E} \times \vec{B} \qquad (1)$$

Letting the direction of $\vec{E}$ be the $+x$ direction:

$$\vec{E} = E\hat{i}$$

where E is the electric field strength between the plates of the capacitor.

Apply Ampere's law to a closed circular path of radius $R \leq b$ to obtain:

$$B(2\pi R) = \mu_0 I_d$$

Substituting for I_d and simplifying yields:

$$B(2\pi R) = \mu_0 \in_0 \frac{d\phi_e}{dt} = \mu_0 \in_0 \frac{d}{dt} EA$$

$$= \mu_0 \in_0 \pi R^2 \frac{dE}{dt}$$

Solve for B to obtain:

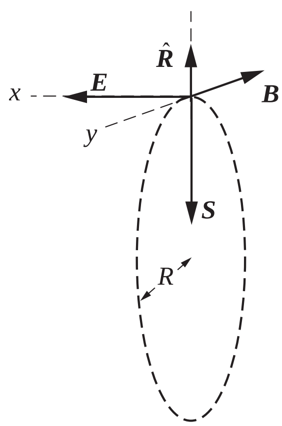
$$B = \frac{\mu_0 \in_0}{2} R \frac{dE}{dt}$$

and

$$\vec{B} = -\frac{\mu_0 \in_0}{2} R \frac{dE}{dt} \hat{j}$$

where $\hat{j}$ is a unit vector that is tangent to the concentric circles.

Substitute for $\vec{B}$ and $\vec{E}$ in equation (1) and simplify to obtain:



$$\vec{S} = \left(\frac{1}{\mu_0}E\right)\hat{i} \times \left(-\frac{\mu_0 \in_0}{2}R\frac{dE}{dt}\right)\hat{j}$$
$$= \frac{\in_0 E}{2}\frac{dE}{dt}R\left(\hat{i} \times -\hat{j}\right)$$
$$= \boxed{-\frac{\in_0 E}{2}\frac{dE}{dt}R\hat{R}}$$

where $R \leq b$, E is the electric field strength between the plates, R is the radial distance from the line joining the centers of the plates, $\hat{R}$ is a unit vector pointing radially outward from the line joining the centers of the plates, and b is the radius of the plates.

The rate at which energy is stored in the capacitor is:

$$\frac{dU}{dt} = \frac{d}{dt}(uV) = V\frac{d}{dt}\left(\in_0 E^2\right)$$
$$= Ad \in_0 E\frac{dE}{dt}$$

Because $E = \dfrac{Q}{\in_0 A}$:

$$\frac{dU}{dt} = Ad \in_0 \left(\frac{Q}{\in_0 A}\right)\frac{d}{dt}\left(\frac{Q}{\in_0 A}\right)$$
$$= \frac{Qd}{\in_0 A}\frac{dQ}{dt} = \frac{Qd}{\in_0 A}I$$

Consider a cylindrical surface of length d and radius b. Because $\vec{S}$ points inward, the energy flowing into the solenoid per unit time is:

$$\oint S_{\text{n}} dA = S(2\pi bd)$$
$$= \left(\tfrac{1}{2}\in_0 Eb\frac{dE}{dt}\right)(2\pi bd)$$
$$= \pi \in_0 Eb^2 d\frac{dE}{dt}$$

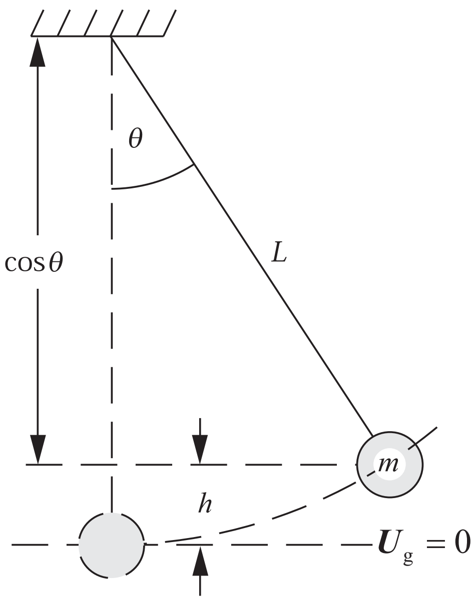
Substituting for E and simplifying yields:

$$\oint S_{\text{n}} dA = \pi \in_0 \left(\frac{Q}{\in_0 A}\right)b^2 d\frac{d}{dt}\left(\frac{Q}{\in_0 A}\right)$$
$$= \pi\left(\frac{Q}{\pi b^2}\right)\frac{b^2 d}{\in_0 A}\frac{dQ}{dt} = \frac{Qd}{\in_0 A}I$$

Because $\oint S_{\text{n}} dA = dU/dt$, we've proved that the flux of $\vec{S}$ into the region between the capacitor is equal to the rate of change of the energy stored in the capacitor.

39 •• **[SSM]** A pulsed laser fires a 1000-MW pulse that has a 200-ns duration at a small object that has a mass equal to 10.0 mg and is suspended by a fine fiber that is 4.00 cm long. If the radiation is completely absorbed by the object, what is the maximum angle of deflection of this pendulum? (Think of the system as a ballistic pendulum and assume the small object was hanging vertically before the radiation hit it.)

Picture the Problem The diagram shows the displacement of the pendulum bob, through an angle θ, as a consequence of the complete absorption of the radiation incident on it. We can use conservation of energy (mechanical energy is conserved *after* the collision) to relate the maximum angle of deflection of the pendulum to the initial momentum of the pendulum bob. Because the displacement of the bob during the absorption of the pulse is negligible, we can use conservation of momentum (conserved *during* the collision) to equate the momentum of the electromagnetic pulse to the initial momentum of the bob.



Apply conservation of energy to obtain:

$$K_f - K_i + U_f - U_i = 0$$

or, because $U_i = K_f = 0$ and $K_i = \dfrac{p_i^2}{2m}$,

$$-\frac{p_i^2}{2m} + U_f = 0$$

U_f is given by:

$$U_f = mgh = mgL(1-\cos\theta)$$

Substitute for U_f:

$$-\frac{p_i^2}{2m} + mgL(1-\cos\theta) = 0$$

Solve for θ to obtain:

$$\theta = \cos^{-1}\left(1 - \frac{p_i^2}{2m^2gL}\right)$$

Use conservation of momentum to relate the momentum of the electromagnetic pulse to the initial momentum p_i of the pendulum bob:

$$p_{\text{em wave}} = \frac{U}{c} = \frac{P\Delta t}{c} = p_i$$

where Δt is the duration of the pulse.

Substitute for p_i:

$$\theta = \cos^{-1}\left[1 - \frac{P^2(\Delta t)^2}{2m^2c^2gL}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left[1 - \frac{(1000\,\text{MW})^2(200\,\text{ns})^2}{2(10.0\,\text{mg})^2(2.998\times10^8\ \text{m/s})^2(9.81\,\text{m/s}^2)(0.0400\,\text{m})}\right] = \boxed{6.10°}$$

Remarks: The solution presented here is valid only if the displacement of the bob during the absorption of the pulse is negligible. (Otherwise, the horizontal component of the momentum of the pulse-bob system is not conserved during the collision.) We can show that the displacement during the pulse-bob collision is small by solving for the speed of the bob after absorbing the pulse. Applying conservation of momentum ($mv = P(\Delta t)/c$) and solving for v gives $v = 6.67 \times 10^{-7}$ m/s. This speed is so slow compared to c, we can conclude that the duration of the collision is extremely close to 200 ns (the time for the pulse to travel its own length). Traveling at 6.67×10^{-7} m/s for 200 ns, the bob would travel 1.33×10^{-13} m—a distance 1000 times smaller that the diameter of a hydrogen atom. (Because 6.67×10^{-7} m/s is the maximum speed of the bob during the collision, the bob would actually travel less than 1.33×10^{-13} m during the collision.)

40 •• The mirrors used in a particular type of laser are 99.99% reflecting. (*a*) If the laser has an average output power of 15 W, what is the average power of the radiation incident on one of the mirrors? (*b*) What is the force due to radiation pressure on one of the mirrors?

Picture the Problem We can use the definitions of pressure and the relationship between radiation pressure and the intensity of the radiation to find the force due to radiation pressure on one of the mirrors.

(*a*) Because only about 0.01 percent of the energy inside the laser "leaks out", the average power of the radiation incident on one of the mirrors is:

$$P = \frac{15\,\text{W}}{1.0\times10^{-4}} = \boxed{1.5\times10^5\ \text{W}}$$

(*b*) Use the definition of radiation pressure to obtain:

$$P_r = \frac{F_r}{A}$$

where F_r is the force due to radiation pressure and A is the area of the mirror on which the radiation is incident.

The radiation pressure is also related to the intensity of the radiation:

$$P_r = \frac{2I}{c} = \frac{2P}{Ac}$$

where P is the power of the laser and the factor of 2 is due to the fact that the mirror is essentially totally reflecting.

Equate the two expression for the radiation pressure and solve for F_r:

$$\frac{F_r}{A} = \frac{2P}{Ac} \Rightarrow F_r = \frac{2P}{c}$$

Substitute numerical values and evaluate F_r:

$$F_r = \frac{2\left(1.5\times10^5\ \text{W}\right)}{2.998\times10^8\ \text{m/s}} = \boxed{1.0\,\text{mN}}$$

41 •• **[SSM]** (*a*) Estimate the force on Earth due to the pressure of the radiation on Earth by the Sun, and compare this force to the gravitational force of the Sun on Earth. (At Earth's orbit, the intensity of sunlight is 1.37 kW/m^2.) (*b*) Repeat Part (*a*) for Mars which is at an average distance of 2.28×10^8 km from the Sun and has a radius of 3.40×10^3 km. (*c*) Which planet has the larger ratio of radiation pressure to gravitational attraction.

Picture the Problem We can find the radiation pressure force from the definition of pressure and the relationship between the radiation pressure and the intensity of the radiation from the Sun. We can use Newton's law of gravitation to find the gravitational force the Sun exerts on Earth and Mars.

(*a*) The radiation pressure exerted on Earth is given by:

$$P_{\text{r, Earth}} = \frac{F_{\text{r, Earth}}}{A} \Rightarrow F_{\text{r, Earth}} = P_{\text{r, Earth}}A$$

where A is the cross-sectional area of Earth.

Express the radiation pressure in terms of the intensity of the radiation I from the Sun:

$$P_{\text{r, Earth}} = \frac{I}{c}$$

Substituting for $P_{\text{r, Earth}}$ and A yields:

$$F_{\text{r, Earth}} = \frac{I\pi R^2}{c}$$

Substitute numerical values and evaluate F_r:

$$F_{\text{r, Earth}}=\frac{\pi\left(1.37\ \text{kW/m}^2\right)\left(6.37\times10^6\ \text{m}\right)^2}{2.998\times10^8\ \text{m/s}}=5.825\times10^8\ \text{N}=\boxed{5.83\times10^8\ \text{N}}$$

The gravitational force exerted on Earth by the Sun is given by:

$$F_{\text{g, Earth}}=\frac{Gm_{\text{sun}}m_{\text{earth}}}{r^2}$$

where r is the radius of Earth's orbit.

Substitute numerical values and evaluate $F_{\text{g, Earth}}$:

$$F_{\text{g, Earth}}=\frac{\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(1.99\times10^{30}\ \text{kg}\right)\left(5.98\times10^{24}\ \text{kg}\right)}{\left(1.50\times10^{11}\ \text{m}\right)^2}=3.529\times10^{22}\ \text{N}$$

Express the ratio of the force due to radiation pressure $F_{\text{r, Earth}}$ to the gravitational force $F_{\text{g, Earth}}$:

$$\frac{F_{\text{r, Earth}}}{F_{\text{g, Earth}}}=\frac{5.825\times10^8\ \text{N}}{3.529\times10^{22}\ \text{N}}=1.65\times10^{-14}$$

or

$$F_{\text{r, Earth}}=\boxed{\left(1.65\times10^{-14}\right)F_{\text{g, Earth}}}$$

(*b*) The radiation pressure exerted on Mars is given by:

$$P_{\text{r, Mars}}=\frac{F_{\text{r, Mars}}}{A}\Rightarrow F_{\text{r, Mars}}=P_{\text{r, Mars}}A$$

where A is the cross-sectional area of Mars.

Express the radiation pressure on Mars in terms of the intensity of the radiation I_{Mars} from the sun:

$$P_{\text{r, Mars}}=\frac{I_{\text{Mars}}}{c}$$

Substituting for $P_{\text{r, Mars}}$ and A yields:

$$F_{\text{r, Mars}}=\frac{I_{\text{Mars}}\pi R_{\text{Mars}}^2}{c}$$

Express the ratio of the solar constant at Earth to the solar constant at Mars:

$$\frac{I_{\text{Mars}}}{I_{\text{earth}}}=\left(\frac{r_{\text{earth}}}{r_{\text{Mars}}}\right)^2\Rightarrow I_{\text{Mars}}=I_{\text{earth}}\left(\frac{r_{\text{earth}}}{r_{\text{Mars}}}\right)^2$$

Substitute for I_{Mars} to obtain:

$$F_{\text{r, Mars}}=\frac{I_{\text{earth}}\pi R_{\text{Mars}}^2}{c}\left(\frac{r_{\text{earth}}}{r_{\text{Mars}}}\right)^2$$

Substitute numerical values and evaluate $F_{\text{r, Mars}}$:

$$F_{\text{r, Mars}} = \frac{\pi(1.37\,\text{kW/m}^2)(3.40\times10^3\ \text{km})^2}{2.998\times10^8\ \text{m/s}}\left(\frac{1.50\times10^{11}\ \text{m}}{2.28\times10^{11}\ \text{m}}\right)^2 = \boxed{7.18\times10^7\ \text{N}}$$

The gravitational force exerted on Mars by the Sun is given by:

$$F_{\text{g, Mars}} = \frac{Gm_{\text{sun}}m_{\text{Mars}}}{r^2} = \frac{Gm_{\text{sun}}(0.11m_{\text{Earth}})}{r^2}$$

where r is the radius of Mars' orbit.

Substitute numerical values and evaluate F_{g}

$$F_{\text{g, Mars}} = \frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})(0.11)(5.98\times10^{24}\ \text{kg})}{(2.28\times10^{11}\ \text{m})^2}$$

$$= 1.68\times10^{21}\ \text{N}$$

Express the ratio of the force due to radiation pressure $F_{\text{r, Mars}}$ to the gravitational force $F_{\text{g, Mars}}$:

$$\frac{F_{\text{r, Mars}}}{F_{\text{g, Mars}}} = \frac{7.18\times10^7\ \text{N}}{1.68\times10^{21}\ \text{N}} = 4.27\times10^{-14}$$

or

$$F_{\text{r, Mars}} = \boxed{(4.27\times10^{-14})F_{\text{g, Mars}}}$$

(c) Because the ratio of the radiation pressure force to the gravitational force is 1.65×10^{-14} for Earth and 4.27×10^{-14} for Mars, Mars has the larger ratio. The reason that the ratio is higher for Mars is that the dependence of the radiation pressure on the distance from the Sun is the same for both forces (r^{-2}), whereas the dependence on the radii of the planets is different. Radiation pressure varies as R^2, whereas the gravitational force varies as R^3 (assuming that the two planets have the same density, an assumption that is nearly true). Consequently, the ratio of the forces goes as $R^2/R^3 = R^{-1}$. Because Mars is smaller than Earth, the ratio is larger.

The Wave Equation for Electromagnetic Waves

42 • Show by direct substitution that Equation 30-8a is satisfied by the wave function $E_y = E_0 \sin(kx - \omega t) = E_0 \sin k(x - ct)$ where $c = \omega/k$.

Picture the Problem We can show that Equation 30-8a is satisfied by the wave function E_y by showing that the ratio of $\partial^2 E_y/\partial x^2$ to $\partial^2 E_y/\partial t^2$ is $1/c^2$ where $c = \omega/k$.

Differentiate $E_y = E_0 \sin(kx - \omega t)$ with respect to x:

$$\frac{\partial E_y}{\partial x} = \frac{\partial}{\partial x}\left[E_0 \sin(kx - \omega t)\right] = kE_0 \cos(kx - \omega t)$$

Evaluate the second partial derivative of E_y with respect to x:

$$\frac{\partial^2 E_y}{\partial x^2} = \frac{\partial}{\partial x}\left[kE_0 \cos(kx - \omega t)\right] = -k^2 E_0 \sin(kx - \omega t) \quad (1)$$

Differentiate $E_y = E_0 \sin(kx - \omega t)$ with respect to t:

$$\frac{\partial E_y}{\partial t} = \frac{\partial}{\partial t}\left[E_0 \sin(kx - \omega t)\right] = -\omega E_0 \cos(kx - \omega t)$$

Evaluate the second partial derivative of E_y with respect to t:

$$\frac{\partial^2 E_y}{\partial t^2} = \frac{\partial}{\partial t}\left[-\omega E_0 \cos(kx - \omega t)\right] = -\omega^2 E_0 \sin(kx - \omega t) \quad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{\dfrac{\partial^2 E_y}{\partial x^2}}{\dfrac{\partial^2 E_y}{\partial t^2}} = \frac{-k^2 E_0 \sin(kx - \omega t)}{-\omega^2 E_0 \sin(kx - \omega t)} = \frac{k^2}{\omega^2}$$

or

$$\frac{\partial^2 E_y}{\partial x^2} = \frac{k^2}{\omega^2}\frac{\partial^2 E_y}{\partial t^2} = \frac{1}{c^2}\frac{\partial^2 E_y}{\partial t^2}$$

provided $c = \omega/k$.

43 • Use the values of μ_0 and $\in_0$ in SI units to compute $1/\sqrt{\in_0 \mu_0}$ and show that it is equal to 3.00×10^8 m/s.

Picture the Problem Substitute numerical values and evaluate c:

$$c = \frac{1}{\sqrt{\left(4\pi \times 10^{-7}\ \mathrm{N/A^2}\right)\left(8.854 \times 10^{-12}\ \mathrm{C^2/N \cdot m^2}\right)}} = \boxed{3.00 \times 10^8\ \mathrm{m/s}}$$

44 •• (*a*) Use Maxwell's equations to show for a plane wave, in which $\vec{E}$ and $\vec{B}$ are independent of y and z, that $\dfrac{\partial E_z}{\partial x} = \dfrac{\partial B_y}{\partial t}$ and $\dfrac{\partial B_y}{\partial x} = \mu_0 \in_0 \dfrac{\partial E_z}{\partial t}$.
(*b*) Show that E_z and B_y also satisfy the wave equation.

Picture the Problem We can use Figures 30-5 and 30-6 and a derivation similar to that in the text to obtain the given results.

In Figure 30-5, replace B_z by E_z. For Δx small:

$$E_z(x_2) = E_z(x_1) + \frac{\partial E_z}{\partial x}\Delta x$$

Evaluate the line integral of $\vec{E}$ around the rectangular area $\Delta x\Delta z$:

$$\oint \vec{E}\cdot d\vec{\ell} \approx -\frac{\partial E_z}{\partial x}\Delta x\Delta z \qquad (1)$$

Express the magnetic flux through the same area:

$$\int_S B_n\,dA = B_y\Delta x\Delta z$$

Apply Faraday's law to obtain:

$$\oint \vec{E}\cdot d\vec{\ell} \approx -\frac{\partial}{\partial t}\int_S B_n\,dA = -\frac{\partial}{\partial t}\left(B_y\Delta x\Delta z\right) = -\frac{\partial B_y}{\partial t}\Delta x\Delta z$$

Substitute in equation (1) to obtain:

$$-\frac{\partial E_z}{\partial x}\Delta x\Delta z = -\frac{\partial B_y}{\partial t}\Delta x\Delta z$$

or

$$\boxed{\frac{\partial E_z}{\partial x} = \frac{\partial B_y}{\partial t}}$$

In Figure 30-6, replace E_y by B_y and evaluate the line integral of $\vec{B}$ around the rectangular area $\Delta x\Delta z$:

$$\oint \vec{B}\cdot d\vec{\ell} = \mu_0 \in_0 \int_S E_n\,dA$$

provided there are no conduction currents.

Evaluate these integrals to obtain:

$$\boxed{\frac{\partial B_y}{\partial x} = \mu_0 \in_0 \frac{\partial E_z}{\partial t}}$$

(*b*) Using the first result obtained in (*a*), find the second partial derivative of E_z with respect to x:

$$\frac{\partial}{\partial x}\left(\frac{\partial E_z}{\partial x}\right) = \frac{\partial}{\partial x}\left(\frac{\partial B_y}{\partial t}\right)$$

or

$$\frac{\partial^2 E_z}{\partial x^2} = \frac{\partial}{\partial t}\left(\frac{\partial B_y}{\partial x}\right)$$

Use the second result obtained in (*a*) to obtain:

$$\frac{\partial^2 E_z}{\partial x^2} = \frac{\partial}{\partial t}\left(\mu_0 \varepsilon_0 \frac{\partial E_z}{\partial t}\right) = \mu_0 \in_0 \frac{\partial^2 E_z}{\partial t^2}$$

or, because $\mu_0 \in_0 = 1/c^2$,

$$\boxed{\frac{\partial^2 E_z}{\partial x^2} = \frac{1}{c^2}\frac{\partial^2 E_z}{\partial t^2}}\,.$$

Using the second result obtained in (*a*), find the second partial derivative of B_y with respect to x:

$$\frac{\partial}{\partial x}\left(\frac{\partial B_y}{\partial x}\right) = \mu_0 \in_0 \frac{\partial}{\partial x}\left(\frac{\partial E_z}{\partial t}\right)$$

or

$$\frac{\partial^2 B_y}{\partial x^2} = \mu_0 \in_0 \frac{\partial}{\partial t}\left(\frac{\partial E_z}{\partial x}\right)$$

Use the first result obtained in (*a*) to obtain:

$$\frac{\partial^2 B_y}{\partial x^2} = \mu_0 \in_0 \frac{\partial}{\partial t}\left(\frac{\partial B_y}{\partial t}\right) = \mu_0 \in_0 \frac{\partial^2 B_y}{\partial t^2}$$

or, because $\mu_0 \in_0 = 1/c^2$,

$$\boxed{\frac{\partial^2 B_y}{\partial x^2} = \frac{1}{c^2}\frac{\partial^2 B_y}{\partial t^2}}\,.$$

45 •• [SSM] Show that any function of the form $y(x, t) = f(x - vt)$ or $y(x, t) = g(x + vt)$ satisfies the wave Equation 30-7

Picture the Problem We can show that these functions satisfy the wave equations by differentiating them twice (using the chain rule) with respect to x and t and equating the expressions for the second partial of f with respect to u.

Let $u = x - vt$. Then:

$$\frac{\partial f}{\partial x} = \frac{\partial u}{\partial x}\frac{\partial f}{\partial u} = \frac{\partial f}{\partial u}$$

and

$$\frac{\partial f}{\partial t} = \frac{\partial u}{\partial t}\frac{\partial f}{\partial u} = -v\frac{\partial f}{\partial u}$$

Express the second derivatives of f with respect to x and t to obtain:

$$\frac{\partial^2 f}{\partial x^2} = \frac{\partial^2 f}{\partial u^2} \text{ and } \frac{\partial^2 f}{\partial t^2} = v^2\frac{\partial^2 f}{\partial u^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{\dfrac{\partial^2 f}{\partial x^2}}{\dfrac{\partial^2 f}{\partial t^2}} = \frac{1}{v^2} \Rightarrow \boxed{\frac{\partial^2 f}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 f}{\partial t^2}}$$

Let $u = x + vt$. Then:

$$\frac{\partial f}{\partial x}=\frac{\partial u}{\partial x}\frac{\partial f}{\partial u}=\frac{\partial f}{\partial u}$$

and

$$\frac{\partial f}{\partial t}=\frac{\partial u}{\partial t}\frac{\partial f}{\partial u}=v\frac{\partial f}{\partial u}$$

Express the second derivatives of f with respect to x and t to obtain:

$$\frac{\partial^2 f}{\partial x^2}=\frac{\partial^2 f}{\partial u^2}\text{ and }\frac{\partial^2 f}{\partial t^2}=v^2\frac{\partial^2 f}{\partial u^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{\dfrac{\partial^2 f}{\partial x^2}}{\dfrac{\partial^2 f}{\partial t^2}}=\frac{1}{v^2}\Rightarrow\boxed{\frac{\partial^2 f}{\partial x^2}=\frac{1}{v^2}\frac{\partial^2 f}{\partial t^2}}$$

General Problems

46 • An electromagnetic wave has a frequency of 100 MHz and is traveling in a vacuum. The magnetic field is given by $\vec{B}(z,t)=(1.00\times10^{-8}\text{ T})\cos(kz-\omega t)\hat{i}$. (*a*) Find the wavelength and the direction of propagation of this wave. (*b*) Find the electric field vector $\vec{E}(z,t)$. (*c*) Determine the Poynting vector, and use it to find the intensity of this wave.

Picture the Problem We can use $c = f\lambda$ to find the wavelength. Examination of the argument of the cosine function will reveal the direction of propagation of the wave. We can find the magnitude, wave number, and angular frequency of the electric vector from the given information and the result of (*a*) and use these results to obtain $\vec{E}$ (*z*, *t*). Finally, we can use its definition to find the Poynting vector.

(*a*) Relate the wavelength of the wave to its frequency and the speed of light:

$$\lambda=\frac{c}{f}$$

Substitute numerical values and evaluate λ:

$$\lambda=\frac{2.998\times10^8\text{ m/s}}{100\text{MHz}}=\boxed{3.00\text{m}}$$

From the sign of the argument of the cosine function and the spatial dependence on *z*, we can conclude that the wave propagates in the +z direction.

(*b*) Express the amplitude of $\vec{E}$:

$$E = cB = (2.998\times10^{8}\ \text{m/s})(10^{-8}\ \text{T}) = 3.00\,\text{V/m}$$

Find the angular frequency and wave number of the wave:

$$\omega = 2\pi f = 2\pi(100\,\text{MHz}) = 6.28\times10^{8}\ \text{s}^{-1}$$

and

$$k = \frac{2\pi}{\lambda} = \frac{2\pi}{3.00\,\text{m}} = 2.09\,\text{m}^{-1}$$

Because $\vec{S}$ is in the positive *z* direction, $\vec{E}$ must be in the negative *y* direction in order to satisfy the Poynting vector expression:

$$\vec{E}(z,t) = \boxed{-(3.00\,\text{V/m})\cos\left[(2.09\,\text{m}^{-1})z - (6.28\times10^{8}\ \text{s}^{-1})t\right]\hat{j}}$$

(*c*) Use its definition to express and evaluate the Poynting vector:

$$\vec{S}(z,t) = \frac{1}{\mu_0}\vec{E}\times\vec{B} = \frac{-(3.00\,\text{V/m})(10^{-8}\ \text{T})}{4\pi\times10^{-7}\ \text{N/A}^2}\cos^2\left[(2.09\,\text{m}^{-1})z - (6.28\times10^{8}\ \text{s}^{-1})t\right](\hat{j}\times\hat{i})$$

or

$$\vec{S}(z,t) = \boxed{(23.9\,\text{mW/m}^2)\cos^2\left[(2.09\,\text{m}^{-1})z - (6.28\times10^{8}\ \text{s}^{-1})t\right]\hat{k}}$$

The intensity of the wave is the average magnitude of the Poynting vector. The average value of the square of the cosine function is 1/2:

$$I = \left|\vec{S}\right| = \tfrac{1}{2}(23.9\,\text{mW/m}^2) = \boxed{11.9\,\text{mW/m}^2}$$

47 •• [SSM] A circular loop of wire can be used to detect electromagnetic waves. Suppose the signal strength from a 100-MHz FM radio station 100 km distant is 4.0 μW/m^2, and suppose the signal is vertically polarized. What is the maximum rms voltage induced in your antenna, assuming your antenna is a 10.0-cm-radius loop?

Picture the Problem We can use Faraday's law to show that the maximum rms voltage induced in the loop is given by $\mathcal{E}_{\text{rms}} = A\omega B_0/\sqrt{2}$, where *A* is the area of the loop, B_0 is the amplitude of the magnetic field, and ω is the angular frequency of the wave. Relating the intensity of the radiation to B_0 will allow us to express $\mathcal{E}_{\text{rms}}$ as a function of the intensity.

The emf induced in the antenna is given by Faraday's law:

$$\mathcal{E} = -\frac{d\phi_m}{dt} = -\frac{d}{dt}\left(\vec{\boldsymbol{B}} \cdot A\hat{\boldsymbol{n}}\right) = -\frac{d}{dt}(BA)$$
$$= -A\frac{dB}{dt} = -\pi R^2 \frac{d}{dt}\left(B_0 \sin \omega t\right)$$
$$= -\pi R^2 \omega B_0 \cos \omega t = -\mathcal{E}_{peak} \cos \omega t$$

where $\mathcal{E}_{peak} = \pi R^2 \omega B_0$ and R is the radius of the loop antenna..

$\mathcal{E}_{rms}$ equals $\mathcal{E}_{peak}$ divided by the square root of 2:

$$\mathcal{E}_{rms} = \frac{\mathcal{E}_{peak}}{\sqrt{2}} = \frac{\pi R^2 \omega B_0}{\sqrt{2}} \qquad (1)$$

The intensity of the signal is given by:

$$I = \frac{E_0 B_0}{2\mu_0}$$

or, because $E_0 = cB_0$,

$$I = \frac{cB_0 B_0}{2\mu_0} = \frac{B_0^2 c}{2\mu_0}$$

Solving for B_0 yields:

$$B_0 = \sqrt{\frac{2\mu_0 I}{c}}$$

Substituting for B_0 and ω in equation (1) and simplifying yields:

$$\mathcal{E}_{rms} = \frac{\pi R^2 (2\pi f)\sqrt{\dfrac{2\mu_0 I}{c}}}{\sqrt{2}}$$
$$= 2\pi^2 R^2 f \sqrt{\frac{\mu_0 I}{c}}$$

Substitute numerical values and evaluate $\mathcal{E}_{rms}$:

$$\mathcal{E}_{rms} = 2\pi^2 (0.100\,\text{m})^2 (100\,\text{MHz}) \sqrt{\frac{\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(4.0\ \mu\text{W/m}^2\right)}{2.998\times10^8\ \text{m/s}}} = \boxed{2.6\,\text{mV}}$$

48 •• The electric field strength from a radio station some distance from the electric dipole transmitting antenna is given by $\left(1.00\times10^{-4}\ \text{N/C}\right)\cos\left(1.00\times10^{6}\ \text{rad/s}\right)t$, where t is in seconds. (*a*) What peak voltage is picked up on a 50.0-cm long wire oriented parallel with the electric field direction? (*b*) What is the maximum voltage that can be induced by this electromagnetic wave in a conducting loop of radius 20.0 cm? What orientation of the loop does this require?

Picture the Problem The voltage induced in the piece of wire is the product of the electric field and the length of the wire. The maximum rms voltage induced in the loop is given by $\mathcal{E} = A\omega B_0$, where A is the area of the loop, B_0 is the amplitude of the magnetic field, and ω is the angular frequency of the wave.

(*a*) Because E is independent of x:

$$V = E\ell$$

where ℓ is the length of the wire.

Substitute numerical values and evaluate V:

$$V = \left[\left(1.00\times10^{-4}\ \text{N/C}\right)\cos 10^6 t\right]\left(0.500\ \text{m}\right) = \left(50.0\ \mu\text{V}\right)\cos 10^6 t$$

and $V_{\text{peak}} = \boxed{50.0\ \mu\text{V}}$

(*b*) The maximum voltage induced in a loop is given by:

$$\mathcal{E} = \omega B_0 A$$

where A is the area of the loop and B_0 is the amplitude of the magnetic field.

Eliminate B_0 in favor of E_0 and substitute for A to obtain:

$$\mathcal{E} = \frac{\omega E_0 \pi R^2}{c}$$

Substitute numerical values and evaluate $\mathcal{E}$:

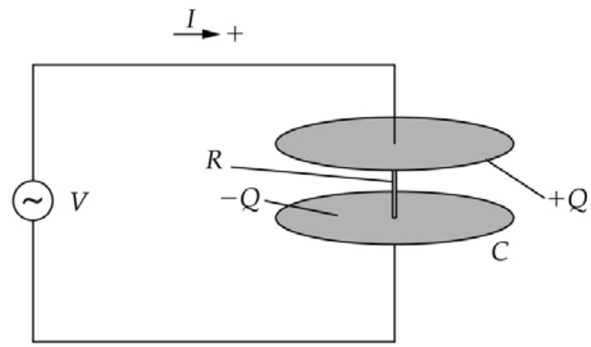
$$\mathcal{E} = \frac{\left(1.00\times10^6\ \text{s}^{-1}\right)\left(1.00\times10^{-4}\ \text{N/C}\right)\pi\left(0.200\ \text{m}\right)^2}{2.998\times10^8\ \text{m/s}} = \boxed{41.9\ \text{nV}}$$

The loop antenna should be oriented so the transmitting antenna lies in the plane of the loop.

49 ••• A parallel-plate capacitor has circular plates of radius a that are separated by a distance d. In the gap between the two plates is a thin straight wire of resistance R that connects the centers of the two plates. A time-varying voltage given by $V_0 \sin \omega t$ is applied across the plates. (*a*) What is the current drawn by this capacitor? (*b*) What is the magnetic field as a function of the radial distance r from the centerline within the capacitor plates? (*c*) What is the phase angle between the current drawn by the capacitor and the applied voltage?

Picture the Problem Some of the charge entering the capacitor passes through the resistive wire while the rest of it accumulates on the upper plate. The total current is the rate at which the charge passes through the resistive wire plus the rate at which it accumulates on the upper plate. The magnetic field between the capacitor plates is due to both the current in the resistive wire and the displacement current though a surface bounded by a circle a distance r from the

resistive wire. The phase difference between the current drawn by the capacitor and the applied voltage may be calculated using a phasor diagram.



(*a*) The current drawn by the capacitor is the sum of the conduction current through the resistance wire and *dQ/dt*, where *Q* is the charge on the upper plate of the capacitor:

$$I = I_c + \frac{dQ}{dt} \qquad (1)$$

Express the conduction current I_c in terms of the potential difference between the plates and the resistance of the wire:

$$I_c = \frac{V}{R} = \frac{V_0}{R}\sin\omega t$$

Because $Q = CV$:

$$\frac{dQ}{dt} = C\frac{dV}{dt} = \omega C V_0 \cos\omega t$$

Substitute in equation (1):

$$I = \frac{V_0}{R}\sin\omega t + \omega C V_0 \cos\omega t \qquad (2)$$

The capacitance of a parallel-plate capacitor with plate area *A* and plate separation *d* is given by:

$$C = \frac{\epsilon_0 A}{d} = \frac{\epsilon_0 \pi a^2}{d}$$

Substituting for *C* in equation (2) gives:

$$I = \boxed{V_0\left(\frac{1}{R}\sin\omega t + \frac{\omega \epsilon_0 \pi a^2}{d}\cos\omega t\right)}$$

(*b*) Apply the generalized form of Ampere's law to a circular path of radius *r* centered within the plates of the capacitor, where I'_{d} is the displacement current through the flat surface *S* bounded by the path and I_{c} is the conduction current through the same surface:

$$\oint_C \vec{\boldsymbol{B}} \cdot d\vec{\ell} = \mu_0 \left(I_{\mathrm{c}} + I'_{\mathrm{d}} \right)$$

By symmetry the line integral is *B* times the circumference of the circle of radius *r*:

$$B(2\pi r) = \mu_0 \left(I_{\mathrm{c}} + I'_{\mathrm{d}} \right) \qquad (3)$$

In the region between the capacitor plates there is a uniform electric field due to the surface charges $+Q$ and $-Q$. The associated displacement current through *S* is:

$$I'_{\mathrm{d}} = \epsilon_0 \frac{d\phi_{\mathrm{e}}}{dt} = \epsilon_0 \frac{d}{dt}(A'E)$$
$$= \epsilon_0 A' \frac{dE}{dt} = \epsilon_0 \pi r^2 \frac{dE}{dt}$$

provided $(r \le a)$

To evaluate the displacement current we first must evaluate *E* everywhere on *S*. Near the surface of a conductor, where σ is the surface charge density:

$E = \sigma / \epsilon_0$, where $\sigma = Q/A = Q/\left(\pi a^2\right)$

so

$$E = \frac{Q}{\epsilon_0 \pi a^2}$$

Substituting for *E* in the equation for I'_{d} gives:

$$I'_{\mathrm{d}} = \epsilon_0 \pi r^2 \frac{dE}{dt} = \epsilon_0 \pi r^2 \frac{d}{dt}\left(\frac{V}{d}\right)$$
$$= \frac{\epsilon_0 \pi r^2}{d} \frac{dV}{dt} = \frac{\epsilon_0 \pi r^2}{d} \frac{d}{dt}(V_0 \sin \omega t)$$
$$= \omega \frac{\epsilon_0 \pi r^2}{d} V_0 \cos \omega t$$

Solving for *B* in equation (3) and substituting for I_{c} and I'_{d} yields:

$$B(r) = \frac{\mu_0 \left(I_{\mathrm{c}} + I'_{\mathrm{d}} \right)}{2\pi r} = \frac{\mu_0}{2\pi r} \left(\frac{V_0}{R} \sin \omega t + \omega \frac{\epsilon_0 \pi r^2}{d} V_0 \cos \omega t \right)$$
$$= \boxed{\frac{\mu_0 V_0}{2\pi r} \left(\frac{1}{R} \sin \omega t + \omega \frac{\epsilon_0 \pi r^2}{d} \cos \omega t \right)}$$

(*c*) Both the charge Q and the conduction current I_c are in phase with V. However, dQ/dt, which is equal to the displacement current I_d through S for $r \geq a$, lags V by 90°. (Mathematically, cos ωt lags behind sin ωt by 90°.) The voltage V leads the current $I = I_c + I_d$ by phase angle δ. The current relation is expressed in terms of the current amplitudes:

$$I = I_c + I_d$$

or

$$I_{max}\sin(\omega t + \delta) = I_{c,max}\sin\omega t + I_{d,max}\cos\omega t$$

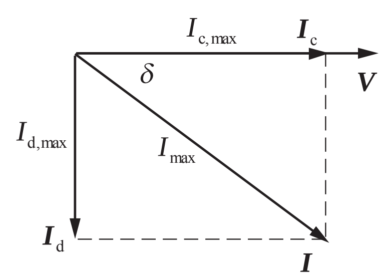
The values of the conduction and displacement current amplitudes are obtained by comparison with the answer to Part (*a*):

$$I_{c,max} = \frac{V_0}{R}$$

and

$$I_{d,max} = \frac{\omega \in_0 \pi a^2 V_0}{d}$$

A phasor diagram for adding the currents I_c and I_d is shown to the right. The conduction current I_c is in phase with the voltage V across the resistor and I_d lags behind it by 90°:



From the phasor diagram we have:

$$\tan\delta = \frac{I_{d,max}}{I_{c,max}} = \frac{V_0 \dfrac{\omega \in_0 \pi a^2}{d}}{V_0/R} = \frac{R\omega \in_0 \pi a^2}{d}$$

so

$$\delta = \boxed{\tan^{-1}\left(\frac{R\omega \in_0 \pi a^2}{d}\right)}$$

Remarks: The capacitor and the resistive wire are connected in parallel. The potential difference across each of them is the applied voltage V_0 sin ωt.

50 •• A 20-kW beam of electromagnetic radiation is normal to a surface that reflects 50 percent of the radiation. What is the force exerted by the radiation on this surface?

Picture the Problem The total force on the surface is the sum of the force due to the reflected radiation and the force due to the absorbed radiation. From the conservation of momentum, the force due to the 10 kW that are reflected is twice the force due to the 10 kW that are absorbed.

Express the total force on the surface:

$$F_{\text{tot}} = F_{\text{r}} + F_a$$

Substitute for F_{r} and F_{a} to obtain:

$$F_{\text{tot}} = \frac{2\left(\frac{1}{2}P\right)}{c} + \frac{\frac{1}{2}P}{c} = \frac{3P}{2c}$$

Substitute numerical values and evaluate F_{tot}:

$$F_{\text{tot}} = \frac{3(20\,\text{kW})}{2(2.998\times10^8\ \text{m/s})} = \boxed{0.10\,\text{mN}}$$

51 •• **[SSM]** The electric fields of two harmonic electromagnetic waves of angular frequency ω_1 and ω_2 are given by $\vec{E}_1 = E_{1,0}\cos(k_1x - \omega_1 t)\hat{j}$ and by $\vec{E}_2 = E_{2,0}\cos(k_2x - \omega_2 t + \delta)\hat{j}$. For the resultant of these two waves, find (*a*) the instantaneous Poynting vector and (*b*) the time-averaged Poynting vector. (*c*) Repeat Parts (*a*) and (*b*) if the direction of propagation of the second wave is reversed so that $\vec{E}_2 = E_{2,0}\cos(k_2x + \omega_2 t + \delta)\hat{j}$

Picture the Problem We can use the definition of the Poynting vector and the relationship between $\vec{B}$ and $\vec{E}$ to find the instantaneous Poynting vectors for each of the resultant wave motions and the fact that the time average of the cross product term is zero for $\omega_1 \neq \omega_2$, and ½ for the square of cosine function to find the time-averaged Poynting vectors.

(*a*) Because both waves propagate in the *x* direction:

$$\vec{E}\times\vec{B} = \mu_0 S\hat{i} \Rightarrow \vec{B} = B\hat{k}$$

Express B in terms of E_1 and E_2:

$$B = \frac{1}{c}(E_1 + E_2)$$

Substitute for E_1 and E_2 to obtain:

$$\vec{B}(x,t) = \frac{1}{c}\left[E_{1,0}\cos(k_1x - \omega_1 t) + E_{2,0}\cos(k_2x - \omega_2 t + \delta)\right]\hat{k}$$

The instantaneous Poynting vector for the resultant wave motion is given by:

$$\begin{aligned}\vec{S}(x,t) &= \frac{1}{\mu_0}\left(E_{1,0}\cos(k_1x-\omega_1t)+E_{2,0}\cos(k_2x-\omega_2t+\delta)\right)\hat{j}\\ &\qquad\times\frac{1}{c}\left(E_{1,0}\cos(k_1x-\omega_1t)+E_{2,0}\cos(k_2x-\omega_2t+\delta)\right)\hat{k}\\ &= \frac{1}{\mu_0c}\left(E_{1,0}\cos(k_1x-\omega_1t)+E_{2,0}\cos(k_2x-\omega_2t+\delta)\right)^2\left(\hat{j}\times\hat{k}\right)\\ &= \boxed{\begin{aligned}&\frac{1}{\mu_0c}\Big[E_{1,0}^2\cos^2(k_1x-\omega_1t)+2E_{1,0}E_{2,0}\cos(k_1x-\omega_1t)\\ &\qquad\times\cos(k_2x-\omega_2t+\delta)+E_{2,0}^2\cos^2(k_2x-\omega_2t+\delta)\Big]\hat{i}\end{aligned}}\end{aligned}$$

(*b*) The time average of the cross product term is zero for $\omega_1 \neq \omega_2$, and the time average of the square of the cosine terms is ½:

$$\vec{S}_{\text{av}} = \boxed{\frac{1}{2\mu_0c}\left[E_{1,0}^2+E_{2,0}^2\right]\hat{i}}$$

(*c*) In this case $\vec{B}_2 = -B\hat{k}$ because the wave with $k = k_2$ propagates in the $-\hat{i}$ direction. The magnetic field is then:

$$\vec{B}(x,t) = \frac{1}{c}\left[E_{1,0}\cos(k_1x-\omega_1t)-E_{2,0}\cos(k_2x+\omega_2t+\delta)\right]\hat{k}$$

The instantaneous Poynting vector for the resultant wave motion is given by:

$$\begin{aligned}\vec{S}(x,t) &= \frac{1}{\mu_0}\left(E_{1,0}\cos(k_1x-\omega_1t)+E_{2,0}\cos(k_2x-\omega_2t+\delta)\right)\hat{j}\\ &\qquad\times\frac{1}{c}\left(E_{1,0}\cos(k_1x-\omega_1t)-E_{2,0}\cos(k_2x+\omega_2t+\delta)\right)\hat{k}\\ &= \boxed{\frac{1}{\mu_0c}\left[E_{1,0}^2\cos^2(k_1x-\omega_1t)-E_{2,0}^2\cos^2(k_2x+\omega_2t+\delta)\right]\hat{i}}\end{aligned}$$

The time average of the square of the cosine terms is ½:

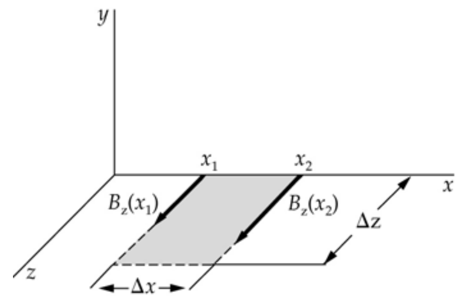
$$\vec{S}_{\text{av}} = \boxed{\frac{1}{2\mu_0c}\left[E_{1,0}^2-E_{2,0}^2\right]\hat{i}}$$

52 •• Show that $\frac{\partial B_z}{\partial x} = \mu_o \in_0 \frac{\partial E_n}{\partial t}$ (Equation 30-10) follows from $\oint_C \vec{B}\cdot d\vec{\ell} = -\mu_0 \in_0 \int_S \frac{\partial E_y}{\partial t}dA$ (Equation 30-6*d* with $I = 0$) by integrating along a

suitable curve C and over a suitable surface S in a manner that parallels the derivation of Equation 30-9.

Picture the Problem We'll choose the curve with sides Δx and Δz in the xy plane shown in the diagram and apply Equation 30-6*d* to show that

$$\frac{\partial B_z}{\partial x} = -\mu_0 \in_0 \frac{\partial E_y}{\partial t}.$$



Because Δx is very small, we can approximate the difference in B_z at the points x_1 and x_2 by:

$$B_z(x_2) - B_z(x_1) = \Delta B \approx \frac{\partial B_z}{\partial x}\Delta x$$

Then:

$$\oint_C \vec{B} \cdot d\vec{\ell} \approx \mu_0 \in_0 \frac{\partial E_y}{\partial t}\Delta x \Delta z$$

The flux of the electric field through this curve is approximately:

$$\int_S E_n dA = E_y \Delta x \Delta y$$

Apply Faraday's law to obtain:

$$\frac{\partial B_z}{\partial x}\Delta x \Delta z = -\mu_0 \in_0 \frac{\partial E_y}{\partial t}\Delta x \Delta z$$

or

$$\boxed{\frac{\partial B_z}{\partial x} = -\mu_0 \in_0 \frac{\partial E_y}{\partial t}}$$

53 •• For your backpacking excursions, you have purchased a radio capable of detecting a signal as weak as 1.00×10^{-14} W/m^2. This radio has a 2000-turn coil antenna that has a radius of 1.00 cm wound on an iron core that increases the magnetic field by a factor of 200. The broadcast frequency of the radio station is 1400 kHz. (*a*) What is the peak magnetic field strength of an electromagnetic wave of this minimum intensity? (*b*) What is the peak emf that it is capable of inducing in the antenna? (*c*) What would be the peak emf induced in a straight 2.00-m long metal wire oriented parallel to the direction of the electric field?

Picture the Problem We can use the relationship between the average value of the Poynting vector (the intensity), E_0, and B_0 to find B_0. The application of Faraday's law will allow us to find the emf induced in the antenna. The emf induced in a 2.00-m wire oriented in the direction of the electric field can be found using $\mathcal{E} = E\ell$ and the relationship between E and B.

(*a*) The intensity of the signal is related the amplitude of the magnetic field in the wave:

$$S_{av} = I = \frac{E_0B_0}{2\mu_0} = \frac{cB_0^2}{2\mu_0} \Rightarrow B_0 = \sqrt{\frac{2\mu_0 I}{c}}$$

Substitute numerical values and evaluate B_0:

$$B_0 = \sqrt{\frac{2\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(1.00\times10^{-14}\ \text{W/m}^2\right)}{2.998\times10^8\ \text{m/s}}} = \boxed{9.16\times10^{-15}\ \text{T}}$$

(*b*) Apply Faraday's law to the antenna coil to obtain:

$$\begin{aligned}|\mathcal{E}(t)| &= \frac{d}{dt}(BA) = A\frac{d}{dt}\left(NK_m B_0 \sin\omega t\right)\\ &= NK_m AB_0\omega\cos\omega t\\ &= \mathcal{E}_{peak}\cos\omega t\end{aligned}$$

where $\mathcal{E}_{peak} = NK_m AB_0\omega$

Substitute numerical values and evaluate $\mathcal{E}_{peak}$:

$$\mathcal{E}_{peak} = 2000(200)\pi(0.0100\,\text{m})^2\left(9.16\times10^{-15}\ \text{T}\right)\left[2\pi(1400\,\text{kHz})\right] = \boxed{10.1\,\mu\text{V}}$$

(*c*) The voltage induced in the wire is the product of its length ℓ and the amplitude of electric field E_0:

$$\mathcal{E} = E\ell$$

Relate E to B:

$$E = cB = cB_0\sin\omega t$$

Substitute for E to obtain:

$$\mathcal{E} = c\ell B_0\sin\omega t = \mathcal{E}_{peak}\sin\omega t$$

where $\mathcal{E}_{peak} = c\ell B_0$

Substitute numerical values and evaluate $\mathcal{E}_{peak}$:

$$\mathcal{E}_{peak} = \left(2.998\times10^8\ \text{m/s}\right)(2.00\,\text{m})\left(9.16\times10^{-15}\ \text{T}\right) = \boxed{5.49\,\mu\text{V}}$$

54 •• The intensity of the sunlight striking Earth's upper atmosphere is 1.37 kW/m^2. (*a*) Find the rms values of the magnetic and electric fields of this light. (*b*) Find the average power output of the Sun. (*c*) Find the intensity and the radiation pressure at the surface of the Sun.

Picture the Problem We can use $I = E_{rms}B_{rms}/\mu_0$ and $B_{rms} = E_{rms}/c$ to express E_{rms} in terms of I. We can then use $B_{rms} = E_{rms}/c$ to find B_{rms}. The average power output

of the Sun is given by $P_{av} = 4\pi R^2 I$ where R is the Earth-Sun distance. The intensity and the radiation pressure at the surface of the sun can be found from the definitions of these physical quantities.

(*a*) The intensity of the radiation is given by:

$$I = \frac{E_{rms}B_{rms}}{\mu_0} = \frac{E_{rms}^2}{c\mu_0} \Rightarrow E_{rms} = \sqrt{c\mu_0 I}$$

Substitute numerical values and evaluate E_{rms}:

$$E_{rms} = \sqrt{\left(2.998\times10^8\ \text{m/s}\right)\left(4\pi\times10^{-7}\ \text{N/A}^2\right)\left(1.37\,\text{kW/m}^2\right)} = 718.4\ \text{V/m}$$
$$= \boxed{718\,\text{V/m}}$$

Use $B_{rms} = E_{rms}/c$ to evaluate B_{rms}:

$$B_{rms} = \frac{718.4\,\text{V/m}}{2.998\times10^8\ \text{m/s}} = \boxed{2.40\,\mu\text{T}}$$

(*b*) Express the average power output of the Sun in terms of the solar constant:

$$P_{av} = 4\pi R^2 I$$

where R is the Earth-sun distance.

Substitute numerical values and evaluate P_{av}:

$$P_{av} = 4\pi\left(1.50\times10^{11}\ \text{m}\right)^2\left(1.37\,\text{kW/m}^2\right)$$
$$= 3.874\times10^{26}\ \text{W}$$
$$= \boxed{3.87\times10^{26}\ \text{W}}$$

(*c*) Express the intensity at the surface of the Sun in terms of the sun's average power output and radius r:

$$I = \frac{P_{av}}{4\pi r^2}$$

Substitute numerical values (see Appendix B for the radius of the Sun) and evaluate I at the surface of the Sun:

$$I = \frac{3.874\times10^{26}\ \text{W}}{4\pi\left(6.96\times10^8\ \text{m}\right)^2}$$
$$= 6.363\times10^7\ \text{W/m}^2$$
$$= \boxed{6.36\times10^7\ \text{W/m}^2}$$

Express the radiation pressure in terms of the intensity:

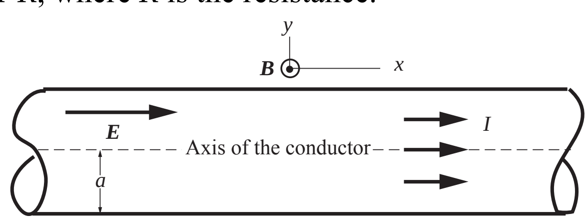
$$P_r = \frac{I}{c}$$

Substitute numerical values and evaluate P_r:

$$P_r = \frac{6.363\times10^7\ \text{W/m}^2}{2.998\times10^8\ \text{m/s}} = \boxed{0.212\,\text{Pa}}$$

55 ••• [SSM] A conductor in the shape of a long solid cylinder that has a length L, a radius a, and a resistivity ρ carries a steady current I that is uniformly distributed over its cross-section. (*a*) Use Ohm's law to relate the electric field $\vec{E}$ in the conductor to I, ρ, and a. (*b*) Find the magnetic field $\vec{B}$ just outside the conductor. (*c*) Use the results from Part (*a*) and Part (*b*) to compute the Poynting vector $\vec{S} = \left(\vec{E} \times \vec{B}\right)/\mu_0$ at $r = a$ (the edge of the conductor). In what direction is $\vec{S}$? (*d*) Find the flux $\oint S_n dA$ through the surface of the cylinder, and use this flux to show that the rate of energy flow into the conductor equals I^2R, where R is the resistance of the cylinder.

Picture the Problem A side view of the cylindrical conductor is shown in the diagram. Let the current be to the right (in the +x direction) and choose a coordinate system in which the +y direction is radially outward from the axis of the conductor. Then the +z direction is tangent to cylindrical surfaces that are concentric with the axis of the conductor (out of the plane of the diagram at the location indicated in the diagram). We can use Ohm's law to relate the electric field strength E in the conductor to I, ρ, and a and Ampere's law to find the magnetic field strength B just outside the conductor. Knowing $\vec{E}$ and $\vec{B}$ we can find $\vec{S}$ and, using its normal component, show that the rate of energy flow into the conductor equals I^2R, where R is the resistance.



(*a*) Apply Ohm's law to the cylindrical conductor to obtain:

$$V = IR = \frac{I\rho L}{A} = \frac{I\rho}{\pi a^2}L = EL$$

where $E = \dfrac{I\rho}{\pi a^2}$.

Because $\vec{E}$ is in the same direction as I:

$$\vec{E} = \boxed{\frac{I\rho}{\pi a^2}\hat{\boldsymbol{i}}}$$ where $\hat{\boldsymbol{i}}$ is a unit vector in the direction of the current.

(*b*) Applying Ampere's law to a circular path of radius a at the surface of the cylindrical conductor yields:

$$\oint_C \vec{B} \cdot d\vec{\ell} = B(2\pi a) = \mu_0 I_{\text{enclosed}} = \mu_0 I$$

Solve for the magnetic field strength B to obtain:

$$B = \frac{\mu_0 I}{2\pi a}$$

Apply a right-hand rule to determine the direction of $\vec{B}$ at the point of interest shown in the diagram:

$$\vec{B} = \boxed{\frac{\mu_0 I}{2\pi a}\hat{\theta}}$$ where $\hat{\boldsymbol{\theta}}$ is a unit vector perpendicular to $\hat{\boldsymbol{i}}$ and tangent to the surface of the conducting cylinder.

(*c*) The Poynting vector is given by:

$$\vec{S} = \frac{1}{\mu_0}\vec{E} \times \vec{B}$$

Substitute for $\vec{E}$ and $\vec{B}$ and simplify to obtain:

$$\vec{S} = \frac{1}{\mu_0}\left(\frac{I\rho}{\pi a^2}\right)\hat{\boldsymbol{i}} \times \left(\frac{\mu_0 I}{2\pi a}\right)\hat{\boldsymbol{k}} = -\frac{I^2\rho}{2\pi^2 a^3}\hat{\boldsymbol{j}}$$

Letting $\hat{\boldsymbol{r}}$ be a unit vector directed radially outward from the axis of the cylindrical conductor yields.

$$\vec{S} = \boxed{-\frac{I^2\rho}{2\pi^2 a^3}\hat{\boldsymbol{r}}}$$ where $\hat{\boldsymbol{r}}$ is a unit vector directed radially outward away from the axis of the conducting cylinder.

(*d*) The flux through the surface of the conductor into the conductor is:

$$\oint S_n dA = S(2\pi aL)$$

Substitute for S_n, the *inward* component of $\vec{S}$, and simplify to obtain:

$$\oint S_n dA = \frac{I^2\rho}{2\pi^2 a^3}(2\pi aL) = \frac{I^2\rho L}{\pi a^2}$$

Because $R = \frac{\rho L}{A} = \frac{\rho L}{\pi a^2}$:

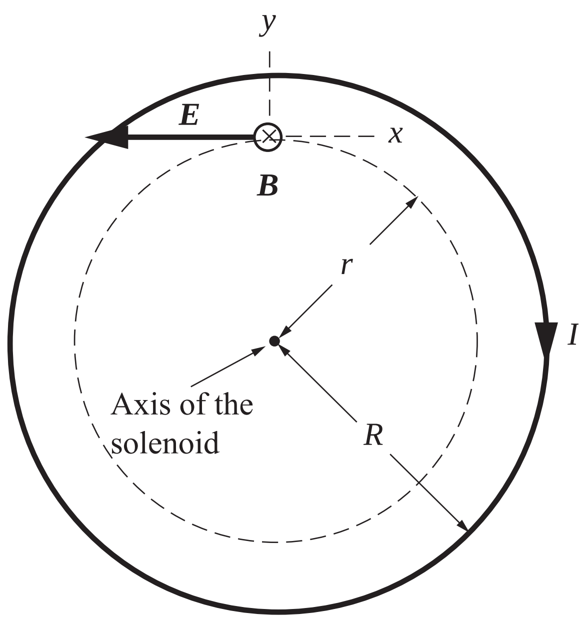
$$\oint S_n dA = \boxed{I^2 R}$$

Remarks: The equality of the two flow rates is a statement of the conservation of energy.

56 ••• A long solenoid that has n turns per unit length carries a current that increases linearly with time. The solenoid has radius R, length L, and the current I in the windings is given by $I = at$. (*a*) Find the induced electric field at a distance $r < R$ from the central axis of the solenoid. (*b*) Find the magnitude and direction of the Poynting vector $\vec{S}$ at $r = R$ (just inside the solenoid windings). (*c*) Calculate

the flux $\oint S_{\text{n}}dA$ into the region inside the solenoid, and show that this flux equals the rate of increase of the magnetic energy inside the solenoid.

Picture the Problem An end view of the solenoid is shown in the diagram. Let the current be clockwise and choose a coordinate system in which the +*x* direction is tangent to cylindrical surfaces concentric with the axis of the solenoid. Note that the +*z* direction is out of the plane of the diagram. We can use Faraday's law to express the induced electric field at a distance $r < R$ from the solenoid axis in terms of the rate of change of magnetic flux and $B = n\mu_0 at$ to express $\vec{B}$ in terms of the current in the windings of the solenoid. We can use the results of (*a*) to find the Poynting vector $\vec{S}$ at the cylindrical surface $r = R$ just inside the solenoid windings. In Part (*c*) we'll use the definition of flux and the expression for the magnetic energy in a given region to show that the flux of $\vec{S}$ into the solenoid equals the rate of increase of the magnetic energy inside the solenoid.



(*a*) Apply Faraday's law to a circular path of radius $r < R$ to relate the magnitude of the induced electric field to the magnitude of the rate of change of the magnetic flux:

$$\oint_C \vec{E}\cdot d\vec{\ell} = E(2\pi r) = -\frac{d\phi_{\text{m}}}{dt}$$

Solving for *E* yields:

$$E = -\frac{1}{2\pi r}\frac{d\phi_{\text{m}}}{dt} \qquad (1)$$

Express the magnetic field strength inside a long solenoid:

$$B = n\mu_0 I = n\mu_0 at$$

The magnetic flux through a circle of radius r is:

$$\phi_m = BA = n\mu_0 at\pi r^2$$

Substitute for ϕ_m in equation (1) and simplify to obtain:

$$E = -\frac{1}{2\pi r}\frac{d}{dt}\left[n\mu_0 at\pi r^2\right] = -\frac{n\mu_0 ar}{2}$$

The direction of $\vec{E}$ is such that it produces an emf that opposes the increase in the current, so if the current is clockwise, then $\vec{E}$ is in the opposite direction and:

$$\vec{E} = \boxed{-\tfrac{1}{2}n\mu_0 ar\hat{\theta}}$$

where $\hat{\theta}$ is a unit vector that is tangent to the circles that are concentric with the axis of the solenoid.

(*b*) Express $\vec{S}$ at $r = R$:

$$\vec{S} = \frac{1}{\mu_0}\vec{E}\times\vec{B} \qquad (2)$$

The magnitude of $\vec{B}$ is given by:

$$B = n\mu_0 I = n\mu_0 at$$

Applying a right-hand rule yields:

$$\vec{B} = -(n\mu_0 at)\hat{k}$$

Substitute for $\vec{E}$ and $\vec{B}$ in equation (2) and simplify to obtain:

$$\vec{S} = \frac{1}{\mu_0}\left(-\frac{n\mu_0 ar}{2}\right)\hat{i}\times(-n\mu_0 at)\hat{k} = -\frac{n^2\mu_0 a^2 Rt}{2}\hat{j}$$

Because $\vec{E}\times\vec{B}$ is a vector that points toward the axis of the solenoid, we can also write $\vec{S}$ as:

$$\vec{S} = \boxed{-\tfrac{1}{2}n^2\mu_0 a^2 Rt\hat{r}}$$

where $\hat{r}$ is a unit vector that points radially outward—away from the axis of the solenoid.

(*c*) Consider a cylindrical surface of length L and radius R. Because $\vec{S}$ points inward, the energy flowing into the solenoid per unit time is:

$$\oint S_n dA = 2\pi RLS = 2\pi RL\left(\frac{n^2\mu_0 a^2 Rt}{2}\right) = n^2\pi\mu_0 R^2 La^2 t$$

Express the magnetic energy in the solenoid:

$$U_B = u_m V = \frac{B^2}{2\mu_0}\left(\pi R^2 L\right) = \frac{\left(\mu_0 nat\right)^2}{2\mu_0}\left(\pi R^2 L\right) = \frac{n^2\pi\,\mu_0 R^2 La^2t^2}{2}$$

Evaluate dU_B/dt:

$$\frac{dU_B}{dt} = \frac{d}{dt}\left[\frac{n^2\pi\,\mu_0 R^2 La^2t^2}{2}\right] = \boxed{n^2\pi\,\mu_0 R^2 La^2 t} = \oint S_n\,dA$$

Remarks: The equality of the two flow rates is a statement of the conservation of energy.

57 ••• Small particles are be blown out of the solar system by the radiation pressure of sunlight. Assume that each particle is spherical, has a radius *r*, has a density of 1.00 g/cm^3, and absorbs all the radiation in a cross-sectional area of πr^2. Assume the particles are located at some distance *d* from the Sun, which has a total power output of 3.83×10^{26} W. (*a*) What is the critical value for the radius *r* of the particle for which the radiation force of repulsion just balances the gravitational force of attraction to the Sun? (*b*) Do particles that have radii larger than the critical value get ejected from the solar system, or is it only particles that have radii smaller than the critical value that get ejected? Explain your answer.

Picture the Problem We can use a condition for translational equilibrium to obtain an expression relating the forces due to gravity and radiation pressure that act on the particles. We can express the force due to radiation pressure in terms of the radiation pressure and the effective cross sectional area of the particles and the radiation pressure in terms of the intensity of the solar radiation. We can solve the resulting equation for *r*.

(*a*) Apply the condition for translational equilibrium to the particle:

$$F_r - F_g = 0$$

or, since $F_r = P_r A$ and $F_g = mg$,

$$P_r A - \frac{GM_s m}{R^2} = 0 \qquad (1)$$

The radiation pressure P_r depends on the intensity of the radiation *I*:

$$P_r = \frac{I}{c}$$

The intensity of the solar radiation at a distance R is:

$$I=\frac{P}{4\pi R^2}$$

Substitute for I to obtain:

$$P_\mathrm{r}=\frac{P}{4\pi R^2 c}$$

Substitute for P_r, A, and m in equation (1):

$$\frac{P}{4\pi R^2 c}\left(\pi r^2\right)-\frac{\frac{4}{3}\pi r^3\rho GM_\mathrm{s}}{R^2}=0$$

Solve for r to obtain:

$$r=\frac{3P}{16\pi\rho cGM_\mathrm{s}}$$

Substitute numerical values and evaluate r:

$$r=\frac{3\left(3.83\times10^{26}\ \mathrm{W}\right)}{16\pi\left(1.00\,\mathrm{g/cm^3}\right)\left(2.998\times10^{8}\ \mathrm{m/s}\right)\left(6.673\times10^{-11}\ \mathrm{N\cdot m^2/kg^2}\right)\left(1.99\times10^{30}\ \mathrm{kg}\right)}$$
$$=\boxed{574\ \mathrm{nm}}$$

(*b*) Because both the gravitational and radiation pressure forces decrease as the square of the distance from the Sun, it is then a comparison of grain mass to grain area. Since mass is proportional to volume and thus varies with the cube of the radius, the larger grains have more mass and thus experience a stronger gravitational than radiation-pressure force. The critical radius is an upper limit and so particles smaller than that radius will be blown out.

58 ••• When an electromagnetic wave at normal incidence on a perfectly conducting surface is reflected, the electric field of the reflected wave at the reflecting surface is equal and opposite to the electric field of the incident wave at the reflecting surface. (*a*) Explain why this assertion is valid. (*b*) Show that the superposition of incident and reflected waves results in a standing wave. (*c*) Are the magnetic fields of the incident waves and reflected waves at the reflecting surface equal and opposite as well? Explain your answer.

Picture the Problem

(*a*) At a perfectly conducting surface $\vec{E}=0$. Therefore, the sum of the electric fields of the incident and reflected wave must add to zero, and so $\vec{E}_\mathrm{i}=-\vec{E}_\mathrm{r}$.

(*b*) Let the incident and reflected waves be described by:

$$E_\mathrm{i}=E_{0y}\cos(\omega t-kx)$$
and
$$E_\mathrm{r}=-E_{0y}\cos(\omega t+kx)$$

Use the trigonometric identity cos($\alpha + \beta$) = cosαcosβ – sinαsinβ to obtain:

$$\begin{aligned} E_{\text{i}} + E_{\text{r}} &= E_{0y}\cos(\omega t - kx) - E_{0y}\cos(\omega t + kx) = E_{0y}[\cos(\omega t - kx) - \cos(\omega t + kx)] \\ &= E_{0y}[\cos\omega t\cos(-kx) - \sin\omega t\sin(-kx) - \cos\omega t\cos kx + \sin\omega t\sin(kx)] \\ &= E_{0y}[\cos\omega t\cos kx + \sin\omega t\sin kx - \cos\omega t\cos kx + \sin\omega t\sin kx] \\ &= \boxed{2E_{0y}\sin\omega t\sin kx} \end{aligned}$$

, the equation of a standing wave.

(c) Because $\vec{E} \times \vec{B} = \mu_0 \vec{S}$ and $\vec{S}$ is in the direction of propagation of the wave, we see that for the incident wave $B_{\text{i}} = B_z\cos(\omega t - kx)$. Since both $\vec{S}$ and E_y are reversed for the reflected wave $B_r = B_z\cos(\omega t + kx)$. So the magnetic field vectors are in the direction at the reflecting surface and add at that surface.
Hence $\vec{B} = 2\vec{B}_r$.

59 ••• [SSM] An intense point source of light radiates 1.00 MW isotropically (uniformly in all directions). The source is located 1.00 m above an infinite, perfectly reflecting plane. Determine the force that the radiation pressure exerts on the plane.

Picture the Problem Let the point source be a distance a above the plane. Consider a ring of radius r and thickness dr in the plane and centered at the point directly below the light source. Express the force on this elemental ring and integrate the resulting expression to obtain F.

The intensity anywhere along this infinitesimal ring is given by:

$$\frac{P}{4\pi(r^2 + a^2)}$$

The elemental force dF on the elemental ring of area $2\pi rdr$ is given by:

$$dF = \frac{P\,rdr}{c(r^2 + a^2)}\frac{a}{\sqrt{r^2 + a^2}} = \frac{Pardr}{c(r^2 + a^2)^{3/2}}$$

where we have taken into account that only the normal component of the incident radiation contributes to the force on the plane, and that the plane is a perfectly reflecting plane.

Integrate dF from $r = 0$ to $r = \infty$:

$$F = \frac{Pa}{c}\int_0^\infty \frac{rdr}{(r^2 + a^2)^{3/2}}$$

From integral tables:

$$\int_0^\infty \frac{r\,dr}{\left(r^2+a^2\right)^{3/2}} = \left.\frac{-1}{\sqrt{r^2+a^2}}\right]_0^\infty = \frac{1}{a}$$

Substitute to obtain:

$$F = \frac{Pa}{c}\left(\frac{1}{a}\right) = \frac{P}{c}$$

Substitute numerical values and evaluate F:

$$F = \frac{1.00\,\text{MW}}{2.998\times10^8\ \text{m/s}} = \boxed{3.34\,\text{mN}}$$

Chapter 31
Properties of Light

Conceptual Problems

1 • [SSM] A ray of light reflects from a plane mirror. The angle between the incoming ray and the reflected ray is 70°. What is the angle of reflection? (*a*) 70°, (*b*) 140°, (*c*) 35°, (*d*) Not enough information is given to determine the reflection angle.

Determine the Concept Because the angles of incidence and reflection are equal, their sum is 70° and the angle of reflection is 35°. $\boxed{(c)}$ is correct.

2 • A ray of light passes in air is incident on the surface of a piece of glass. The angle between the normal to the surface and the incident ray is 40°, and the angle between the normal and the refracted ray 28°. What is the angle between the incident ray and the refracted ray? (*a*) 12°, (*b*) 28°, (*c*) 40° ,(*d*) 68°

Determine the Concept The angle between the incident ray and the refracted ray is the difference between the angle of incidence and the angle of refraction. $\boxed{(a)}$ is correct.

3 • During a physics experiment, you are measuring refractive indices of different transparent materials using a red helium-neon laser beam. For a given angle of incidence, the beam has an angle of refraction equal to 28° in material A and an angle of refraction equal to 26° in material B. Which material has the larger index of refraction? (*a*) A, (*b*) B, (*c*) The indices of refraction are the same. (*d*) You cannot determine the relative magnitudes of the indices of refraction from the data given.

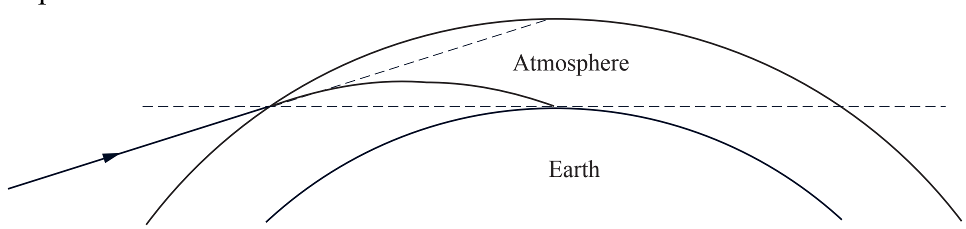
Determine the Concept The refractive index is a measure of the extent to which a material refracts light that passes through it. Because the angles of incidence are the same for materials A and B and the angle of refraction is smaller (more bending of the light) for material B, its index of refraction is larger than that of A. $\boxed{(b)}$ is correct.

4 • A ray of light passes from air into water, striking the surface of the water at an angle of incidence of 45º. Which, if any, of the following four quantities change as the light enters the water: (*a*) wavelength, (*b*) frequency, (*c*) speed of propagation, (*d*) direction of propagation, (*e*) none of the above?

Determine the Concept When light passes from air into water its wavelength changes ($\lambda_{\text{water}} = \lambda_{\text{air}}/n_{\text{water}}$), its speed changes ($v_{\text{water}} = c/n_{\text{water}}$), and the direction of its propagation changes in accordance with Snell's law. Its frequency does not change, so $\boxed{(a)}$, $\boxed{(c)}$ and $\boxed{(d)}$ change.

5 • Earth's atmosphere decreases in density as the altitude increases. As a consequence, the index of refraction of the atmosphere also decreases as altitude increases. Explain how one can see the Sun when it is below the horizon. (The horizon is the extension of a plane that is tangent to Earth's surface.) Why does the setting Sun appear flattened?

Determine the Concept The decrease in the index of refraction *n* of the atmosphere with altitude results in refraction of the light from the Sun, bending it toward the normal to the surface of Earth. Consequently, the Sun can be seen even after it is just below the horizon. The setting Sun appears flattened because refraction is greater for light from the lower part of the Sun than for light from the upper part.



6 • A physics student playing pocket billiards wants to strike her cue ball so that it hits a cushion and then hits the eight ball squarely. She chooses several points on the cushion and then measures the distances from each point to the cue ball and to the eight ball. She aims at the point for which the sum of these distances is least. (*a*) Will her cue ball hit the eight ball? (*b*) How is her method related to Fermat's principle? Neglect any effects due to ball rotation.

Determine the Concept (*a*) Yes. (*b*) Her procedure is based on Fermat's principle of least time. The ball presumably bounces off the cushion with an angle of reflection equal to the angle of incidence, just as a light ray would do if the cushion were a mirror. The least time would also be the shortest distance of travel for the light ray.

7 • **[SSM]** A swimmer at point *S* in Figure 31-53 develops a leg cramp while swimming near the shore of a calm lake and calls for help. A lifeguard at point *L* hears the call. The lifeguard can run 9.0 m/s and swim 3.0 m/s. She knows physics and chooses a path that will take the least time to reach the swimmer. Which of the paths shown in the figure does the lifeguard take?

Determine the Concept The path through point *D* is the path of least time. In analogy to the refraction of light, the ratio of the sine of the angle of incidence to the sine of the angle of refraction equals the ratio of the speeds of the lifeguard in each medium. Careful measurements from the figure show that path *LDS* is the path that best satisfies this criterion.

8 • Material A has a higher index of refraction than material B. Which material has the larger critical angle for total internal reflection when the material is in air? (*a*) A, (*b*) B, (*c*) The angles are the same. (*d*) You cannot compare the angles based on the data given.

Determine the Concept Because the product of the index of refraction on the incident side of the interface and the sine of the critical angle is equal to one (the index of refraction of air), the material with the smaller index of refraction will have the larger critical angle. $\boxed{(b)}$ is correct.

9 • **[SSM]** A human eye perceives color using a structure which is called a *cone* that is is located on the retina. Three types of molecules compose these cones and each type of molecule absorbs either red, green, or blue light by resonance absorption. Use this fact to explain why the color of an object that appears blue in air appears blue underwater, in spite of the fact that the wavelength of the light is shortened in accordance with Equation 31-6.

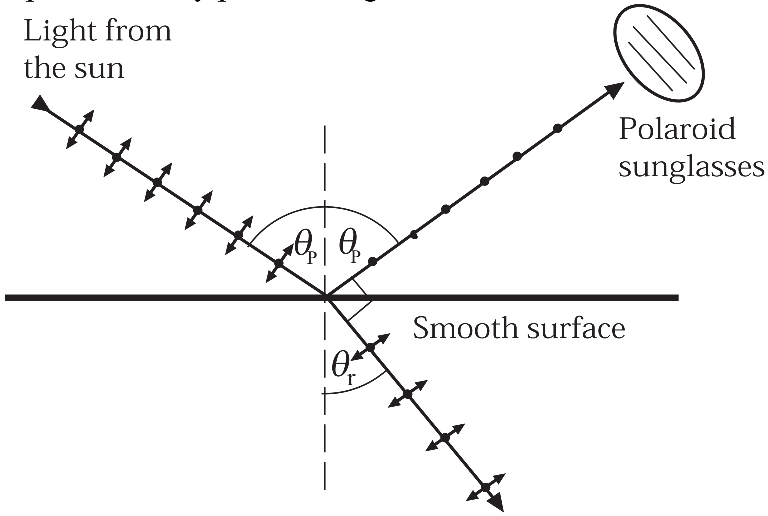
Determine the Concept In resonance absorption, the molecules respond to the frequency of the light through the Einstein photon relation $E = hf$. Neither the wavelength nor the frequency of the light within the eyeball depend on the index of refraction of the medium outside the eyeball. Thus, the color appears to be the same in spite of the fact that the wavelength has changed.

10 • Let θ be the angle between the transmission axes of two polarizing sheets. Unpolarized light of intensity I is incident upon the first sheet. What is the intensity of the light transmitted through both sheets? (*a*) $I\cos^2\theta$, (*b*) $(I\cos^2\theta)/2$, (*c*) $(I\cos^2\theta)/4$, (*d*) $I\cos\theta$, (*e*) $(I\cos\theta)/4$, (*f*) None of the above

Picture the Problem The intensity of the light transmitted by the second polarizer is given by $I_{\text{trans}} = I_0\cos^2\theta$, where $I_0 = \frac{1}{2}I$. Therefore, $I_{\text{trans}} = \frac{1}{2}I\cos^2\theta$ and $\boxed{(b)}$ is correct.

11 •• [SSM] Draw a diagram to explain how Polaroid sunglasses reduce glare from sunlight reflected from a smooth horizontal surface, such as the surface found on a pool of water. Your diagram should clearly indicate the direction of polarization of the light as it propagates from the Sun to the reflecting surface and then through the sunglasses into the eye.

Determine the Concept The following diagram shows unpolarized light from the sun incident on the smooth surface at the polarizing angle for that particular surface. The reflected light is polarized perpendicular to the plane of incidence, i.e., in the horizontal direction. The sunglasses are shown in the correct orientation to pass vertically polarized light and block the reflected sunlight.



12 • Why is it far less dangerous to stand in front of an intense beam of red light than in front of a very low-intensity beam of gamma rays?

Determine the Concept The red light photons contain considerably less energy than the gamma photons so, even though there are likely to be fewer photons in the low-intensity gamma beam, each one is potentially dangerous.

13 • Three energy states of an atom are A, B and C. State B is 2.0 eV above state A and state C is 3.00 eV above state B. Which atomic transition results in the emission of the shortest wavelength of light? (*a*) B → A, (*b*) C → B, (*c*) C → A, (*d*) A→ C

Determine the Concept Because the wavelength of the light emitted in an atomic transition is inversely proportional to the energy difference between the energy levels, the highest energy difference produces the shortest wavelength light. $\boxed{(c)}$ is correct.

14 • In Problem 13, if the atom is initially in state A, which transition results in the emission of the longest wavelength light? (*a*) A → B, (*b*) B → C, (*c*) A → C, (*d*) B→ A

Determine the Concept Because the energy required to induce an atomic transition varies inversely with the wavelength of the light that must be absorbed to induce the transition and the transition from A to B is the lowest energy transition, the transition B→ A results in the longest wavelength light. $\boxed{(d)}$ is correct.

15 • [SSM] What role does the helium play in a helium–neon laser?

Determine the Concept The population inversion between the state $E_{2,\mathrm{Ne}}$ and the state 1.96 eV below it (see Figure 31-51) is achieved by inelastic collisions between neon atoms and helium atoms excited to the state $E_{2,\mathrm{He}}$.

16 • When a beam of visible white light that passes through a gas of atomic hydrogen at room temperature is viewed with a spectroscope, dark lines are observed at the wavelengths of the hydrogen atom emission series. The atoms that participate in the resonance absorption then emit light of the same wavelength as they return to the ground state. Explain why the observed spectrum nevertheless exhibits pronounced dark lines.

Determine the Concept Although the excited atoms emit light of the same frequency on returning to the ground state, the light is emitted in a random direction, not exclusively in the direction of the incident beam. Consequently, the beam intensity is greatly diminished at this frequency.

17 • [SSM] Which of the following types of light would have the highest energy photons? (*a*) red (*b*) infrared (*c*) blue (*d*) ultraviolet

Determine the Concept The energy of a photon is directly proportional to the frequency of the light and inversely proportional to its wavelength. Of the portions of the electromagnetic spectrum include in the list of answers, ultraviolet light has the highest frequency. $\boxed{(d)}$ is correct.

Estimation and Approximation

18 • Estimate the time required for light to make the round trip during Galileo's experiment to measure the speed of light. Compare the time of the round trip to typical human response times. How accurate do you think this experiment is?

Picture the Problem We can use the distance, rate, and time relationship to estimate the time required to travel 6 km.

Express the distance d the light in Galileo's experiment traveled in terms of its speed c and the elapsed time Δt:

$$d = c\Delta t \Rightarrow \Delta t = \frac{d}{c}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{6\,\text{km}}{2.998\times10^{8}\ \text{m/s}} = \boxed{2\times10^{-5}\ \text{s}}$$

Because human reaction is approximately 0.3 s:

$$\frac{\Delta t_{\text{reaction}}}{\Delta t} = \frac{0.3\ \text{s}}{2\times10^{-5}\ \text{s}} \approx 2\times10^{4}$$

$$\text{or}\ \Delta t_{\text{reaction}} \approx \boxed{\left(2\times10^{4}\right)\Delta t}$$

Because human reaction time is so much longer than the travel time for the light, there was no way that Galileo's experiment could demonstrate that the speed of light was not infinite.

19 • Estimate the time delay in receiving a light on your retina when you are wearing eyeglasses compared to when you are not wearing your eyeglasses.

Determine the Concept We'll assume that the source of the photon is a distance L from your retina and express the difference in the photon's travel time when you are wearing your glasses. Let the thickness of your glasses by 2 mm and the index of refraction of the material from which they are constructed by 1.5.

When you are not wearing your glasses, the time required for a light photon, originating a distance L away, to reach your retina is given by:

$$\Delta t_0 = \frac{L}{c}$$

If glass of thickness d and index of refraction n is inserted in the path of the photon, its travel time becomes:

$$\Delta t = t_{\text{in air}} + t_{\text{in glass}} = \frac{L-d}{c} + \frac{d}{c/n}$$

$$= \frac{L+(n-1)d}{c} = \Delta t_0 + \frac{(n-1)d}{c}$$

The time delay is the difference between Δt and Δt_0:

$$t_{\text{delay}} = \Delta t - \Delta t_0 = \frac{(n-1)d}{c}$$

Substitute numerical values and evaluate t_{delay}:

$$t_{\text{delay}} = \frac{(1.5-1)(2\ \text{mm})}{2.998\times10^{8}\ \text{m/s}} \approx \boxed{3\ \text{ps}}$$

20 •• Estimate the number of photons that enter your eye if you look for a tenth of a second at the Sun. What energy is absorbed by your eye during that time, assuming that all the photons are absorbed? The total power output of the Sun is 4.2×10^{26} W.

Picture the Problem The rate at which photons enter your eye is the ratio of power incident on your pupil to the energy per photon. We'll assume that the electromagnetic radiation from the Sun is at 550 nm and that, therefore, its photons have energy (given by $E = hf = hc/\lambda$) of 2.25 eV.

The rate at which photons enter your eye is the ratio of the rate at which energy is incident on your pupil to the energy carried by each photon:

$$\frac{dN}{dt} = \frac{P_{\substack{\text{incident}\\ \text{on pupil}}}}{E_{\text{per photon}}} \quad (1)$$

The intensity of the radiation from the Sun is given by:

$$I_{\text{Sun}} = \frac{P_{\substack{\text{incident}\\ \text{on pupil}}}}{A_{\text{pupil}}} = \frac{P_{\text{Sun}}}{A_{\substack{\text{sphere at Earth's}\\ \text{distance from the Sun}}}}$$

Solving for $P_{\substack{\text{incident}\\ \text{on pupil}}}$ yields:

$$P_{\substack{\text{incident}\\ \text{on pupil}}} = \frac{A_{\text{pupil}}}{A_{\substack{\text{sphere at Earth's}\\ \text{distance from the Sun}}}} P_{\text{Sun}} \quad (2)$$

Substituting in equation (1) yields:

$$\frac{dN}{dt} = \frac{A_{\text{pupil}}}{A_{\substack{\text{sphere at Earth's}\\ \text{distance from the Sun}}}} \frac{P_{\text{Sun}}}{E_{\text{per photon}}}$$

Substitute for the two areas and simplify to obtain:

$$\frac{dN}{dt} = \frac{\frac{1}{4}\pi d_{\text{pupil}}^2}{4\pi R_{\text{Earth-Sun}}^2} \frac{P_{\text{Sun}}}{E_{\text{per photon}}} = \left(\frac{d_{\text{pupil}}}{4R_{\text{Earth-Sun}}}\right)^2 \frac{P_{\text{Sun}}}{E_{\text{per photon}}}$$

Substitute numerical values and evaluate dN/dt:

$$\frac{dN}{dt} = \left(\frac{1\text{ mm}}{4\left(1.50\times10^{11}\text{ m}\right)}\right)^2 \frac{4.2\times10^{26}\text{ W}}{2.25\text{ eV}\times\dfrac{1.602\times10^{-19}\text{ J}}{\text{eV}}} = 3.237\times10^{15}\text{ s}^{-1}$$

or, separating variables and integrating this expression,

$$N = \left(3.237\times10^{15}\text{ s}^{-1}\right)t$$

Evaluating N for $t = 0.1$ s yields:

$$N(0.1\,\text{s}) = (3.237\times10^{15}\ \text{s}^{-1})(0.1\,\text{s}) \approx \boxed{3\times10^{14}\ \text{photons}}$$

The energy deposited, assuming all the photons are absorbed, is the product of the rate at which energy is incident on the pupil and the time during which it is delivered:

$$E = P_{\substack{\text{incident}\\\text{on pupil}}}\,t$$

Substituting for $P_{\substack{\text{incident}\\\text{on pupil}}}$ from equation (2) yields:

$$E = \frac{A_{\text{pupil}}}{A_{\substack{\text{sphere at Earth's}\\\text{distance from the Sun}}}}P_{\text{Sun}}t$$

Substitute for the two areas and simplify to obtain:

$$E = \frac{\frac{1}{4}\pi d_{\text{pupil}}^2}{4\pi R_{\text{Earth-Sun}}^2}P_{\text{Sun}}t = \left(\frac{d_{\text{pupil}}}{4R_{\text{Earth-Sun}}}\right)^2 P_{\text{Sun}}t$$

Substitute numerical values and evaluate E for $t = 0.1$ s:

$$E(0.1\,\text{s}) = \left(\frac{1\,\text{mm}}{4(1.50\times10^{11}\ \text{m})}\right)^2 (4.2\times10^{26}\ \text{W})(0.1\,\text{s}) = 0.1167\ \text{mJ} \approx \boxed{0.1\,\text{mJ}}$$

21 •• Römer was observing the eclipses of Jupiter's moon Io with the hope that they would serve as a highly accurate clock that would be independent of longitude. (Prior to GPS, such a clock was needed for accurate navigation.) Io eclipses (enters the umbra of Jupiter's shadow) every 42.5 h. Assuming an eclipse of Io is observed on Earth on June 1 at midnight when Earth is at location A (as shown in Figure 31-54), predict the expected time of observation of an eclipse one-quarter of a year later when Earth is at location B, assuming (a) the speed of light is infinite and (b) the speed of light is 2.998×10^8 m/s.

Picture the Problem We can use the period of Io's motion and the position of Earth at B to find the number of eclipses of Io during Earth's movement and then use this information to find the number of days before a night-time eclipse. During the 42.5 h between eclipses of Jupiter's moon, Earth moves from A to B, increasing the distance from Jupiter by approximately the distance from Earth to the Sun, making the path for the light longer and introducing a delay in the onset of the eclipse.

(a) Find the time it takes Earth to travel from point A to point B:

$$t_{A\to B}=\frac{T_{\text{earth}}}{4}=\frac{365.24\,\text{d}}{4}\times\frac{24\,\text{h}}{\text{d}}$$
$$=2191.4\,\text{h}$$

Because there are 42.5 h between eclipses of Io, the number of eclipses N occurring in the time it takes for Earth to move from A to B is:

$$N=\frac{t_{A\to B}}{T_{\text{Io}}}=\frac{2191.4\,\text{h}}{42.5\,\text{h}}=51.56$$

Hence, in one-fourth of a year, there will be 51.56 eclipses. Because we want to find the next occurrence that happens in the evening hours, we'll use 52 as the number of eclipses. We'll also assume that Jupiter is visible so that the eclipse of Io can be observed at the time we determine.

Relate the time $t(N)$ at which the Nth eclipse occurs to N and the period T_{Io} of Io:

$$t(N)=NT_{\text{Io}}$$

Evaluate $t(52)$ to obtain:

$$t(52)=(52)\left(42.5\,\text{h}\times\frac{1\,\text{d}}{24\,\text{h}}\right)$$
$$=92.083\,\text{d}$$

Subtract the number of whole days to find the clock time t:

$$t=t(52)-92\,\text{d}=92.083\,\text{d}-92\,\text{d}$$
$$=0.083\,\text{d}\times\frac{24\,\text{h}}{\text{d}}=1.992\,\text{h}$$
$$\approx\boxed{2:00\,\text{a.m.}}$$

Because June, July, and August have 30, 31, and 31 d, respectively, the date is:

$$\boxed{\text{September 1}}$$

(b) Express the time delay Δt in the arrival of light from Io due to Earth's location at B:

$$\Delta t=\frac{r_{\text{earth-sun}}}{c}$$

Substitute numerical values and evaluate Δt:

$$\Delta t=\frac{1.5\times10^{11}\,\text{m}}{2.998\times10^{8}\,\text{m/s}}=500\,\text{s}\times\frac{1\,\text{min}}{60\,\text{s}}$$
$$=8.34\,\text{min}$$

Hence, the eclipse will actually occur at 2:08 a.m., September 1

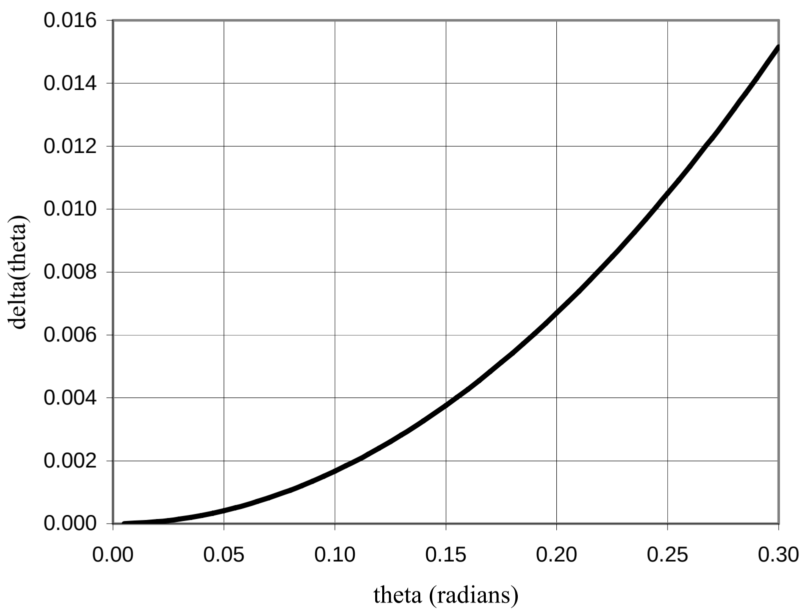
22 •• If the angle of incidence is small enough, the small angle approximation $\sin\theta \approx \theta$ may be used to simplify Snell's law of refraction. Determine the maximum value of the angle that would make the value for the angle differ by no more than one percent from the value for the sine of the angle. (This approximation will be used in connection with image formation by spherical surfaces in Chapter 32.)

Picture the Problem We can express the relative error in using the small angle approximation and then either use 1) trial-and-error methods, 2) a spreadsheet program, or 3) the Solver capability of a scientific calculator to solve the transcendental equation that results from setting the error function equal to 0.01.

Express the relative error δ in using the small angle approximation:

$$\delta(\theta) = \frac{\theta - \sin\theta}{\sin\theta} = \frac{\theta}{\sin\theta} - 1$$

A spreadsheet program was used to plot the following graph of $\delta(\theta)$.



From the graph, we can see that $\delta(\theta) < 1\%$ for $\theta \le 0.24$ radians. In degree measure, $\theta \le \boxed{14°}$

Remarks: Using the Solver program on a TI-85 gave $\theta = 0.244$ radians.

The Speed of Light

23 • Mission Control sends a brief wake-up call to astronauts in a spaceship that is far from Earth. 5.0 s after the call is sent, Mission Control can hear the groans of the astronauts. How far from Earth is the spaceship? (*a*) 7.5×10^8 m, (*b*) 15×10^8 m, (*c*) 30×10^8 m, (*d*) 45×10^8 m, (*e*) The spaceship is on the moon.

Picture the Problem We can use the distance, rate, and time relationship to find the distance to the spaceship.

Relate the distance d to the spaceship to the speed of electromagnetic radiation in a vacuum and to the time for the message to reach the astronauts:

$$d = c\Delta t$$

Noting that the time for the message to reach the astronauts is half the time for Mission Control to hear their response, substitute numerical values and evaluate d:

$$d = \left(2.998\times10^8\ \text{m/s}\right)\left(2.5\,\text{s}\right) = 7.5\times10^8\ \text{m}$$

and $\boxed{(a)}$ is correct.

24 • The distance from a point on the surface of Earth to a point on the surface of the moon is measured by aiming a laser light beam at a reflector on the surface of the moon and measuring the time required for the light to make a round trip. The uncertainty in the measured distance Δx is related to the uncertainty in the measured time Δt by $\Delta x = \frac{1}{2}c\Delta t$. If the time intervals can be measured to ±1.00 ns, (*a*) find the uncertainty of the distance. (*b*) Estimate the percentage uncertainty in the distance.

Picture the Problem We can use the given information that the uncertainty in the measured distance Δx is related to the uncertainty in the time Δt by $\Delta x = c\Delta t$ to evaluate Δx.

(*a*) The uncertainty in the distance is:

$$\Delta x = \tfrac{1}{2}c\Delta t$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \tfrac{1}{2}\left(2.998\times10^8\ \text{m/s}\right)\left(\pm1.00\,\text{ns}\right) = \boxed{\pm15.0\,\text{cm}}$$

(*b*)The percent uncertainty in the distance to the Moon is:

$$\frac{\Delta x_{\text{Earth to Moon}}}{x_{\text{Earth to Moon}}} = \frac{15.0\ \text{cm}}{3.84\times10^{8}\ \text{m}} \approx \boxed{10^{-8}\%}$$

25 •• [SSM] Ole Römer discovered the finiteness of the speed of light by observing Jupiter's moons. Approximately how sensitive would the timing apparatus need to be in order to detect a shift in the predicted time of the moon's eclipses that occur when the moon happens to be at perigee (3.63×10^{5} km) and those that occur when the moon is at apogee (4.06×10^{5} km)? Assume that an instrument should be able to measure to at least one-tenth the magnitude of the effect it is to measure.

Picture the Problem His timing apparatus would need to be sensitive enough to measure the difference in times for light to travel to Earth when the moon is at perigee and at apogee.

The sensitivity of the timing apparatus would need to be one-tenth of the difference in time for light to reach Earth from the two positions of the moon of Jupiter:

$$\text{Sensitivity} = \tfrac{1}{10}\Delta t$$

where Δt is the time required for light to travel between the two positions of the moon.

The time required for light to travel between the two positions of the moon is given by:

$$\Delta t = \frac{d_{\substack{\text{moon}\\ \text{at apogee}}} - d_{\substack{\text{moon}\\ \text{at perigee}}}}{c}$$

Substituting for Δt yields:

$$\text{Sensitivity} = \frac{d_{\substack{\text{moon}\\ \text{at apogee}}} - d_{\substack{\text{moon}\\ \text{at perigee}}}}{10c}$$

Substitute numerical values and evaluate the required sensitivity:

$$\Delta t = \frac{4.06\times10^{5}\ \text{km} - 3.63\times10^{5}\ \text{km}}{(10)(2.998\times10^{8}\ \text{m/s})} = \boxed{14\ \text{ms}}$$

Remarks: Instruments with this sensitivity did not exist in the 17th century.

Reflection and Refraction

26 • Calculate the fraction of light energy reflected from an air–water interface at normal incidence.

Picture the Problem Use the equation relating the intensity of reflected light at normal incidence to the intensity of the incident light and the indices of refraction of the media on either side of the interface.

Express the intensity I of the light reflected from an air-water interface at normal incidence in terms of the indices of refraction and the intensity I_0 of the incident light:

$$I=\left(\frac{n_{\text{air}}-n_{\text{water}}}{n_{\text{air}}+n_{\text{water}}}\right)^2 I_0$$

Solve for the ratio I/I_0:

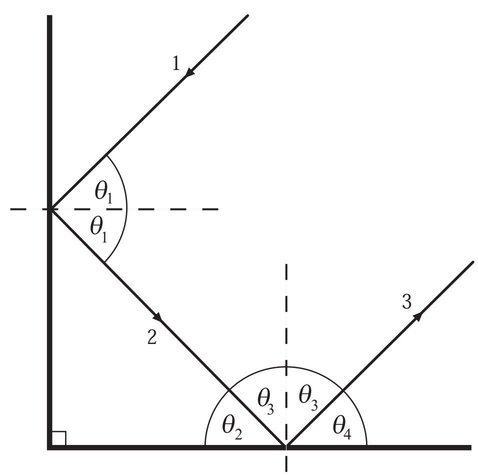
$$\frac{I}{I_0}=\left(\frac{n_{\text{air}}-n_{\text{water}}}{n_{\text{air}}+n_{\text{water}}}\right)^2$$

Substitute numerical values and evaluate I/I_0:

$$\frac{I}{I_0}=\left(\frac{1.00-1.33}{1.00+1.33}\right)^2=\boxed{2.0\%}$$

27 • A ray of light is incident on one of a pair of mirrors set at right angles to each A ray of light is incident on one of two mirrors that are set at right angles to each other. The plane of incidence is perpendicular to both mirrors. Show that after reflecting from each mirror, the ray will emerge traveling in the direction opposite to the incident direction, regardless of the angle of incidence.

Picture the Problem The diagram shows ray 1 incident on the vertical surface at an angle θ_1, reflected as ray 2, and incident on the horizontal surface at an angle of incidence θ_3. We'll prove that rays 1 and 3 are parallel by showing that $\theta_1 = \theta_4$, i.e., by showing that they make equal angles with the horizontal. Note that the law of reflection has been used in identifying equal angles of incidence and reflection.



We know that the angles of the right triangle formed by ray 2 and the two mirror surfaces add up to 180°:

$$\theta_2+90°+(90°-\theta_1)=180°$$

or

$$\theta_1=\theta_2$$

The sum of θ_2 and θ_3 is 90°:

$$\theta_3=90°-\theta_2$$

Because $\theta_1=\theta_2$:

$$\theta_3=90°-\theta_1$$

The sum of θ_4 and θ_3 is 90°:

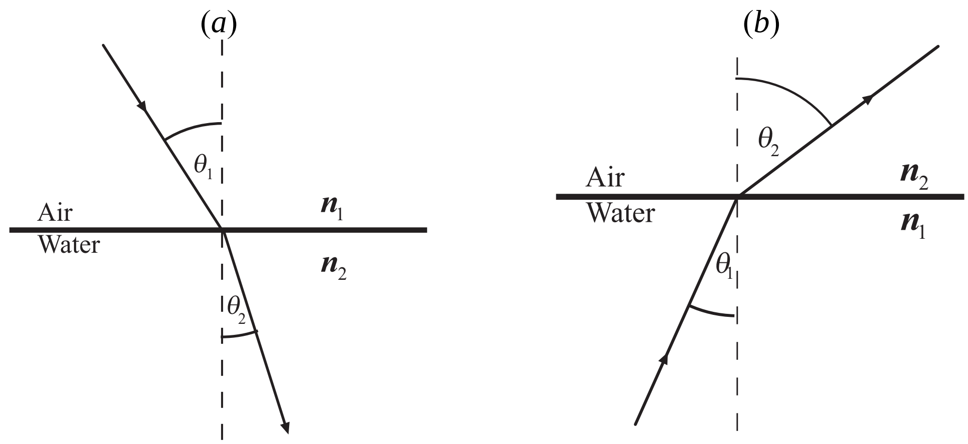
$$\theta_3+\theta_4=90°$$

Substitute for θ_3 to obtain:

$$(90° - \theta_1) + \theta_4 = 90° \Rightarrow \theta_1 = \boxed{\theta_4}$$

28 •• (*a*) A ray of light in air is incident on an air–water interface. Using a **spreadsheet** or graphing program, plot the angle of refraction as a function of the angle of incidence from 0º to 90º. (*b*) Repeat Part (*a*), but for a ray of light in water that is incident on a water–air interface. [For Part (*b*), there is no reflected ray for angles of incidence that are greater than the critical angle.]

Picture the Problem Diagrams showing the light rays for the two cases are shown below. In (*a*) the light travels from air into water and in (*b*) it travels from water into air.



(*a*) Apply Snell's law to the air-water interface to obtain:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

where the angles of incidence and refraction are θ_1 and θ_2, respectively.

Solving for θ_2 yields:

$$\theta_2 = \sin^{-1}\left(\frac{n_1}{n_2}\sin\theta_1\right)$$

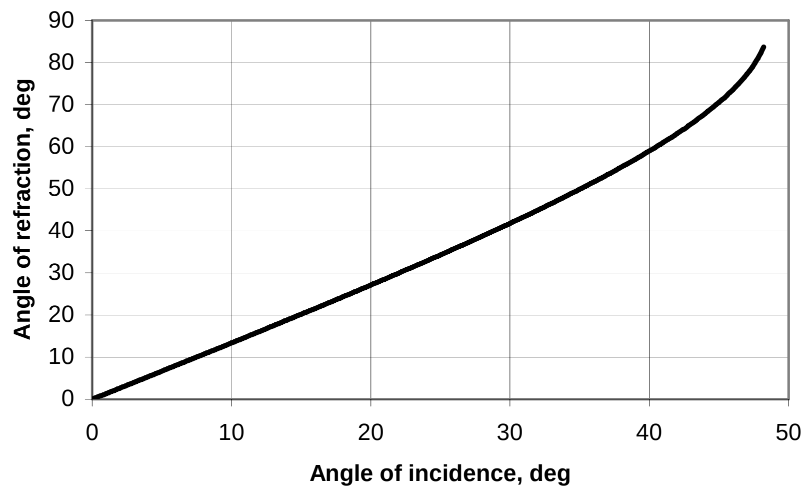
A spreadsheet program to graph θ_2 as a function of θ_1 is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
B1	1	n_1
B2	1.33333	n_2
A6	0	θ_1 (deg)
A7	A6 + 5	$\theta_1 + \Delta\theta$
B6	A6*PI()/180	$\theta_1 \times \dfrac{\pi}{180}$
C6	ASIN(($B$1/$B$2)*SIN(B6))	$\sin^{-1}\left(\dfrac{n_1}{n_2}\sin\theta_1\right)$
D6	C6*180/PI()	$\theta_2 \times \dfrac{180}{\pi}$

	A	B	C	D
1	n_1=	1		
2	n_2=	1.33333		
3				
4	θ_1	θ_1	θ_2	θ_2
5	(deg)	(rad)	(rad)	(deg)
6	0	0.00	0.000	0.00
7	1	0.02	0.013	0.75
8	2	0.03	0.026	1.50
9	3	0.05	0.039	2.25
21	87	1.52	0.847	48.50
22	88	1.54	0.847	48.55
23	89	1.55	0.848	48.58
24	90	1.57	0.848	48.59

A graph of θ_2 as a function of θ_1 follows:

(b) Change the contents of cell B1 to 1.33333 and the contents of cell B2 to 1 to obtain the following graph:



Note that as the angle of incidence approaches the critical angle for a water-air interface (48.6°), the angle of refraction approaches 90°.

29 •• The red light from a helium-neon laser has a wavelength of 632.8 nm in air. Find the (a) speed, (b) wavelength, and (c) frequency of helium-neon laser light in air, water, and glass. (The glass has an index of refraction equal to 1.50.)

Picture the Problem We can use the definition of the index of refraction to find the speed of light in the three media. The wavelength of the light in each medium is its wavelength in air divided by the index of refraction of the medium. The frequency of the helium-neon laser light is the same in all media and is equal to its value in air. The wavelength of helium-neon laser light in air is 632.8 nm.

The speed of light in a medium whose index of refraction is n is given by:

$$v = \frac{c}{n} \quad (1)$$

The wavelength of light in a medium whose index of refraction is n is given by:

$$\lambda_{n} = \frac{\lambda_{air}}{n} \quad (2)$$

The frequency of the light is equal to its frequency in air independently of the medium in which the light is propagating:

$$f = \frac{c}{\lambda} = \frac{2.998\times10^{8}\ \text{m/s}}{632.8\ \text{nm}} = \boxed{4.74\times10^{14}\ \text{Hz}}$$

Substitute numerical values in equation (1) and evaluate v_{water}:

$$v_{water} = \frac{2.998\times10^{8}\ \text{m/s}}{1.33} = \boxed{2.25\times10^{8}\ \text{m/s}}$$

Substitute numerical values in equation (2) and evaluate λ_{water}:

$$\lambda_{water} = \frac{632.8\ \text{nm}}{1.33} = \boxed{476\ \text{nm}}$$

The other speeds and wavelengths are found similarly and are summarized in the following table:

	(*a*) speed (m/s)	(*b*) wavelength (nm)	(*c*) frequency (Hz)
Air	$\boxed{3.00\times10^{8}}$	$\boxed{633}$	$\boxed{4.74\times10^{14}}$
Water	$\boxed{2.25\times10^{8}}$	$\boxed{476}$	$\boxed{4.74\times10^{14}}$
glass	$\boxed{2.00\times10^{8}}$	$\boxed{422}$	$\boxed{4.74\times10^{14}}$

30 •• The index of refraction for silicate flint glass is 1.66 for violet light that has a wavelength in air equal to 400 nm and 1.61 for red light that has a wavelength in air equal to 700 nm. A ray of 700-nm–wavelength red light and a ray of 400-nm-wavelength violet light both have angles of refraction equal to 30º upon entering the glass from air. (*a*) Which is greater, the angle of incidence of the ray of red light or the angle of incidence of the ray of violet light? Explain your answer. (*b*) What is the difference between the angles of incidence of the two rays?

Picture the Problem Let the subscript 1 refer to the air and the subscript 2 to the silicate glass and apply Snell's law to the air-glass interface.

(*a*) Because the index of refraction for violet light is larger than that of red light, for a given incident angle violet light would refract more than red light. Thus to exhibit the same refraction angle, violet light would require an angle of incidence larger than that of red light.

(*b*) Express the difference in their angles of incidence:

$$\Delta\theta = \theta_{1,\text{violet}} - \theta_{1,\text{red}} \qquad (1)$$

Apply Snell's law to the air-glass interface to obtain:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

Solving for θ_1 yields:

$$\theta_1 = \sin^{-1}\left(\frac{n_2}{n_1}\sin\theta_2\right)$$

Substitute for $\theta_{1,\text{violet}}$ and $\theta_{1,\text{red}}$ in equation (1) to obtain:

$$\Delta\theta = \sin^{-1}\left(\frac{n_{\text{violet}}}{n_{\text{air}}}\sin\theta_{2,\text{ violet}}\right) - \sin^{-1}\left(\frac{n_{\text{red}}}{n_{\text{air}}}\sin\theta_{2,\text{ red}}\right)$$

For $\theta_{2,\text{ violet}} = \theta_{2,\text{ red}} = 30°$:

$$\Delta\theta = \sin^{-1}\left(\frac{n_{\text{violet}}}{n_{\text{air}}}\sin 30°\right) - \sin^{-1}\left(\frac{n_{\text{red}}}{n_{\text{air}}}\sin 30°\right) = \sin^{-1}\left(\frac{n_{\text{violet}}}{2n_{\text{air}}}\right) - \sin^{-1}\left(\frac{n_{\text{red}}}{2n_{\text{air}}}\right)$$

Substitute numerical values and evaluate $\Delta\theta$:

$$\Delta\theta = \sin^{-1}\left(\frac{1.66}{2(1.00)}\right) - \sin^{-1}\left(\frac{1.61}{2(1.00)}\right) = 56.10° - 53.61° = \boxed{2.49°}$$

Remarks: Note that $\Delta\theta$ is positive. This means that the angle for violet light is greater than that for red light and confirms our answer in Part (*a*).

31 •• [SSM] A slab of glass that has an index of refraction of 1.50 is submerged in water that has an index of refraction of 1.33. Light in the water is incident on the glass. Find the angle of refraction if the angle of incidence is (*a*) 60º, (*b*) 45º, and (*c*) 30º.

Picture the Problem Let the subscript 1 refer to the water and the subscript 2 to the glass and apply Snell's law to the water-glass interface.

Apply Snell's law to the water-glass interface to obtain:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

Solving for θ_2 yields:

$$\theta_2 = \sin^{-1}\left(\frac{n_1}{n_2}\sin\theta_1\right)$$

(*a*) Evaluate θ_2 for $\theta_1 = 60°$:

$$\theta_2 = \sin^{-1}\left(\frac{1.33}{1.50}\sin 60°\right) = \boxed{50°}$$

(*b*) Evaluate θ_2 for $\theta_1 = 45°$:

$$\theta_2 = \sin^{-1}\left(\frac{1.33}{1.50}\sin 45°\right) = \boxed{39°}$$

(*c*) Evaluate θ_2 for $\theta_1 = 30°$:

$$\theta_2 = \sin^{-1}\left(\frac{1.33}{1.50}\sin 30°\right) = \boxed{26°}$$

32 •• Repeat Problem 31 for a beam of light initially in the glass that is incident on the glass–water interface at the same angles.

Picture the Problem Let the subscript 1 refer to the glass and the subscript 2 to the water and apply Snell's law to the glass-water interface.

Apply Snell's law to the water-glass interface to obtain:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

Solving for θ_2 yields:

$$\theta_2 = \sin^{-1}\left(\frac{n_1}{n_2}\sin\theta_1\right)$$

(*a*) Evaluate θ_2 for $\theta_1 = 60°$:

$$\theta_2 = \sin^{-1}\left(\frac{1.50}{1.33}\sin 60°\right) = \boxed{78°}$$

(*b*) Evaluate θ_2 for $\theta_1 = 45°$:

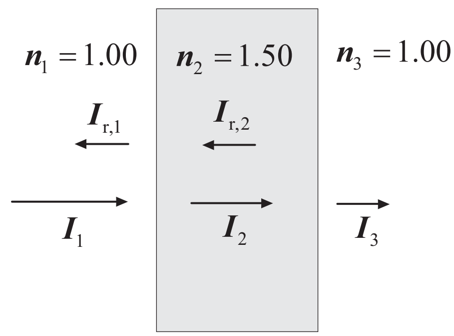
$$\theta_2 = \sin^{-1}\left(\frac{1.50}{1.33}\sin 45°\right) = \boxed{53°}$$

(*c*) Evaluate θ_2 for $\theta_1 = 30°$:

$$\theta_2 = \sin^{-1}\left(\frac{1.50}{1.33}\sin 30°\right) = \boxed{34°}$$

33 •• A beam of light in air strikes a glass slab at normal incidence. The glass slab has an index of refraction of 1.50. (*a*) Approximately what percentage of the incident light intensity is transmitted through the slab (in one side and out the other)? (*b*) Repeat Part (*a*) if the glass slab is immersed in water.

Picture the Problem Let the subscript 1 refer to the medium to the left (air) of the first interface, the subscript 2 to glass, and the subscript 3 to the medium (air) to the right of the second interface. Apply the equation relating the intensity of reflected light at normal incidence to the intensity of the incident light and the indices of refraction of the media on either side of the interface to both interfaces. We'll neglect multiple reflections at glass-air interfaces.



(*a*) Express the intensity of the transmitted light in the second medium:

$$I_2 = I_1 - I_{r,1} = I_1 - \left(\frac{n_1 - n_2}{n_1 + n_2}\right)^2 I_1$$

$$= I_1\left[1 - \left(\frac{n_1 - n_2}{n_1 + n_2}\right)^2\right]$$

Express the intensity of the transmitted light in the third medium:

$$I_3 = I_2 - I_{r,2} = I_2 - \left(\frac{n_2 - n_3}{n_2 + n_3}\right)^2 I_2$$

$$= I_2\left[1 - \left(\frac{n_2 - n_3}{n_2 + n_3}\right)^2\right]$$

Substitute for I_2 to obtain:

$$I_3 = I_1\left[1 - \left(\frac{n_1 - n_2}{n_1 + n_2}\right)^2\right]\left[1 - \left(\frac{n_2 - n_3}{n_2 + n_3}\right)^2\right]$$

Solve for the ratio I_3/I_1 to obtain:

$$\frac{I_3}{I_1} = \left[1 - \left(\frac{n_1 - n_2}{n_1 + n_2}\right)^2\right]\left[1 - \left(\frac{n_2 - n_3}{n_2 + n_3}\right)^2\right]$$

Substitute numerical values and evaluate I_3/I_1:

$$\frac{I_3}{I_1} = \left[1 - \left(\frac{1.00 - 1.50}{1.00 + 1.50}\right)^2\right]\left[1 - \left(\frac{1.50 - 1.00}{1.50 + 1.00}\right)^2\right] = \boxed{92\%}$$

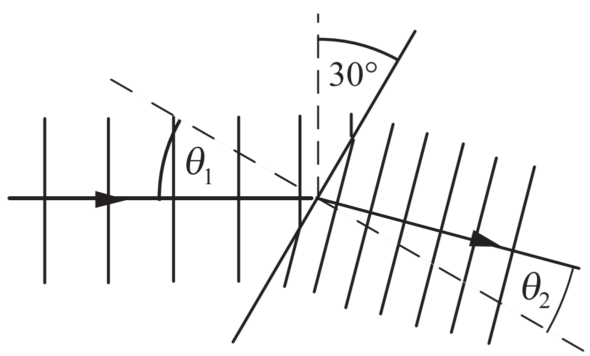
(*b*) With $n_1 = n_3 = 1.33$:

$$\frac{I_3}{I_1} = \left[1 - \left(\frac{1.33 - 1.50}{1.33 + 1.50}\right)^2\right]\left[1 - \left(\frac{1.50 - 1.33}{1.50 + 1.33}\right)^2\right] = \boxed{99\%}$$

34 •• This problem is a refraction analogy. A band is marching down a football field with a constant speed v_1. About midfield, the band comes to a section of muddy ground that has a sharp boundary making an angle of 30º with the 50-yd line, as shown in Figure 31-55. In the mud, each marcher moves at a speed equal to $\frac{1}{2}v_1$ in a direction perpendicular to the row of markers they are in. (*a*) Diagram how each line of marchers is bent as it encounters the muddy section of the field so that the band is eventually marching in a different direction. Indicate the original direction by a ray and the final direction by a second ray. (*b*) Find the angles between these rays and the line normal to the boundary. Is their direction of motion "bent" toward the normal or away from it? Explain your answer in terms of refraction.

Picture the Problem We can apply Snell's law to find the angle of refraction of the line of marchers as they enter the muddy section of the field

(*a*)



(*b*) Apply Snell's law at the interface to obtain:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

Solving for θ_2 yields:

$$\theta_2 = \sin^{-1}\left[\frac{n_1}{n_2}\sin\theta_1\right]$$

The ratio of the indices of refraction is the reciprocal of the ratio of the speeds of the marchers in the two media:

$$\frac{n_1}{n_2} = \frac{\frac{v}{v_1}}{\frac{v}{v_2}} = \frac{v_2}{v_1} = \frac{\frac{1}{2}v_1}{v_1} = \frac{1}{2}$$

Because the left and right sides of the 30° angle and θ_1 are mutually perpendicular, θ_1 = 30°. Substitute numerical values and evaluate θ_2:

$$\theta_2 = \sin^{-1}\left[\tfrac{1}{2}\sin 30°\right] = \boxed{14°}$$

As the line enters the muddy field, its speed is reduced by half and the direction of the forward motion of the line is changed. In this case, the forward motion in the muddy field makes an angle θ_2 with respect to the normal to the boundary line. Note that the separation between successive lines in the muddy field is half that in the dry field.

35 •• [SSM] In Figure 31-56, light is initially in a medium that has an index of refraction n_1. It is incident at angle θ_1 on the surface of a liquid that has an index of refraction n_2. The light passes through the layer of liquid and enters glass that has an index of refraction n_3. If θ_3 is the angle of refraction in the glass, show that $n_1 \sin \theta_1 = n_3 \sin \theta_3$. That is, show that the second medium can be neglected when finding the angle of refraction in the third medium.

Picture the Problem We can apply Snell's law consecutively, first to the n_1-n_2 interface and then to the n_2-n_3 interface.

Apply Snell's law to the n_1-n_2 interface:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

Apply Snell's law to the n_2-n_3 interface:

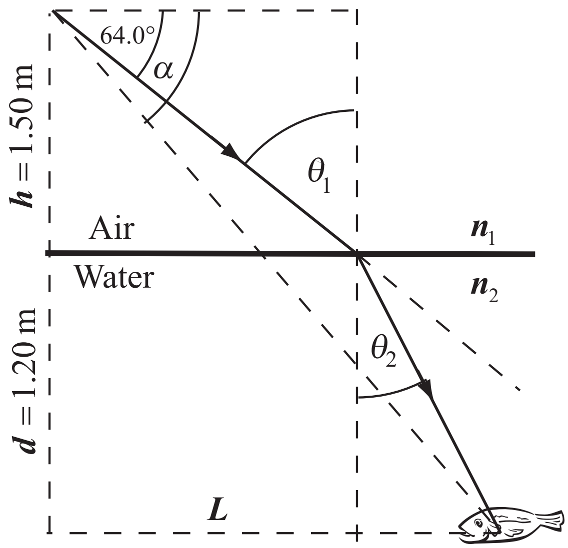
$$n_2 \sin\theta_2 = n_3 \sin\theta_3$$

Equate the two expressions for $n_2 \sin\theta_2$ to obtain:

$$\boxed{n_1 \sin\theta_1 = n_3 \sin\theta_3}$$

36 •• On a safari, you are spear fishing while wading in a river. You observe a fish gliding by you. If your line of sight to the fish is 64.0° degrees below the horizontal in air, and assuming the spear follows a straight-line path through the air and water after it is released, determine the angle below the horizontal that you should aim your spear gun in order to catch dinner. Assume the spear gun barrel is 1.50 m above the water surface, the fish is 1.20 m below the surface, and the spear travels in a straight line all the way to the fish.

Picture the Problem The following pictorial representation summarizes the information given in the problem statement. We can use the geometry of the diagram and apply Snell's law at the air-water interface to find the aiming angle α.



Use the pictorial representation to express the aiming angle α:

$$\alpha = \tan^{-1}\left[\frac{h+d}{L+\ell}\right]$$

Referring to the diagram, note that:

$L = h\tan\theta_1$ and $\ell = d\tan\theta_2$

Substituting for L and ℓ yields:

$$\alpha = \tan^{-1}\left[\frac{h+d}{h\tan\theta_1 + d\tan\theta_2}\right]$$

Apply Snell's law at the air-water interface to obtain:

$$n_1\sin\theta_1 = n_2\sin\theta_2$$

Solving for θ_2 yields:

$$\theta_2 = \sin^{-1}\left[\frac{n_1}{n_2}\sin\theta_1\right]$$

Substitute for θ_2 to obtain:

$$\alpha = \tan^{-1}\left[\frac{h+d}{h\tan\theta_1 + d\tan\left(\sin^{-1}\left[\frac{n_1}{n_2}\sin\theta_1\right]\right)}\right]$$

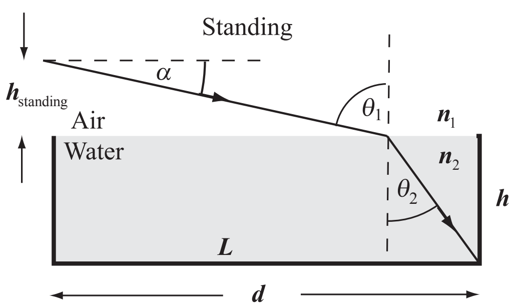
Noting that θ_1 is the complement of 64.0°, substitute numerical values and evaluate α:

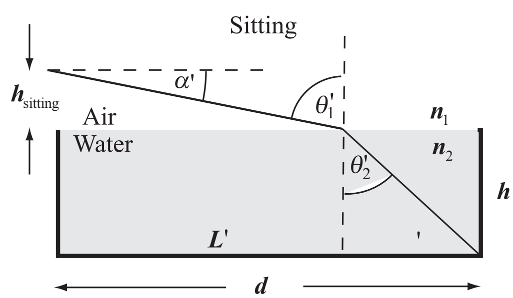
$$\alpha = \tan^{-1}\left[\frac{1.50\text{ m} + 1.20\text{ m}}{(1.50\text{ m})\tan 26.0° + (1.20\text{ m})\tan\left(\sin^{-1}\left[\frac{1.00}{1.33}\sin 26.0°\right]\right)}\right] = \boxed{66.9°}$$

That is, you should aim 66.9° below the horizontal.

37 ••• You are standing on the edge of a swimming pool and looking directly across at the opposite side. You notice that the bottom edge of the opposite side of the pool appears to be at an angle of 28° degrees below the horizontal. However, when you sit on the pool edge, the bottom edge of the opposite side of the pool appears to be at an angle of only 14° below the horizontal. Use these observations to determine the width and depth of the pool. *Hint: You will need to estimate the height of your eyes above the surface of the water when standing and sitting.*

Picture the Problem The following diagrams represent the situations when you are standing on the edge of the pool (the diagram to the left) and when you are sitting on the edge of the pool (the diagram to the right). We can use Snell's law and the geometry of the pool to determine the width and depth of the pool.





Use the fact that angles α and θ_1 are complementary, as are α' and θ_1' to determine θ_1 and θ_1':

$$\theta_1 = 90° - \alpha = 90° - 28° = 62°$$

and

$$\theta_1' = 90° - \alpha' = 90° - 14° = 76°$$

Express the distances L and L' in terms of θ_1 and θ_1':

$$L = h_{\text{standing}} \tan\theta_1$$

and

$$L' = h_{\text{sitting}} \tan\theta_1'$$

Assuming that your eyes are 1.7 m above the level of the water when you are standing and 0.7 m above the water when you are sitting, evaluate L and L':

$$L = (1.7\text{ m})\tan 62° = 3.197\text{ m}$$
and
$$L' = (0.7\text{ m})\tan 76° = 2.808\text{ m}$$

Referring to the pictorial representations, note that:

$$\tan\theta_2 = \frac{\ell}{h} = \frac{d-L}{h} \qquad (1)$$
and
$$\tan\theta_2' = \frac{\ell'}{h} = \frac{d-L'}{h}$$

Divide the first of these equations by the second to obtain:

$$\frac{\tan\theta_2}{\tan\theta_2'} = \frac{d-L}{d-L'}$$

Solving for d yields:

$$d = \frac{L'\tan\theta_2 - L\tan\theta_2'}{\tan\theta_2 - \tan\theta_2'} \qquad (2)$$

Apply Snell's law to the air-water interface when you are standing:

$$\theta_2 = \sin^{-1}\left[\frac{n_1}{n_2}\sin\theta_1\right]$$

Substitute numerical values and evaluate θ_2:

$$\theta_2 = \sin^{-1}\left[\frac{1.00}{1.33}\sin 62°\right] = 41.60°$$

Apply Snell's law to the air-water interface when you are sitting:

$$\theta_2' = \sin^{-1}\left[\frac{n_1}{n_2}\sin\theta_1'\right]$$

Substitute numerical values and evaluate θ_2':

$$\theta_2' = \sin^{-1}\left[\frac{1.00}{1.33}\sin 76°\right] = 46.85°$$

Substitute numerical values in equation (2) and evaluate d:

$$d = \frac{(2.808\text{ m})\tan 41.60° - (3.197\text{ m})\tan 46.85°}{\tan 41.60° - \tan 46.85°} = 5.130\text{ m} = \boxed{5.1\text{ m wide}}$$

Solving equation (1) for h yields:

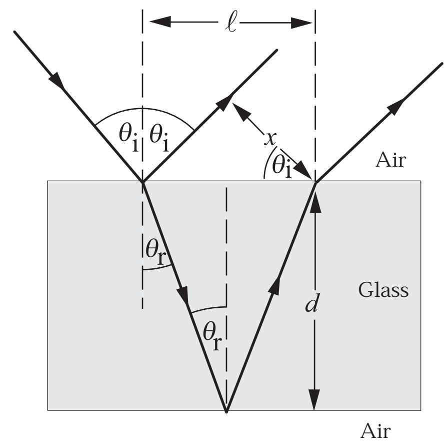
$$h = \frac{d-L}{\tan\theta_2}$$

Substitute numerical values and evaluate h:

$$h = \frac{5.130\text{ m} - 3.197\text{ m}}{\tan 41.60°} = \boxed{2.2\text{ m deep}}$$

38 ••• Figure 31-57 shows a beam of light incident on a glass plate of thickness *d* and index of refraction *n*. (*a*) Find the angle of incidence so that the separation *b* between the ray reflected from the top surface and the ray reflected from the bottom surface and exiting the top surface is a maximum. (*b*) What is this angle of incidence if the index of refraction of the glass is 1.60? (*c*) What is the separation of the two beams if the thickness of the glass plate is 4.0 cm?

Picture the Problem Let x be the perpendicular separation between the two rays and let ℓ be the separation between the points of emergence of the two rays on the glass surface. We can use the geometry of the refracted and reflected rays to express x as a function of ℓ, d, θ_r, and θ_i. Setting the derivative of the resulting equation equal to zero will yield the value of θ_i that maximizes x.



(*a*) Express ℓ in terms of d and the angle of refraction θ_r:

$$\ell = 2d\tan\theta_r$$

Express x as a function of ℓ, d, θ_r, and θ_i:

$$x = 2d\tan\theta_r\cos\theta_i$$

Differentiate x with respect to θ_i:

$$\frac{dx}{d\theta_i} = 2d\frac{d}{d\theta_i}\left(\tan\theta_r\cos\theta_i\right) = 2d\left(-\tan\theta_r\sin\theta_i + \sec^2\theta_r\cos\theta_i\frac{d\theta_r}{d\theta_i}\right) \quad (1)$$

Apply Snell's law to the air-glass interface:

$$n_1\sin\theta_i = n_2\sin\theta_r \quad (2)$$

or, because $n_1 = 1$ and $n_2 = n$,

$$\sin\theta_i = n\sin\theta_r$$

Differentiate implicitly with respect to θ_i to obtain:

$$\cos\theta_i d\theta_i = n\cos\theta_r d\theta_r$$

or

$$\frac{d\theta_r}{d\theta_i} = \frac{1}{n}\frac{\cos\theta_i}{\cos\theta_r}$$

Substitute in equation (1) to obtain:

$$\frac{dx}{d\theta_\mathrm{i}} = 2d\left(-\frac{\sin\theta_\mathrm{r}}{\cos\theta_\mathrm{r}}\sin\theta_\mathrm{i} + \frac{1}{n}\frac{\cos\theta_\mathrm{i}}{\cos^2\theta_\mathrm{r}}\frac{\cos\theta_\mathrm{i}}{\cos\theta_\mathrm{r}}\right) = 2d\left(\frac{1}{n}\frac{\cos^2\theta_\mathrm{i}}{\cos^3\theta_\mathrm{r}} - \frac{\sin\theta_\mathrm{r}\sin\theta_\mathrm{i}}{\cos\theta_\mathrm{r}}\right)$$

Substitute $1-\sin^2\theta_\mathrm{i}$ for $\cos^2\theta_\mathrm{i}$ and $\frac{1}{n}\sin\theta_\mathrm{i}$ for $\sin\theta_\mathrm{r}$ to obtain:

$$\frac{dx}{d\theta_\mathrm{i}} = 2d\left(\frac{1-\sin^2\theta_\mathrm{i}}{n\cos^3\theta_\mathrm{r}} - \frac{\sin^2\theta_\mathrm{i}}{n\cos\theta_\mathrm{r}}\right)$$

Multiply the second term in parentheses by $\cos^2\theta_\mathrm{r}/\cos^2\theta_\mathrm{r}$ and simplify to obtain:

$$\frac{dx}{d\theta_\mathrm{i}} = 2d\left(\frac{1-\sin^2\theta_\mathrm{i}}{n\cos^3\theta_\mathrm{r}} - \frac{\sin^2\theta_\mathrm{i}\cos^2\theta_\mathrm{r}}{n\cos^3\theta_\mathrm{r}}\right) = \frac{2d}{n\cos^3\theta_\mathrm{r}}\left(1-\sin^2\theta_\mathrm{i} - \sin^2\theta_\mathrm{i}\cos^2\theta_\mathrm{r}\right)$$

Substitute $1-\sin^2\theta_\mathrm{r}$ for $\cos^2\theta_\mathrm{r}$:

$$\frac{dx}{d\theta_\mathrm{i}} = \frac{2d}{n\cos^3\theta_\mathrm{r}}\left[1-\sin^2\theta_\mathrm{i} - \sin^2\theta_\mathrm{i}\left(1-\sin^2\theta_\mathrm{r}\right)\right]$$

Substitute $\frac{1}{n}\sin\theta_\mathrm{i}$ for $\sin\theta_\mathrm{r}$ to obtain:

$$\frac{dx}{d\theta_\mathrm{i}} = \frac{2d}{n\cos^3\theta_\mathrm{r}}\left[1-\sin^2\theta_\mathrm{i} - \sin^2\theta_\mathrm{i}\left(1-\frac{1}{n^2}\sin^2\theta_\mathrm{i}\right)\right]$$

Factor out $1/n^2$, simplify, and set equal to zero to obtain:

$$\frac{dx}{d\theta_\mathrm{i}} = \frac{2d}{n^3\cos^3\theta_\mathrm{r}}\left[\sin^4\theta_\mathrm{i} - 2n^2\sin^2\theta_\mathrm{i} + n^2\right] = 0 \text{ for extrema}$$

If $dx/d\theta_\mathrm{i} = 0$, then it must be true that:

$$\sin^4\theta_\mathrm{i} - 2n^2\sin^2\theta_\mathrm{i} + n^2 = 0$$

Solve this quartic equation for θ_i to obtain:

$$\theta_\mathrm{i} = \boxed{\sin^{-1}\left(n\sqrt{1-\sqrt{1-\frac{1}{n^2}}}\right)}$$

(*b*) Evaluate θ_i for $n = 1.60$:

$$\theta_i = \sin^{-1}\left(1.6\sqrt{1-\sqrt{1-\frac{1}{(1.60)^2}}}\right) = \boxed{48.5°}$$

(*c*) In (*a*) we showed that:

$$x = 2d\tan\theta_r\cos\theta_i$$

Solve equation (2) for θ_r:

$$\theta_r = \sin^{-1}\left(\frac{n_1}{n_2}\sin\theta_i\right)$$

Substitute numerical values and evaluate θ_r:

$$\theta_r = \sin^{-1}\left(\frac{1}{1.60}\sin 48.5°\right) = 27.9°$$

Substitute numerical values and evaluate *x*:

$$\boldsymbol{x} = 2(4.0\,\text{cm})\tan 27.9°\cos 48.5° = \boxed{2.8\,\text{cm}}$$

Total Internal Reflection

39 • **[SSM]** What is the critical angle for light traveling in water that is incident on a water–air interface?

Picture the Problem Let the subscript 1 refer to the water and the subscript 2 to the air and use Snell's law under total internal reflection conditions.

Use Snell's law to obtain:

$$n_1\sin\theta_1 = n_2\sin\theta_2$$

When there is total internal reflection:

$$\theta_1 = \theta_c \text{ and } \theta_2 = 90°$$

Substitute to obtain:

$$n_1\sin\theta_c = n_2\sin 90° = n_2$$

Solving for θ_c yields:

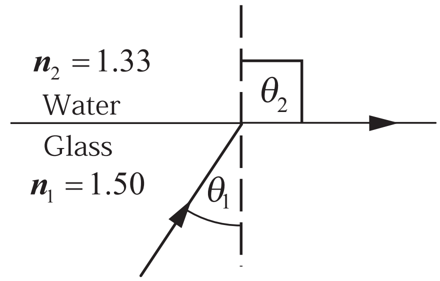
$$\theta_c = \sin^{-1}\left(\frac{n_2}{n_1}\right)$$

Substitute numerical values and evaluate θ_c:

$$\theta_c = \sin^{-1}\left(\frac{1.00}{1.33}\right) = \boxed{48.8°}$$

40 • A glass surface ($n = 1.50$) has a layer of water ($n = 1.33$) on it. Light in the glass is incident on the glass–water interface. Find the critical angle for total internal reflection.

Picture the Problem Let the index of refraction of glass be represented by n_1 and the index of refraction of water by n_2 and apply Snell's law to the glass-water interface under total internal reflection conditions.



Apply Snell's law to the glass-water interface:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

At the critical angle, $\theta_1 = \theta_c$ and $\theta_2 = 90°$:

$$n_1 \sin\theta_c = n_2 \sin 90°$$

Solve for θ_c:

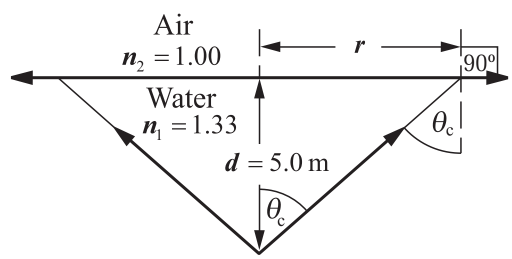
$$\theta_c = \sin^{-1}\left[\frac{n_2}{n_1}\sin 90°\right]$$

Substitute numerical values and evaluate θ_c:

$$\theta_c = \sin^{-1}\left[\frac{1.33}{1.50}\sin 90°\right] = \boxed{62.5°}$$

41 • A point source of light is located 5.0 m below the surface of a large pool of water. Find the area of the largest circle on the pool's surface through which light coming directly from the source can emerge.

Picture the Problem We can apply Snell's law to the water-air interface to express the critical angle θ_c in terms of the indices of refraction of water (n_1) and air (n_2) and then relate the radius of the circle to the depth d of the point source and θ_c.



Express the area of the circle whose radius is r:

$$A = \pi r^2$$

Relate the radius of the circle to the depth d of the point source and the critical angle θ_c:

$$r = d\tan\theta_c$$

Apply Snell's law to the water-air interface to obtain:

$$n_1 \sin\theta_c = n_2 \sin 90° = n_2$$

Solving for θ_c yields:

$$\theta_c = \sin^{-1}\left(\frac{n_2}{n_1}\right)$$

Substitute for r and θ_c to obtain:

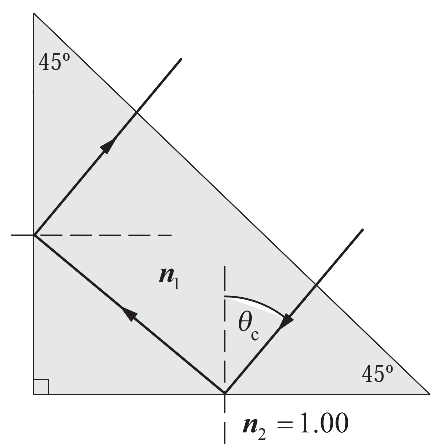
$$A = \pi[d\tan\theta_c]^2 = \pi\left[d\tan\left(\sin^{-1}\left\{\frac{n_2}{n_1}\right\}\right)\right]^2$$

Substitute numerical values and evaluate A:

$$A = \pi\left[(5.0\text{ m})\tan\left(\sin^{-1}\left\{\frac{1}{1.33}\right\}\right)\right]^2 = \boxed{1.0\times10^2\text{ m}^2}$$

42 •• Light traveling in air strikes the largest face of an isosceles-right-triangle prism at normal incidence. What is the speed of light in this prism if the prism is just barely able to produce total internal reflection?

Picture the Problem We can use the definition of the index of refraction to express the speed of light in the prism in terms of the index of refraction n_1 of the prism. The application of Snell's law at the prism-air interface will allow us to relate the index of refraction of the prism to the critical angle for total internal reflection. Finally, we can use the geometry of the isosceles-right-triangle prism to conclude that $\theta_c = 45°$.



Express the speed of light v in the prism in terms of its index of refraction n_1:

$$v = \frac{c}{n_1}$$

Apply Snell's law to the prism-air interface to obtain:

$$n_1\sin\theta_c = n_2\sin 90° = 1$$

Solving for n_1 yields:

$$n_1 = \frac{1}{\sin\theta_c}$$

Substitute for n_1 and simplify to obtain:

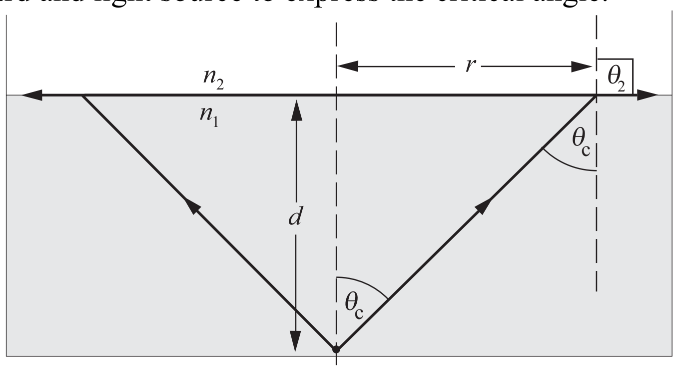
$$v = c\sin\theta_c$$

Substitute numerical values and evaluate v:

$$v = \left(2.998\times10^8\ \text{m/s}\right)\sin 45° = \boxed{2.1\times10^8\ \text{m/s}}$$

43 •• A point source of light is located at the bottom of a steel tank, and an opaque circular card of radius 6.00 cm is placed horizontally over it. A transparent fluid is gently added to the tank so that the card floats on the fluid surface with its center directly above the light source. No light is seen by an observer above the surface until the fluid is 5.00 cm deep. What is the index of refraction of the fluid?

Picture the Problem The observer above the surface of the fluid will not see any light until the angle of incidence of the light at the fluid-air interface is less than or equal to the critical angle for the two media. We can use Snell's law to express the index of refraction of the fluid in terms of the critical angle and use the geometry of card and light source to express the critical angle.



Apply Snell's law to the fluid-air interface to obtain:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

Light is seen by the observer when $\theta_1 = \theta_c$ and $\theta_2 = 90°$:

$$n_1 \sin\theta_c = n_2 \sin 90° = n_2$$

Because the medium above the interface is air, $n_2 = 1$. Solve for n_1 to obtain:

$$n_1 = \frac{1}{\sin\theta_c}$$

From the geometry of the diagram:

$$\tan\theta_c = \frac{r}{d} \Rightarrow \theta_c = \tan^{-1}\left(\frac{r}{d}\right)$$

Substitute for θ_c to obtain:

$$n_1 = \frac{1}{\sin\left[\tan^{-1}\left(\frac{r}{d}\right)\right]}$$

Substitute numerical values and evaluate n_1:

$$n_1 = \frac{1}{\sin\left[\tan^{-1}\left(\frac{6.00\ \text{cm}}{5.00\ \text{cm}}\right)\right]} = \boxed{1.30}$$

44 •• An optical fiber allows rays of light to propagate long distances by using total internal reflection. Optical fibers are used extensively in medicine and in digital communications. As shown in Figure 31-58 the fiber consists of a core material that has an index of refraction n_2 and radius b surrounded by a cladding material that has an index of refraction $n_3 < n_2$. The *numerical aperture* of the fiber is defined as $\sin\theta_1$, where θ_1 is the angle of incidence of a ray of light that impinges on the center of the end of the fiber and then reflects off the core-cladding interface just at the critical angle. Using the figure as a guide, show that the numerical aperture is given by $\sin\theta_1 = \sqrt{n_2^2 - n_3^2}$ assuming the ray is initially in air. *Hint: Use of the Pythagorean theorem may be required.*

Picture the Problem We can use the geometry of the figure, the law of refraction at the air-n_1 interface, and the condition for total internal reflection at the n_1-n_2 interface to show that the numerical aperture is given by $\sin\theta_1 = \sqrt{n_2^2 - n_3^2}$.

Referring to the figure, note that:

$$\sin\theta_c = \frac{n_3}{n_2} = \frac{a}{c} \text{ and } \sin\theta_2 = \frac{b}{c}$$

Apply the Pythagorean theorem to the right triangle to obtain:

$$a^2 + b^2 = c^2 \text{ or } \frac{a^2}{c^2} + \frac{b^2}{c^2} = 1$$

Solving for $\frac{b}{c}$ yields:

$$\frac{b}{c} = \sqrt{1 - \frac{a^2}{c^2}}$$

Substitute for $\frac{a}{c}$ and $\frac{b}{c}$ to obtain:

$$\sin\theta_2 = \sqrt{1 - \frac{n_3^2}{n_2^2}}$$

Use the law of refraction to relate θ_1 and θ_2:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

Substitute for $\sin\theta_2$, let $n_1 = 1$ (air), and simplify to obtain:

$$\sin\theta_1 = n_2\sqrt{1 - \frac{n_3^2}{n_2^2}} = \boxed{\sqrt{n_2^2 - n_3^2}}$$

45 •• **[SSM]** Find the maximum angle of incidence θ_1 of a ray that would propagate through an optical fiber that has a core index of refraction of 1.492, a core radius of 50.00 μm, and a cladding index of 1.489. See Problem 44.

Picture the Problem We can use the result of Problem 44 to find the maximum angle of incidence under the given conditions.

From Problem 44:

$$\sin\theta_1 = \sqrt{n_2^2 - n_3^2}$$

Solve for θ_1 to obtain:

$$\theta_1 = \sin^{-1}\left(\sqrt{n_2^2 - n_3^2}\right)$$

Substitute numerical values and evaluate θ_1:

$$\theta_1 = \sin^{-1}\left(\sqrt{(1.492)^2 - (1.489)^2}\right) = \boxed{5°}$$

46 •• Calculate the difference in time needed for two pulses of light to travel down 15.0 km of the fiber that is described in Problem 44. Assume that one pulse enters the fiber at normal incidence, and the second pulse enters the fiber at the maximum angle of incidence calculated in Problem 45. In fiber optics, this effect is known as *modal dispersion*.

Picture the Problem We can derive an expression for the difference in the travel times by expressing the travel time for a pulse that enters the fiber at the maximum angle of incidence and a pulse that enters the fiber at normal incidence. Examination of Figure 31-58 reveals that, if the length of the tube is *L*, the distance traveled by the pulse that enters at an angle θ_1 is the ratio of *c* to *a* multiplied by *L*.

The difference in the travel times Δt is given by:

$$\Delta t = t_{\theta_1} - t_{\substack{\text{normal}\\\text{incidence}}} \qquad (1)$$

The travel time for the pulse that enters the fiber at the maximum angle of incidence is:

$$t_{\theta_1} = \frac{\text{distance traveled}}{\text{speed in the medium}} = \frac{L\dfrac{c}{a}}{\dfrac{c}{n_2}}$$

The travel time for the pulse that enters the fiber normally is:

$$t_{\substack{\text{normal}\\\text{incidence}}} = \frac{L}{\dfrac{c}{n_2}}$$

Substitute for t_{θ_1} and $t_{\substack{\text{normal}\\\text{incidence}}}$ in equation (1) to obtain:

$$\Delta t = \frac{L\dfrac{c}{a}}{\dfrac{c}{n_2}} - \frac{L}{\dfrac{c}{n_2}}$$

Simplify to obtain:

$$\Delta t = \frac{n_2 L}{c}\left(\frac{c}{a} - 1\right) \qquad (2)$$

Referring to the figure, note that:

$$\sin\theta_c = \frac{a}{c}$$

From Snell's law, the sine of the critical angle is also given by:

$$\sin\theta_c = \frac{n_3}{n_2} \Rightarrow \frac{a}{c} = \frac{n_3}{n_2}$$

Substitute for c/a in equation (2) to obtain:

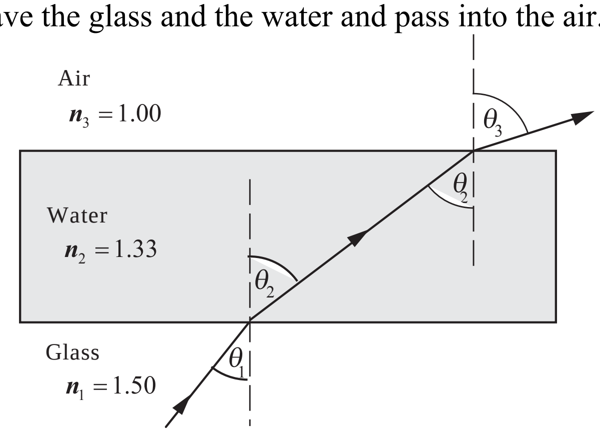
$$\Delta t = \frac{n_2 L}{c}\left(\frac{n_2}{n_3} - 1\right)$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{(1.492)(15\,\text{km})}{2.998\times10^8\ \text{m/s}}\left(\frac{1.492}{1.489} - 1\right) = \boxed{150\,\text{ns}}$$

47 ••• Investigate how a thin film of water on a glass surface affects the critical angle for total reflection. Use n = 1.50 for glass and n = 1.33 for water. (*a*) What is the critical angle for total internal reflection at the glass–water interface? (*b*) Does a range of incident angles exist such that the angles are greater than θ_c for glass-to-air refraction and for which the light rays will leave the glass, travel through the water and then pass into the air?

Picture the Problem Let the index of refraction of glass be represented by n_1, the index of refraction of water by n_2, and the index of refraction of air by n_3. We can apply Snell's law to the glass-water interface under total internal reflection conditions to find the critical angle for total internal reflection. The application of Snell's law to glass-air and glass-water interfaces will allow us to decide whether there are angles of incidence greater than θ_c for glass-to-air refraction for which light rays will leave the glass and the water and pass into the air.



(*a*) Apply Snell's law to the glass-water interface:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

At the critical angle, $\theta_1 = \theta_c$ and $\theta_2 = 90°$:

$$n_1 \sin\theta_c = n_2 \sin 90°$$

Solving for θ_c yields:

$$\theta_c = \sin^{-1}\left[\frac{n_2}{n_1}\sin 90°\right]$$

Substitute numerical values and evaluate θ_c:

$$\theta_c = \sin^{-1}\left[\frac{1.33}{1.50}\sin 90°\right] = \boxed{62.5°}$$

(*b*) Apply Snell's law to a water-air interface at the critical angle for a water-air interface:

$$n_2 \sin\theta_c = n_3 \sin 90°$$

Solving for θ_c yields:

$$\theta_c = \sin^{-1}\left(\frac{n_3}{n_2}\right)$$

Substitute numerical values and evaluate θ_c:

$$\theta_c = \sin^{-1}\left(\frac{1.00}{1.33}\right) = 48.8°$$

Apply Snell's law to a ray incident at the glass-water interface:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

and

$$\theta_1 = \sin^{-1}\left(\frac{n_2}{n_1}\sin\theta_2\right)$$

For $\theta_2 = \theta_c$:

$$\theta_1 = \sin^{-1}\left[\left(\frac{n_2}{n_1}\right)\left(\frac{n_3}{n_2}\right)\right]\sin^{-1}\left(\frac{n_3}{n_1}\right)$$

Substitute numerical values and evaluate θ_1:

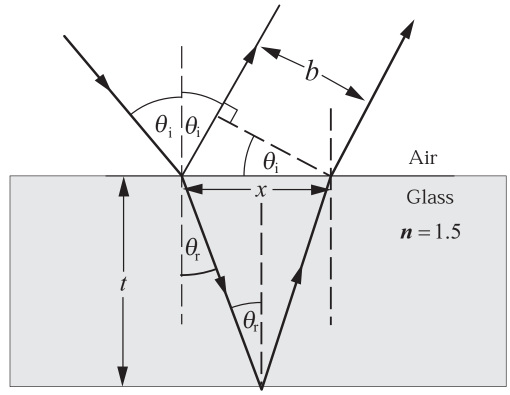
$$\theta_1 = \sin^{-1}\left(\frac{1.00}{1.50}\right) = 41.8°$$

Yes, if $\theta \geq 41.8°$, where θ is the angle of incidence for the rays in glass that are incident on the glass-water boundary, the rays will leave the glass through the water and pass into the air.

48 ••• A laser beam is incident on a plate of glass that is 3.0-cm thick (Figure 31-57). The glass has an index of refraction of 1.5 and the angle of incidence is 40°. The top and bottom surfaces of the glass are parallel. What is the distance *b*

between the beam formed by reflection off the top surface of the glass and the beam reflected off the bottom surface of the glass.

Picture the Problem The situation is shown in the adjacent figure. We can use the geometry of the diagram and trigonometric relationships to derive an expression for *d* in terms of the angles of incidence and refraction. Applying Snell's law will yield θ_r.



Express the distance *x* in terms of *t* and θ_r:

$$x = 2t\tan\theta_r$$

The separation of the reflected rays is:

$$b = x\cos\theta_i$$

Substitute for *x* to obtain:

$$b = 2t\tan\theta_r\cos\theta_i \qquad (1)$$

Apply Snell's law at the air-glass interface to obtain:

$$\sin\theta_i = n\sin\theta_r \Rightarrow \theta_r = \sin^{-1}\left(\frac{\sin\theta_i}{n}\right)$$

Substitute for θ_r in equation (1) to obtain:

$$b = 2t\tan\left[\sin^{-1}\left(\frac{\sin\theta_i}{n}\right)\right]\cos\theta_i$$

Substitute numerical values and evaluate *b*:

$$b = 2(3.0\,\text{cm})\tan\left[\sin^{-1}\left(\frac{\sin 40^\circ}{1.5}\right)\right]\cos 40^\circ$$

$$= \boxed{2.2\,\text{cm}}$$

Dispersion

49 • A beam of light strikes the plane surface of silicate flint glass at an angle of incidence of 45º. The index of refraction of the glass varies with wavelength (see Figure 31-59). How much smaller is the angle of refraction for violet light of wavelength 400 nm than the angle of refraction for red light of wavelength 700 nm?

Picture the Problem We can apply Snell's law of refraction to express the angles of refraction for red and violet light in silicate flint glass.

Express the difference between the angle of refraction for violet light and for red light:

$$\Delta\theta = \theta_{\mathrm{r,red}} - \theta_{\mathrm{r,violet}} \qquad (1)$$

Apply Snell's law of refraction to the interface to obtain:

$$\sin 45° = n \sin\theta_{\mathrm{r}} \Rightarrow \theta_{\mathrm{r}} = \sin^{-1}\left(\frac{1}{\sqrt{2}n}\right)$$

Substituting for θ_{r} in equation (1) yields:

$$\Delta\theta = \sin^{-1}\left(\frac{1}{\sqrt{2}n_{\mathrm{red}}}\right) - \sin^{-1}\left(\frac{1}{\sqrt{2}n_{\mathrm{violet}}}\right)$$

Substitute numerical values and evaluate $\Delta\theta$:

$$\Delta\theta = \sin^{-1}\left(\frac{1}{\sqrt{2}(1.60)}\right) - \sin^{-1}\left(\frac{1}{\sqrt{2}(1.66)}\right) = 26.2° - 25.2° = \boxed{1.0°}$$

50 •• In many transparent materials, dispersion causes different colors (wavelengths) of light to travel at different speeds. This can cause problems in fiber-optic communications systems where pulses of light must travel very long distances in glass. Assuming a fiber is made of silicate crown glass (see Figure 31-59), calculate the difference in travel times that two short pulses of light take to travel 15.0 km in this fiber if the first pulse has a wavelength of 700 nm and the second pulse has a wavelength of 500 nm.

Picture the Problem The transit times will be different because the speed with which light of various wavelengths propagates in silicate crown glass is dependent on the index of refraction. We can use Figure 31-19 to estimate the indices of refraction for pulses of wavelengths 500 and 700 nm.

Express the difference in time needed for two short pulses of light to travel a distance L in the fiber:

$$\Delta t = \frac{L}{v_{500}} - \frac{L}{v_{700}}$$

Substitute for L, v_{500}, and v_{700} and simplify to obtain:

$$\Delta t = \frac{n_{500}L}{c} - \frac{n_{700}L}{c} = \frac{L}{c}\left(n_{500} - n_{700}\right)$$

Use Figure 31-59 to find the indices of refraction of silicate crown glass for the two wavelengths:

$n_{500} \approx 1.51$

and

$n_{700} \approx 1.50$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{15.0\,\text{km}}{2.998\times10^{8}\ \text{m/s}}(1.51-1.50)$$
$$\approx \boxed{0.5\,\mu\text{s}}$$

Polarization

51 • **[SSM]** What is the polarizing angle for light in air that is incident on (*a*) water (n = 1.33), and (*b*) glass (n = 1.50)?

Picture the Problem The polarizing angle is given by Brewster's law: $\tan\theta_\text{p} = n_2/n_1$ where n_1 and n_2 are the indices of refraction on the near and far sides of the interface, respectively.

Use Brewster's law to obtain:

$$\theta_\text{p} = \tan^{-1}\left(\frac{n_2}{n_1}\right)$$

(*a*) For n_1 = 1 and n_2 = 1.33:

$$\theta_\text{p} = \tan^{-1}\left(\frac{1.33}{1.00}\right) = \boxed{53.1°}$$

(*b*) For n_1 = 1 and n_2 = 1.50:

$$\theta_\text{p} = \tan^{-1}\left(\frac{1.50}{1.00}\right) = \boxed{56.3°}$$

52 • Light that is horizontally polarized is incident on a polarizing sheet. It is observed that only 15 percent of the intensity of the incident light is transmitted through the sheet. What angle does the transmission axis of the sheet make with the horizontal?

Picture the Problem The intensity of the transmitted light I is related to the intensity of the incident light I_0 and the angle the transmission axis makes with the horizontal θ according to $I = I_0\cos^2\theta$.

Express the intensity of the transmitted light in terms of the intensity of the incident light and the angle the transmission axis makes with the horizontal:

$$I = I_0\cos^2\theta \Rightarrow \theta = \cos^{-1}\left(\sqrt{\frac{I}{I_0}}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left(\sqrt{0.15}\right) = \boxed{67°}$$

53 • Two polarizing sheets have their transmission axes crossed so that no light gets through. A third sheet is inserted between the first two so that its transmission axis makes an angle θ with the transmission axis of the first sheet. Unpolarized light of intensity I_0 is incident on the first sheet. Find the intensity of the light transmitted through all three sheets if (*a*) $\theta = 45^\circ$ and (*b*) $\theta = 30^\circ$.

Picture the Problem Let I_n be the intensity after the *n*th polarizing sheet and use $I = I_0\cos^2\theta$ to find the intensity of the light transmitted through all three sheets for $\theta = 45^\circ$ and $\theta = 30^\circ$.

(*a*) The intensity of the light between the first and second sheets is:

$$I_1 = \tfrac{1}{2}I_0$$

The intensity of the light between the second and third sheets is:

$$I_2 = I_1\cos^2\theta_{1,2} = \tfrac{1}{2}I_0\cos^2 45^\circ = \tfrac{1}{4}I_0$$

The intensity of the light that has passed through the third sheet is:

$$I_3 = I_2\cos^2\theta_{2,3} = \tfrac{1}{4}I_0\cos^2 45^\circ = \boxed{\tfrac{1}{8}I_0}$$

(*b*) The intensity of the light between the first and second sheets is:

$$I_1 = \tfrac{1}{2}I_0$$

The intensity of the light between the second and third sheets is:

$$I_2 = I_1\cos^2\theta_{1,2} = \tfrac{1}{2}I_0\cos^2 30^\circ = \tfrac{3}{8}I_0$$

The intensity of the light that has passed through the third sheet is:

$$I_3 = I_2\cos^2\theta_{2,3} = \tfrac{3}{8}I_0\cos^2 60^\circ = \boxed{\tfrac{3}{32}I_0}$$

54 • A horizontal 5.0 mW laser beam that is vertically polarized is incident on a sheet that is oriented with its transmission axis vertical. Behind the first sheet is a second sheet that is oriented so that its transmission axis makes an angle of 27° with respect to the vertical. What is the power of the beam transmitted through the second sheet?

Picture the Problem Because the light is polarized in the vertical direction and the first polarizer is also vertically polarized, no loss of intensity results from the first transmission. We can use Malus's law to find the intensity of the light after it has passed through the second polarizer.

The intensity of the beam is the ratio of its power to cross-sectional area:

$$I = \frac{P}{A}$$

Express the intensity of the light between the first and second polarizers:

$$I_1 = I_0 \text{ and } P_1 = P_0$$

Express the law of Malus in terms of the power of the beam:

$$\frac{P}{A} = \frac{P_0}{A}\cos^2\theta \Rightarrow P = P_0\cos^2\theta$$

Express the power of the beam after the second transmission:

$$P_2 = P_1\cos^2\theta_{1,2} = P_0\cos^2\theta_{12}$$

Substitute numerical values and evaluate P_2:

$$P_2 = (5.0\,\text{mW})\cos^2 27° = \boxed{4.0\,\text{mW}}$$

55 •• **[SSM]** The polarizing angle for light in air that is incident on a certain substance is 60º. (*a*) What is the angle of refraction of light incident at this angle? (*b*) What is the index of refraction of this substance?

Picture the Problem Assume that light is incident in air (n_1 = 1.00). We can use the relationship between the polarizing angle and the angle of refraction to determine the latter and Brewster's law to find the index of refraction of the substance.

(*a*) At the polarizing angle, the sum of the angles of polarization and refraction is 90°:

$$\theta_p + \theta_r = 90° \Rightarrow \theta_r = 90° - \theta_p$$

Substitute for θ_p to obtain:

$$\theta_r = 90° - 60° = \boxed{30°}$$

(*b*) From Brewster's law we have:

$$\tan\theta_p = \frac{n_2}{n_1}$$

or, because n_1 = 1.00,

$$n_2 = \tan\theta_p$$

Substitute for θ_p and evaluate n_2:

$$n_2 = \tan 60° = \boxed{1.7}$$

56 •• Two polarizing sheets have their transmission axes crossed so that no light is transmitted. A third sheet is inserted so that its transmission axis makes an angle θ with the transmission axis of the first sheet. (*a*) Derive an expression for the intensity of the transmitted light as a function of θ. (*b*) Show that the intensity transmitted through all three sheets is maximum when θ = 45º.

Picture the Problem Let I_n be the intensity after the *n*th polarizing sheet and use $I = I_0 \cos^2\theta$ to find the intensity of the light transmitted through the three sheets.

(*a*) The intensity of the light between the first and second sheets is:

$$I_1 = \tfrac{1}{2} I_0$$

The intensity of the light between the second and third sheets is:

$$I_2 = I_1 \cos^2\theta_{1,2} = \tfrac{1}{2} I_0 \cos^2\theta$$

Express the intensity of the light that has passed through the third sheet and simplify to obtain:

$$\begin{aligned} I_3 &= I_2 \cos^2\theta_{2,3} \\ &= \tfrac{1}{2} I_0 \cos^2\theta \cos^2(90° - \theta) \\ &= \tfrac{1}{2} I_0 \cos^2\theta \sin^2\theta \\ &= \tfrac{1}{8} I_0 (2\cos\theta\sin\theta)^2 \\ &= \boxed{\tfrac{1}{8} I_0 \sin^2 2\theta} \end{aligned}$$

(*b*) Because the sine function is a maximum when its argument is 90°, the maximum value of I_3 occurs when $\theta = 45°$.

57 •• If the middle polarizing sheet in Problem 56 is rotating at an angular speed ω about an axis parallel with the light beam, find an expression for the intensity transmitted through all three sheets as a function of time. Assume that $\theta = 0$ at time $t = 0$.

Picture the Problem Let I_n be the intensity after the *n*th polarizing sheet, use $I = I_0 \cos^2\theta$ to find the intensity of the light transmitted through each sheet, and replace θ with ωt.

The intensity of the light between the first and second sheets is:

$$I_1 = \tfrac{1}{2} I_0$$

The intensity of the light between the second and third sheets is:

$$I_2 = I_1 \cos^2\theta_{1,2} = \tfrac{1}{2} I_0 \cos^2\omega t$$

Express the intensity of the light that has passed through the third sheet and simplify to obtain:

$$\begin{aligned} I_3 &= I_2 \cos^2\theta_{2,3} \\ &= \tfrac{1}{2} I_0 \cos^2\omega t \cos^2(90° - \omega t) \\ &= \tfrac{1}{2} I_0 \cos^2\omega t \sin^2\omega t \\ &= \tfrac{1}{8} I_0 (2\cos\omega t\sin\omega t)^2 \\ &= \boxed{\tfrac{1}{8} I_0 \sin^2 2\omega t} \end{aligned}$$

58 •• A stack of $N + 1$ ideal polarizing sheets is arranged so that each sheet is rotated by an angle of $\pi/(2N)$ rad with respect to the preceding sheet. A linearly polarized light wave of intensity I_0 is incident normally on the stack. The incident light is polarized along the transmission axis of the first sheet and is therefore perpendicular to the transmission axis of the last sheet in the stack.
(*a*) Show that the intensity of the light transmitted through the entire stack is given by $I_0 \cos^{2N}\left[\pi/(2N)\right]$. (*b*) Using a **spreadsheet** or graphing program, plot the transmitted intensity as a function of N for values of N from 2 to 100. (*c*) What is the direction of polarization of the transmitted beam in each case?

Picture the Problem Let I_n be the intensity after the nth polarizing sheet and use $I = I_0 \cos^2\theta$ to find the ratio of I_{n+1} to I_n.

(*a*) Find the ratio of I_{n+1} to I_n:

$$\frac{I_{n+1}}{I_n} = \cos^2\frac{\pi}{2N}$$

Because there are N such reductions of intensity:

$$\frac{I_{N+1}}{I_1} = \frac{I_{N+1}}{I_0} = \cos^{2N}\left(\frac{\pi}{2N}\right)$$

and

$$I_{N+1} = \boxed{I_0 \cos^{2N}\left(\frac{\pi}{2N}\right)}$$

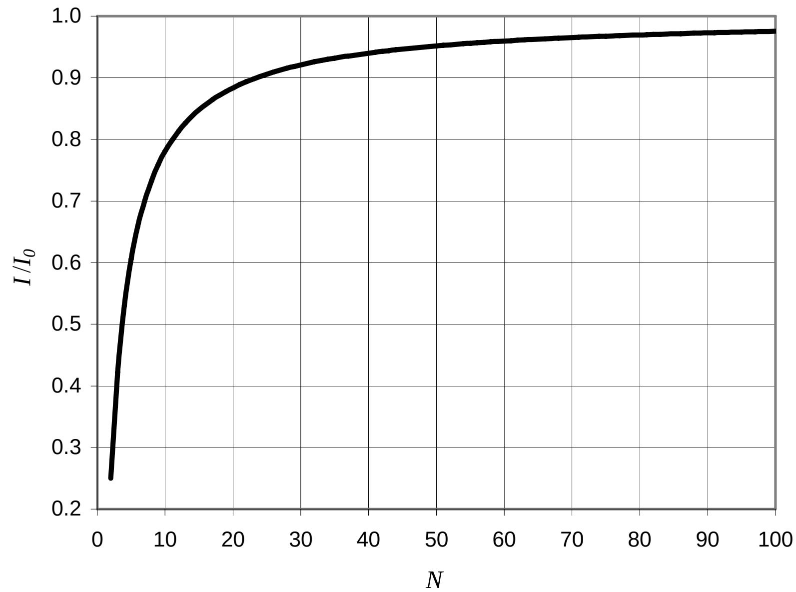
(*b*) A spreadsheet program to graph I_{N+1}/I_0 as a function of N is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A2	2	N
A3	A2 + 1	$N + 1$
B2	(cos(PI()/(2*A2))^(2*A2)	$\cos^{2N}\left(\frac{\pi}{2N}\right)$

	A	B
1	N	I/I_0
2	2	0.250
3	3	0.422
4	4	0.531
5	5	0.605
95	95	0.974
96	96	0.975
97	97	0.975
98	98	0.975
99	99	0.975

100	100	0.976

A graph of I/I_0 as a function of N follows.



(c) The transmitted light, if any, is polarized parallel to the transmission axis of the last sheet. (For $N = 2$ there is no transmitted light.)

Remarks: The correct values for the intensity of the transmitted light would be significantly smaller than predicted above because of reflection losses.

59 •• [SSM] The device described in Problem 58 could serve as a *polarization rotator*, which changes the linear plane of polarization from one direction to another. The efficiency of such a device is measured by taking the ratio of the output intensity at the desired polarization to the input intensity. The result of Problem 58 suggests that the highest efficiency is achieved by using a large value for the number N. A small amount of intensity is lost regardless of the input polarization when using a real polarizer. For each polarizer, assume the transmitted intensity is 98 percent of the amount predicted by the law of Malus and use a **spreadsheet** or graphing program to determine the optimum number of sheets you should use to rotate the polarization 90º.

Picture the Problem Let I_n be the intensity after the nth polarizing sheet and use $I = I_0\cos^2\theta$ to find the ratio of I_{n+1} to I_n. Because each sheet introduces a 2% loss of intensity, the net transmission after N sheets $(0.98)^N$.

Find the ratio of I_{n+1} to I_n:

$$\frac{I_{n+1}}{I_n} = (0.98)\cos^2\frac{\pi}{2N}$$

Because there are N such reductions of intensity:

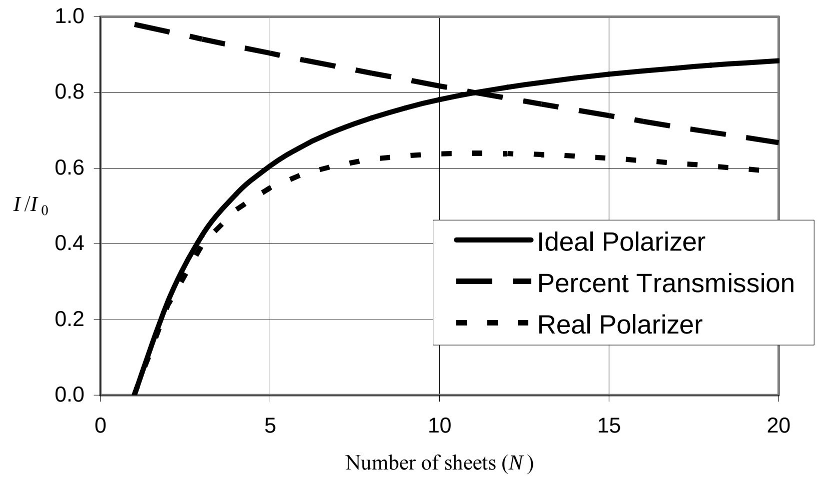
$$\frac{I_{N+1}}{I_0}=(0.98)^N\cos^{2N}\left(\frac{\pi}{2N}\right)$$

A spreadsheet program to graph I_{N+1}/I_0 for an ideal polarizer as a function of N, the percent transmission, and I_{N+1}/I_0 for a real polarizer as a function of N is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A3	1	N
B2	(cos(PI()/(2*A2))^(2*A2)	$\cos^{2N}\left(\frac{\pi}{2N}\right)$
C3	(0.98)^A3	$(0.98)^N$
D4	B3*C3	$(0.98)^N\cos^{2N}\left(\frac{\pi}{2N}\right)$

	A	B	C	D
1		Ideal	Percent	Real
2	N	Polarizer	Transmission	Polarizer
3	1	0.000	0.980	0.000
4	2	0.250	0.960	0.240
5	3	0.422	0.941	0.397
6	4	0.531	0.922	0.490
7	5	0.605	0.904	0.547
8	6	0.660	0.886	0.584
9	7	0.701	0.868	0.608
10	8	0.733	0.851	0.624
11	9	0.759	0.834	0.633
12	10	0.781	0.817	0.638
13	11	0.798	0.801	0.639
14	12	0.814	0.785	0.638
15	13	0.827	0.769	0.636
16	14	0.838	0.754	0.632
17	15	0.848	0.739	0.626
18	16	0.857	0.724	0.620
19	17	0.865	0.709	0.613
20	18	0.872	0.695	0.606
21	19	0.878	0.681	0.598
22	20	0.884	0.668	0.590

A graph of I/I_0 as a function of N for the quantities described above follows:



Inspection of the table, as well as of the graph, tells us that the optimum number of sheets is $\boxed{11.}$

Remarks: The correct values for the intensity of the transmitted light would be significantly smaller than predicted above because of reflection losses.

60 •• Show mathematically that a linearly polarized wave can be thought of as a superposition of a right and a left circularly polarized wave.

Picture the Problem A circularly polarized wave is said to be *right circularly polarized* if the electric and magnetic fields rotate clockwise when viewed along the direction of propagation and *left circularly polarized* if the fields rotate counterclockwise.

For a circularly polarized wave, the x and y components of the electric field are given by:

$$E_x = E_0 \cos\omega t$$

and

$$E_y = E_0 \sin\omega t \text{ or } E_y = -E_0 \sin\omega t$$

for left and right circular polarization, respectively.

For a wave polarized along the x axis:

$$\vec{E}_{\text{right}} + \vec{E}_{\text{left}} = E_0 \cos\omega t\,\hat{i} + E_0 \cos\omega t\,\hat{i}$$

$$= \boxed{2E_0 \cos\omega t\,\hat{i}}$$

61 •• Suppose that the middle sheet in Problem 53 is replaced by two polarizing sheets. If the angle between the transmission axes in the second, third, and fourth sheets in the stack make angles of 30º, 60º and 90º, respectively, with the transmission axis of the first sheet, (a) what is the intensity of the transmitted

light? (*b*) How does this intensity compare with the intensity obtained in Part (*a*) of Problem 53?

Picture the Problem Let I_n be the intensity after the *n*th polarizing sheet and use $I = I_0\cos^2\theta$ to find the intensity of the light transmitted by the four sheets.

(*a*) The intensity of the light between the first and second sheets is:

$$I_1 = \tfrac{1}{2}I_0$$

The intensity of the light between the second and third sheets is:

$$I_2 = I_1\cos^2\theta_{1,2} = \tfrac{1}{2}I_0\cos^2 30° = \tfrac{3}{8}I_0$$

The intensity of the light between the third and fourth sheets is:

$$I_3 = I_2\cos^2\theta_{2,3} = \tfrac{3}{8}I_0\cos^2 30° = \tfrac{9}{32}I_0$$

The intensity of the light to the right of the fourth sheet is:

$$I_4 = I_3\cos^2\theta_{3,4} = \tfrac{9}{32}I_0\cos^2 30° = \tfrac{27}{128}I_0$$
$$= \boxed{0.211I_0}$$

(*b*) The intensity with four sheets at angles of 0°, 30°, 30° and 90° is greater the intensity of three sheets at angles of 0°, 45° and 90° by a factor of 1.69.

Remarks: We could also apply the result obtained in Problem 58(*a*) to solve this problem.

62 •• Show that the electric field of a circularly polarized wave propagating parallel with the *x* axis can be expressed by

$$\vec{E} = E_0\sin(kx+\omega t)\hat{j} + E_0\cos(kx+\omega t)\hat{k}.$$

Picture the Problem A circularly polarized wave may be resolved into two linearly polarized waves, of equal amplitude, 90 degrees apart and with their planes of polarization at right angles to each other. The components of the electric field $\vec{E}$ of a circularly polarized wave propagating parallel to the *x* axis are given by $E_x = E_0\sin\omega t$ and $E_y = E_0\cos\omega t$.

The electric field $\vec{E}$ is the vector sum of its components:

$$\vec{E} = E_x\hat{j} + E_y\hat{k}$$

For an electric field propagating parallel with the *x* axis and in the −*x* direction:

$$E_x = E_0\sin(kx+\omega t)$$
and
$$E_y = E_0\cos(kx+\omega t)$$

Substituting for E_x and E_y yields:

$$\vec{E} = \boxed{E_0 \sin(kx + \omega t)\hat{j} + E_0 \cos(kx + \omega t)\hat{k}}$$

63 •• [SSM] A circularly polarized wave is said to be *right circularly polarized* if the electric and magnetic fields rotate clockwise when viewed along the direction of propagation and *left circularly polarized* if the fields rotate counterclockwise. (*a*) What is the sense of the circular polarization for the wave described by the expression in Problem 62? (*b*) What would be the expression for the electric field of a circularly polarized wave traveling in the same direction as the wave in Problem 60, but with the fields rotating in the opposite direction?

Picture the Problem We can apply the given definitions of right and left circular polarization to the electric field and magnetic fields of the wave.

(*a*) The electric field of the wave in Problem 62 is:

$$\vec{E} = E_0 \sin(kx + \omega t)\hat{j} + E_0 \cos(kx + \omega t)\hat{k}$$

The corresponding magnetic field is:

$$\vec{B} = B_0 \sin(kx + \omega t)\hat{k} - B_0 \cos(kx + \omega t)\hat{j}$$

Because these fields rotate clockwise when viewed along the direction of propagation, the wave is right circularly polarized.

(*b*) For a left circularly polarized wave traveling in the opposite direction:

$$\vec{E} = \boxed{E_0 \sin(kx + \omega t)\hat{j} - E_0 \cos(kx + \omega t)\hat{k}}$$

Sources of Light

64 • A helium–neon laser emits light that has a wavelength equal to 632.8 nm and has a power output of 4.00 mW. How many photons are emitted per second by this laser?

Picture the Problem We can express the number of photons emitted per second as the ratio of the power output of the laser and energy of a single photon.

Relate the number of photons per second n to the power output of the pulse and the energy of a single photon E_{photon}:

$$n = \frac{P}{E_{\text{photon}}}$$

The energy of a photon is given by:

$$E_{\text{photon}} = \frac{hc}{\lambda}$$

Substitute for E_{photon} to obtain:

$$n = \frac{\lambda P}{hc}$$

Substitute numerical values and evaluate n:

$$n = \frac{(632.8\,\text{nm})(4.00\,\text{mW})}{1240\,\text{eV}\cdot\text{nm}}\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}} = \boxed{1.27\times10^{16}\ \text{photons/s}}$$

65 • The first excited state of an atom of a gas is 2.85 eV above the ground state. (*a*) What is the maximum wavelength of radiation for resonance absorption by atoms of the gas that are in the ground state? (*b*) If the gas is irradiated with monochromatic light that has a wavelength of 320 nm, what is the wavelength of the Raman scattered light?

Picture the Problem We can use the Einstein equation for photon energy to find the wavelength of the radiation for resonance absorption. We can use the same relationship, with $E_{\text{Raman}} = E_{\text{inc}} - \Delta E$ where ΔE is the energy for resonance absorption, to find the wavelength of the Raman scattered light.

(*a*) Use the Einstein equation for photon energy to relate the wavelength of the radiation to energy of the first excited state:

$$\lambda = \frac{hc}{E}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{2.85\,\text{eV}} = \boxed{435\,\text{nm}}$$

(*b*) The wavelength of the Raman scattered light is given by:

$$\lambda_{\text{Raman}} = \frac{1240\,\text{eV}\cdot\text{nm}}{E_{\text{Raman}}}$$

Relate the energy of the Raman scattered light E_{Raman} to the energy of the incident light E_{inc}:

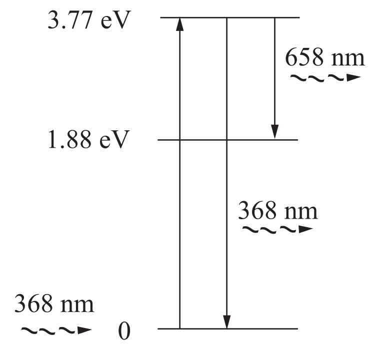
$$\begin{aligned} E_{\text{Raman}} &= E_{\text{inc}} - \Delta E \\ &= \frac{1240\,\text{eV}\cdot\text{nm}}{320\,\text{nm}} - 2.85\,\text{eV} \\ &= 1.025\,\text{eV} \end{aligned}$$

Substitute numerical values and evaluate λ_{Raman}:

$$\lambda_{\text{Raman}} = \frac{1240\,\text{eV}\cdot\text{nm}}{1.025\,\text{eV}} = \boxed{1210\,\text{nm}}$$

66 •• A gas is irradiated with monochromatic ultraviolet light that has a wavelength of 368 nm. Scattered light that has a wavelength equal to 368 nm is observed, and scattered light that has a wavelength of 658-nm is also observed. Assuming that the gas atoms were in their ground state prior to irradiation, find the energy difference between the ground state and the excited state obtained by the irradiation.

Picture the Problem The incident radiation will excite atoms of the gas to higher energy states. The scattered light that is observed is a consequence of these atoms returning to their ground state. The energy difference between the ground state and the atomic state excited by the irradiation is given by $\Delta E = hf = \dfrac{hc}{\lambda}$.



The energy difference between the ground state and the atomic state excited by the irradiation is given by:

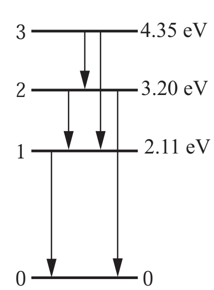
$$\Delta E = hf = \frac{hc}{\lambda} = \frac{1240\,\text{eV}\cdot\text{nm}}{\lambda}$$

Substitute 368 nm for λ and evaluate ΔE:

$$\Delta E = \frac{1240\,\text{eV}\cdot\text{nm}}{368\,\text{nm}} = \boxed{3.37\,\text{eV}}$$

67 •• **[SSM]** Sodium has excited states 2.11 eV, 3.20 eV, and 4.35 eV above the ground state. Assume that the atoms of the gas are all in the ground state prior to irradiation. (*a*) What is the maximum wavelength of radiation that will result in resonance fluorescence? What is the wavelength of the fluorescent radiation? (*b*) What wavelength will result in excitation of the state 4.35 eV above the ground state? If that state is excited, what are the possible wavelengths of resonance fluorescence that might be observed?

Picture the Problem The ground state and the three excited energy levels are shown in the diagram to the right. Because the wavelength is related to the energy of a photon by $\lambda = hc/\Delta E$, longer wavelengths correspond to smaller energy differences.



(*a*) The maximum wavelength of radiation that will result in resonance fluorescence corresponds to an excitation to the 3.20 eV level followed by decays to the 2.11 eV level and the ground state:

$$\lambda_{\max} = \frac{1240\,\text{eV}\cdot\text{nm}}{3.20\,\text{eV}} = \boxed{388\,\text{nm}}$$

The fluorescence wavelengths are:

$$\lambda_{2\to1} = \frac{1240\,\text{eV}\cdot\text{nm}}{3.20\,\text{eV} - 2.11\,\text{eV}} = \boxed{1140\,\text{nm}}$$

and

$$\lambda_{1\to0} = \frac{1240\,\text{eV}\cdot\text{nm}}{2.11\,\text{eV} - 0} = \boxed{588\,\text{nm}}$$

(*b*) For excitation:

$$\lambda_{0\to3} = \frac{1240\,\text{eV}\cdot\text{nm}}{4.35\,\text{eV}} = 285\,\text{nm}$$

(**not in visible the spectrum**)

The fluorescence wavelengths corresponding to the possible transitions are:

$$\lambda_{3\to2} = \frac{1240\,\text{eV}\cdot\text{nm}}{4.35\,\text{eV} - 3.20\,\text{eV}} = 1080\,\text{nm}$$

(**not in visible spectrum**)

$$\lambda_{2\to1} = \frac{1240\,\text{eV}\cdot\text{nm}}{3.20\,\text{eV} - 2.11\,\text{eV}} = 1140\,\text{nm}$$

(**not in visible spectrum**)

$$\lambda_{1\to0} = \frac{1240\,\text{eV}\cdot\text{nm}}{2.11\,\text{eV} - 0} = \boxed{588\,\text{nm}}$$

$$\lambda_{3\to1} = \frac{1240\,\text{eV}\cdot\text{nm}}{4.35\,\text{eV} - 2.11\,\text{eV}} = \boxed{554\,\text{nm}}$$

and

$$\lambda_{2\to0} = \frac{1240\,\text{eV}\cdot\text{nm}}{3.20\,\text{eV} - 0} = 388\,\text{nm}$$

(**not in visible spectrum**)

68 •• Singly ionized helium is a hydrogen-like atom that has a nuclear charge of +2*e*. Its energy levels are given by $E_n = -4E_0/n^2$, where $n = 1, 2, \ldots$ and $E_0 = 13.6$ eV. If a beam of visible white light is sent through a gas of singly ionized helium, at what wavelengths will dark lines be found in the spectrum of the transmitted radiation? (Assume that the ions of the gas are all in the same state with energy E_1 prior to irradiation.)

Determine the Concept The energy difference between the ground state and the first excited state is $3E_0$ = 40.8 eV, corresponding to a wavelength of 30.4 nm. This is in the far ultraviolet, well outside the visible range of wavelengths. There will be no dark lines in the transmitted radiation.

69 • **[SSM]** A pulse from a ruby laser has an average power of 10 MW and lasts 1.5 ns. (*a*) What is the total energy of the pulse? (*b*) How many photons are emitted in this pulse?

Picture the Problem We can use the definition of power to find the total energy of the pulse. The ratio of the total energy to the energy per photon will yield the number of photons emitted in the pulse.

(*a*) Use the definition of power to obtain:

$$E = P\Delta t$$

Substitute numerical values and evaluate *E*:

$$E = (10\,\text{MW})(1.5\,\text{ns}) = \boxed{15\,\text{mJ}}$$

(*b*) Relate the number of photons *N* to the total energy in the pulse and the energy of a single photon E_{photon}:

$$N = \frac{E}{E_{\text{photon}}}$$

The energy of a photon is given by:

$$E_{\text{photon}} = \frac{hc}{\lambda}$$

Substitute for E_{photon} to obtain:

$$N = \frac{\lambda E}{hc}$$

Substitute numerical values (the wavelength of light emitted by a ruby laser is 694.3 nm) and evaluate *N*:

$$N = \frac{(694.3\,\text{nm})(15\,\text{mJ})}{1240\,\text{eV}\cdot\text{nm}}\,\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}} = \boxed{5.2\times10^{16}}$$

General Problems

70 • A beam of red light that has a wavelength of 700 nm in air travels in water. (*a*) What is the wavelength in water? (*b*) Does a swimmer underwater observe the same color or a different color for this light?

Picture the Problem We can use $v = f\lambda$ and the definition of the index of refraction to relate the wavelength of light in a medium whose index of refraction is n to the wavelength of light in air.

(a) The wavelength λ_n of light in a medium whose index of refraction is n is given by:

$$\lambda_n = \frac{v}{f} = \frac{c}{nf} = \frac{\lambda_0}{n}$$

Substitute numerical values and evaluate λ_{water}:

$$\lambda_{\text{water}} = \frac{700\,\text{nm}}{n_{\text{water}}} = \frac{700\,\text{nm}}{1.33} = \boxed{526\,\text{nm}}$$

(b) Because the color observed depends on the frequency of the light, a swimmer observes the same color in air and in water.

71 •• **[SSM]** The critical angle for total internal reflection for a substance is 48°. What is the polarizing angle for this substance?

Picture the Problem We can use Snell's law, under critical angle and polarization conditions, to relate the polarizing angle of the substance to the critical angle for internal reflection.

Apply Snell's law, under critical angle conditions, to the interface:

$$n_1 \sin\theta_c = n_2 \quad (1)$$

Apply Snell's law, under polarization conditions, to the interface:

$$n_1 \sin\theta_p = n_2 \sin(90° - \theta_p) = n_2 \cos\theta_p$$

or

$$\tan\theta_p = \frac{n_2}{n_1} \Rightarrow \theta_p = \tan^{-1}\left(\frac{n_2}{n_1}\right) \quad (2)$$

Solve equation (1) for the ratio of n_2 to n_1:

$$\frac{n_2}{n_1} = \sin\theta_c$$

Substitute for n_2/n_1 in equation (2) to obtain:

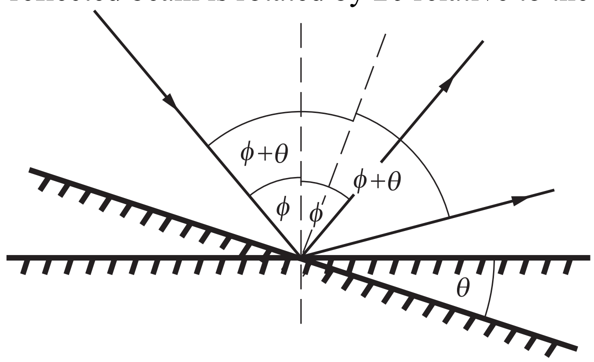
$$\theta_p = \tan^{-1}(\sin\theta_c)$$

Substitute numerical values and evaluate θ_p:

$$\theta_p = \tan^{-1}(\sin 48°) = \boxed{37°}$$

72 •• Show that when a flat mirror is rotated through an angle θ about an axis in the plane of the mirror, a reflected beam of light (from a fixed incident beam) that is perpendicular to the rotation axis is rotated through 2θ.

Picture the Problem Let ϕ be the initial angle of incidence. Since the angle of reflection with the normal to the mirror is also ϕ, the angle between incident and reflected rays is 2ϕ. If the mirror is now rotated by a further angle θ, the angle of incidence is increased by θ to $\phi + \theta$, and so is the angle of reflection. Consequently, the reflected beam is rotated by 2θ relative to the incident beam.



73 •• **[SSM]** Use Figure 31-59 to calculate the critical angles for light initially in silicate flint glass that is incident on a glass–air interface if the light is (*a*) violet light of wavelength 400 nm and (*b*) red light of wavelength 700 nm.

Picture the Problem We can apply Snell's law at the glass-air interface to express θ_c in terms of the index of refraction of the glass and use Figure 31-59 to find the index of refraction of the glass for the given wavelengths of light.

Apply Snell's law at the glass-air interface:

$$n_1 \sin\theta_1 = n_2 \sin\theta_2$$

If $\theta_1 = \theta_c$ and $n_2 = 1$:

$$n_1 \sin\theta_c = \sin 90° = 1$$

and

$$\theta_c = \sin^{-1}\left(\frac{1}{n_1}\right)$$

(*a*) For violet light of wavelength 400 nm, $n_1 = 1.67$:

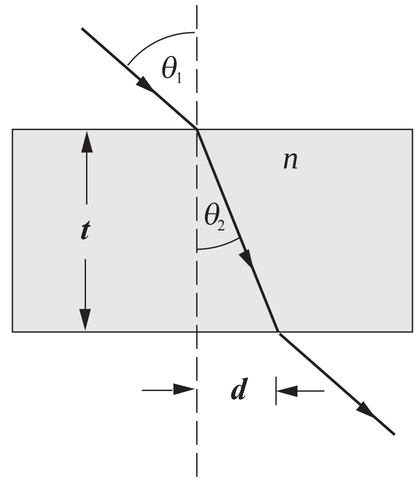
$$\theta_c = \sin^{-1}\left(\frac{1}{1.67}\right) = \boxed{36.8°}$$

(*b*) For red light of wavelength 700 nm, $n_1 = 1.60$:

$$\theta_c = \sin^{-1}\left(\frac{1}{1.60}\right) = \boxed{38.7°}$$

74 •• Light is incident on a slab of transparent material at an angle θ_1, as shown in Figure 31-60. The slab has a thickness t and an index of refraction n. Show that $n = \sin(\theta_1)/\left[\tan^{-1}(d/t)\right]$, where d is the distance shown in the figure.

Picture the Problem We can apply Snell's law at the air-slab interface to express the index of refraction n in terms of θ_1 and θ_2 and then use the geometry of the figure to relate θ_2 to t and d.



Applying Snell's law to the first interface yields:

$$\sin\theta_1 = n\sin\theta_2 \Rightarrow n = \frac{\sin\theta_1}{\sin\theta_2}$$

From the diagram:

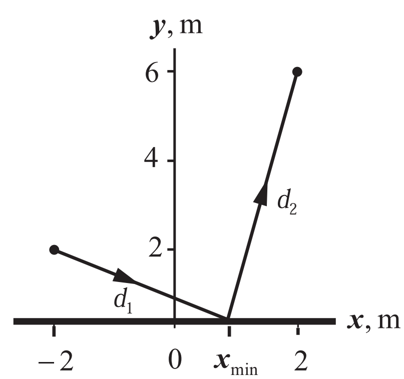
$$d = t\tan\theta_2 \Rightarrow \theta_2 = \tan^{-1}\left(\frac{d}{t}\right)$$

Substitute for θ_2 to obtain:

$$n = \boxed{\frac{\sin\theta_1}{\sin\left[\tan^{-1}\left(\frac{d}{t}\right)\right]}}$$

75 •• A ray of light begins at the point (–2.00 m, 2.00 m, 0.00 m), strikes a mirror in the $y = 0$ plane at some point $(x, 0, 0)$, and reflects through the point (2.00 m, 6.00 m, 0.00 m). (*a*) Find the value of x that makes the total distance traveled by the ray a minimum. (*b*) What is the angle of incidence on the reflecting plane? (*c*) What is the angle of reflection?

Picture the Problem We can write an expression for the total distance traveled by the light as a function of x and set the derivative of this expression equal to zero to find the value of x that minimizes the distance traveled by the light. The adjacent figure shows the two points and the reflecting surface. The x and y coordinates are in meters.



(*a*) Express the total distance D traveled by the light:

$$D = d_1 + d_2 = \sqrt{(x+2)^2 + 4} + \sqrt{(2-x)^2 + 36}$$

Differentiate D with respect to x:

$$\frac{dD}{dx}=\frac{d}{dx}\left[\sqrt{(x+2)^2+4}+\sqrt{(2-x)^2+36}\right]$$
$$=\tfrac{1}{2}\left[(x+2)^2+4\right]^{-\frac{1}{2}}2(x+2)+\tfrac{1}{2}\left[(2-x)^2+36\right]^{-\frac{1}{2}}2(2-x)(-1)$$

Setting this expression equal to zero for extreme values yields:

$$\frac{x_{\text{min}}+2}{\sqrt{(x_{\text{min}}+2)^2+4}}-\frac{2-x_{\text{min}}}{\sqrt{(2-x_{\text{min}})^2+36}}=0$$

Solve for x_{min} to obtain: $\quad x_{\text{min}}=\boxed{-1.00\,\text{m}}$

(*b*) Letting the coordinates of the point at which the ray originates be (x_1, y_1) and the coordinates of the terminal point be (x_2, y_2), the tangent of the angle of incidence is given by:

$$\tan\theta_{\text{i}}=\left|\frac{x-x_1}{y-y_1}\right|\Rightarrow\theta_{\text{i}}=\tan^{-1}\left(\left|\frac{x-x_1}{y-y_1}\right|\right)$$

where $(x, y) = (-1.00\text{ m}, 0)$.

Substitute numerical values and evaluate θ_{i}:

$$\theta_{\text{i}}=\tan^{-1}\left[\left|\frac{-1.00\,\text{m}-(-2.00\,\text{m})}{0-2.00\,\text{m}}\right|\right]=\boxed{26.6^\circ}$$

(*c*) Letting the coordinates of the point at which the ray originates be (x, y) and the coordinates of the terminal point be (x_2, y_2), the tangent of the angle of reflection is given by:

$$\tan\theta_{\text{r}}=\frac{x_2-x}{y_2-y}\Rightarrow\theta_{\text{r}}=\tan^{-1}\left(\frac{x_2-x}{y_2-y}\right)$$

where $(x, y) = (-1.00\text{ m}, 0)$.

Substitute numerical values and evaluate θ_{r}:

$$\theta_{\text{r}}=\tan^{-1}\left[\frac{2.00\,\text{m}-(-1.00\,\text{m})}{6.00\,\text{m}-0}\right]=\boxed{26.6^\circ}$$

76 •• To produce a polarized laser beam a plate of transparent material, (Figure 31-61) is placed in the laser cavity and oriented so the light strikes it at the polarizing angle. Such a plate is called a Brewster window. Show that if θ_{P1} is the

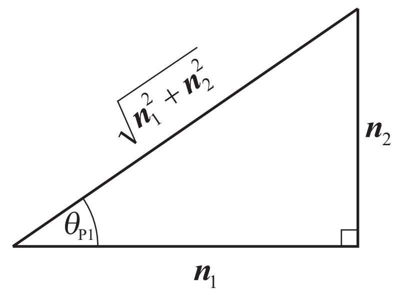
polarizing angle for the n_1 to n_2 interface, then θ_{P2} is the polarizing angle for the n_2 to n_1 interface.

Picture the Problem Let the angle of refraction at the first interface by θ_1 and the angle of refraction at the second interface be θ_2. We can apply Snell's law at each interface and eliminate θ_1 and n_2 to show that $\theta_2 = \theta_{P2}$.

Apply Brewster's law at the n_1-n_2 interface:

$$\tan\theta_{P1} = \frac{n_2}{n_1}$$

Draw a reference triangle consistent with Brewster's law:



Apply Snell's law at the n_1-n_2 interface:

$$n_1 \sin\theta_{P1} = n_2 \sin\theta_1$$

Solve for θ_1 to obtain:

$$\theta_1 = \sin^{-1}\left(\frac{n_1}{n_2}\sin\theta_{P1}\right)$$

Referring to the reference triangle we note that:

$$\theta_1 = \sin^{-1}\left(\frac{n_1}{n_2}\frac{n_2}{\sqrt{n_1^2 + n_2^2}}\right)$$

$$= \sin^{-1}\left(\frac{n_1}{\sqrt{n_1^2 + n_2^2}}\right)$$

that is, θ_1 is the complement of θ_{p1}.

Apply Snell's law at the n_2-n_1 interface:

$$n_2 \sin\theta_1 = n_1 \sin\theta_2$$

Solve for θ_2 to obtain:

$$\theta_2 = \sin^{-1}\left(\frac{n_2}{n_1}\sin\theta_1\right)$$

Refer to the reference triangle again to obtain:

$$\theta_2 = \sin^{-1}\left(\frac{n_2}{n_1}\frac{n_1}{\sqrt{n_1^2+n_2^2}}\right)$$

$$= \sin^{-1}\left(\frac{n_2}{\sqrt{n_1^2+n_2^2}}\right) = \boxed{\theta_{P2}}$$

Equate these expressions for $n_2 \sin\theta_1$ to obtain:

$$n_1 \sin\theta_P = n_1 \sin\theta_2 \Rightarrow \theta_2 = \boxed{\theta_P}$$

77 •• [SSM] From the data provided in Figure 31-59, calculate the polarization angle for an air–glass interface, using light of wavelength 550 nm in each of the four types of glass shown.

Picture the Problem We can use Brewster's law in conjunction with index of refraction data from Figure 31-59 to calculate the polarization angles for the air-glass interface.

From Brewster's law we have:

$$\theta_p = \tan^{-1}\left(\frac{n_2}{n_1}\right)$$

or, for $n_1 = 1$,

$$\theta_p = \tan^{-1}(n_2)$$

For silicate flint glass, $n_2 \approx 1.62$ and:

$$\theta_{\text{p,silicate flint}} = \tan^{-1}(1.62) = \boxed{58.3°}$$

For borate flint glass, $n_2 \approx 1.57$ and:

$$\theta_{\text{p,borate flint}} = \tan^{-1}(1.57) = \boxed{57.5°}$$

For quartz glass, $n_2 \approx 1.54$ and:

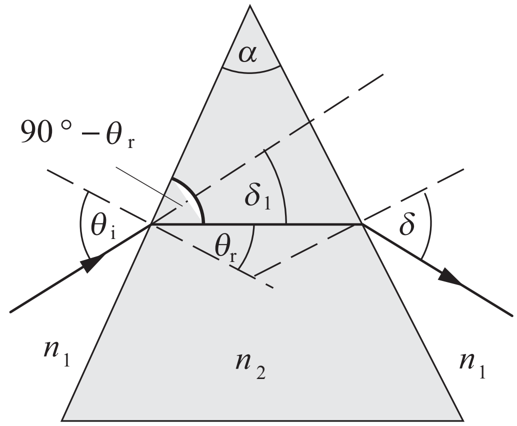
$$\theta_{\text{p, quartz}} = \tan^{-1}(1.54) = \boxed{57.0°}$$

For silicate crown glass, $n_2 \approx 1.51$ and:

$$\theta_{\text{p,silicate crown}} = \tan^{-1}(1.51) = \boxed{56.5°}$$

78 •• A light ray passes through a prism with an apex angle of α, as shown in Figure 31-63. The ray and the bisector of the apex angle bisect at right angles. Show that the *angle of deviation* δ is related to the apex angle and the index of refraction of the prism material by $\sin\left[\frac{1}{2}(\alpha+\delta)\right] = n\sin\left(\frac{1}{2}\alpha\right)$.

Picture the Problem The diagram to the right shows the angles of incidence, refraction, and deviation at the first interface. We can use the geometry of this symmetric passage of the light to express θ_r in terms of α and δ_1 in terms of θ_r and α. We can then use a symmetry argument to express the deviation at the second interface and the total deviation δ. Finally, we can apply Snell's law at the first interface to complete the derivation of the given expression.



With respect to the normal to the left face of the prism, let the angle of incidence be θ_i and the angle of refraction be θ_r. From the geometry of the figure, it is evident that:

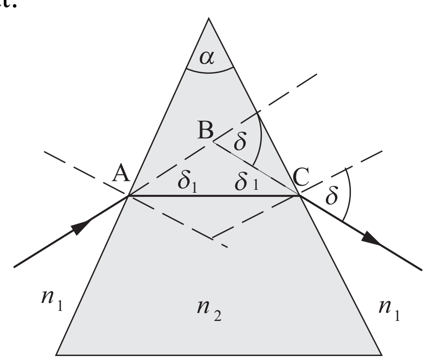
$$\theta_r = \tfrac{1}{2}\alpha$$

Express the angle of deviation at the refracting surface:

$$\delta_1 = \theta_i - \theta_r = \theta_i - \tfrac{1}{2}\alpha$$

Referring to triangle ABC, we see that:

$$\delta = 2\delta_1 = 2\left(\theta_1 - \tfrac{1}{2}\alpha\right) = 2\theta_i - \alpha$$



Solving for θ_i yields:

$$\theta_i = \tfrac{1}{2}(\alpha + \delta)$$

Apply Snell's law, with $n_1 = 1$ and $n_2 = n$, to the first interface:

$$\sin\theta_i = n\sin\tfrac{1}{2}\alpha$$

Substitute for θ_1 to obtain:

$$\boxed{\sin\frac{\alpha+\delta}{2}=n\sin\frac{\alpha}{2}} \quad (1)$$

79 •• **[SSM]** (*a*) For light rays inside a transparent medium that is surrounded by a vacuum, show that the polarizing angle and the critical angle for total internal reflection satisfy $\tan\theta_p = \sin\theta_c$. (*b*) Which angle is larger, the polarizing angle or the critical angle for total internal reflection?

Picture the Problem We can apply Snell's law at the critical angle and the polarizing angle to show that $\tan\theta_p = \sin\theta_c$.

(*a*) Apply Snell's law at the medium-vacuum interface:

$$n_1\sin\theta_1 = n_2\sin\theta_r$$

For $\theta_1 = \theta_c$, $n_1 = n$, and $n_2 = 1$:

$$n\sin\theta_c = \sin 90° = 1$$

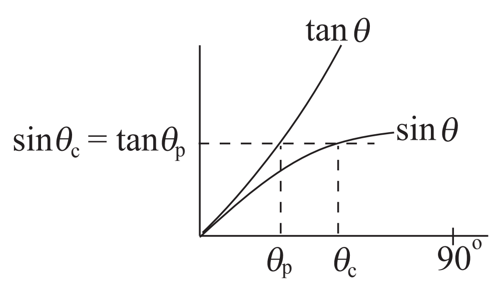
For $\theta_1 = \theta_p$, $n_1 = n$, and $n_2 = 1$:

$$\tan\theta_p = \frac{n_2}{n_1} = \frac{1}{n} \Rightarrow n\tan\theta_p = 1$$

Because both expressions equal one:

$$\boxed{\tan\theta_p = \sin\theta_c}$$

(*b*) For any value of θ:



$$\tan\theta > \sin\theta \Rightarrow \boxed{\theta_c > \theta_p}$$

80 •• Light in air is incident on the surface of a transparent substance at an angle of 58° with the normal. The reflected and refracted rays are observed to be mutually perpendicular. (*a*) What is the index of refraction of the transparent substance? (*b*) What is the critical angle for total internal reflection in this substance?

Picture the Problem Let the numeral 1 refer to the side of the interface from which the light is incident and the numeral 2 to the refraction side of the interface. We can apply Snell's law, under the conditions described in the problem statement, at the interface to derive an expression for n as a function of the angle of incidence (also the polarizing angle).

(*a*) Apply Snell's law at the air-medium interface:

$$\sin\theta_1 = n\sin\theta_2$$

Because the reflected and refracted rays are mutually perpendicular:

$$\theta_1 + \theta_2 = 90° \Rightarrow \theta_2 = 90° - \theta_1$$

Substitute for θ_2 to obtain:

$$\sin\theta_1 = n\sin(90° - \theta_1) = n\cos\theta_1$$

or

$$n = \tan\theta_1 = \tan\theta_p$$

Substitute for θ_p and evaluate n:

$$n = \tan 58° = \boxed{1.6}$$

(*b*) Apply Snell's law at the interface under conditions of total internal reflection:

$$n_2\sin\theta_c = n_1\sin 90° = n_1$$

Because $n_1 = 1$:

$$\theta_c = \sin^{-1}\left(\frac{1}{n_2}\right) = \sin^{-1}\left(\frac{1}{n}\right)$$

Substitute for n and evaluate θ_c:

$$\theta_c = \sin^{-1}\left(\frac{1}{1.6}\right) = \boxed{39°}$$

81 •• A light ray in dense flint glass that has an index of refraction of 1.655 is incident on the glass surface. An unknown liquid condenses on the surface of the glass. Total internal reflection on the glass–liquid interface occurs for a minimum angle of incidence on the glass–liquid interface of 53.7º. (*a*) What is the refractive index of the unknown liquid? (*b*) If the liquid is removed, what is the minimum angle of incidence for total internal reflection? (*c*) For the angle of incidence found in Part (*b*), what is the angle of refraction of the ray into the liquid film? Does a ray emerge from the liquid film into the air above? Assume the glass and liquid have parallel planar surfaces.

Picture the Problem We can apply Snell's law at the glass–liquid and liquid–air interfaces to find the refractive index of the unknown liquid, the minimum angle of incidence (glass-air interface) for total internal reflection, and the angle of refraction of a ray into the liquid film.

(*a*) Apply Snell's law, under critical-angle conditions, at the glass–liquid interface:

$$\sin\theta_c = \frac{n_{liquid}}{n_{glass}} \Rightarrow n_{liquid} = n_{glass}\sin\theta_c$$

Substitute numerical values and evaluate n_{liquid}:

$$n_{\text{liquid}} = (1.655)\sin 53.7° = \boxed{1.33}$$

(*b*) With the liquid removed:

$$\theta_{\text{c}} = \sin^{-1}\left(\frac{1}{n_{\text{glass}}}\right)$$

Substitute numerical values and evaluate θ_{c}:

$$\theta_{\text{c}} = \sin^{-1}\left(\frac{1}{1.655}\right) = \boxed{37.2°}$$

(*c*) Apply Snell's law at the glass–liquid interface:

$$n_{\text{glass}} \sin\theta_1 = n_{\text{liquid}} \sin\theta_2$$

Solve for θ_2:

$$\theta_2 = \sin^{-1}\left[\frac{n_{\text{glass}}}{n_{\text{liquid}}}\sin\theta_1\right]$$

Letting θ_1 be the angle of incidence found in Part (b) yields:

$$\theta_2 = \sin^{-1}\left[\left(\frac{n_{\text{glass}}}{n_{\text{liquid}}}\right)\left(\frac{1}{n_{\text{glass}}}\right)\right] = \sin^{-1}\left(\frac{1}{n_{\text{liquid}}}\right)$$

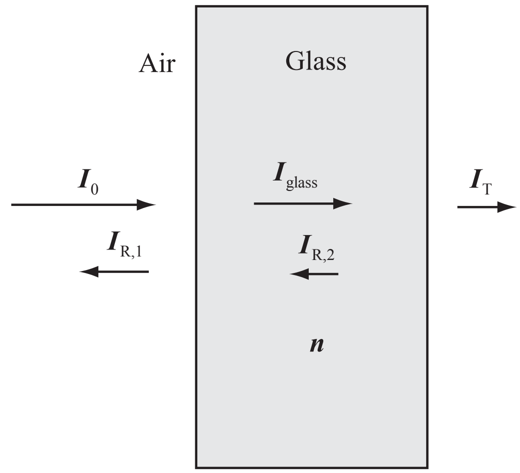
Substitute numerical values and evaluate θ_2:

$$\theta_2 = \sin^{-1}\left(\frac{1}{1.333}\right) = \boxed{48.6°}$$

Because 48.6° is also the angle of incidence at the liquid-air interface and because it is equal to the critical angle for total internal reflection at this interface, no light will emerge into the air.

82 ••• (*a*) Show that for normally incident light, the intensity transmitted through a glass slab that has an index of refraction of *n* and is surrounded by air is approximately given by $I_{\text{T}} = I_0\left[4n/(n+1)^2\right]^2$. (*b*) Use the Part (*a*) result to find the ratio of the transmitted intensity to the incident intensity through *N* parallel slabs of glass for light of normal incidence. (*c*) How many slabs of a glass that has an index of refraction of 1.5 are required to reduce the intensity to 10 percent of the incident intensity?

Picture the Problem We'll neglect multiple reflections at the glass-air interfaces. We can use the expression (Equation 31-7) for the reflected intensity at an interface to express the intensity of the light in the glass slab as the difference between the intensity of the incident beam and the reflected beam. Repeating this analysis at the glass-air interface will lead to the desired result.



(*a*) Express the intensity of the light transmitted into the glass:

$$I_{\text{glass}} = I_0 - I_{\text{R},1}$$

where $I_{\text{R},1}$ is the intensity of the light reflected at the air-glass interface.

The intensity of the light reflected at the air-glass interface is given by Equation 31-7:

$$I_{\text{R},1} = \left(\frac{1-n}{1+n}\right)^2 I_0$$

Substitute and simplify to obtain:

$$I_{\text{glass}} = I_0 - \left(\frac{1-n}{1+n}\right)^2 I_0 = I_0\left[1-\left(\frac{1-n}{1+n}\right)^2\right] = I_0\left[\frac{4n}{(1+n)^2}\right]$$

Express the intensity of the light transmitted at the glass-air interface:

$$I_{\text{T}} = I_{\text{glass}} - I_{\text{R},2}$$

where $I_{\text{R},2}$ is the intensity of the light reflected at the glass-air interface.

The intensity of the light reflected at the glass-air interface is:

$$I_{\text{R},2} = \left(\frac{1-n}{1+n}\right)^2 I_{\text{glass}} = \left(\frac{1-n}{1+n}\right)^2\left[\frac{4n}{(1+n)^2}\right] I_0$$

Substitute and simplify to obtain:

$$\begin{aligned} I_{\mathrm{T}} &= I_0\left[\frac{4n}{(1+n)^2}\right]-\left(\frac{1-n}{1+n}\right)^2\left[\frac{4n}{(1+n)^2}\right]I_0 \\ &= I_0\left[1-\left(\frac{1-n}{1+n}\right)^2\right]\left[\frac{4n}{(1+n)^2}\right] \\ &= I_0\left[\frac{4n}{(1+n)^2}\right]\left[\frac{4n}{(1+n)^2}\right] \\ &= \boxed{I_0\left[\frac{4n}{(1+n)^2}\right]^2} \end{aligned}$$

(b) From Part (a), each slab reduces the intensity by the factor:

$$\left[\frac{4n}{(n+1)^2}\right]^2$$

For N slabs:

$$I_{\mathrm{t}} = I_0\left[\frac{4n}{(n+1)^2}\right]^{2N}$$

and

$$\frac{I_{\mathrm{t}}}{I_0} = \boxed{\left[\frac{4n}{(n+1)^2}\right]^{2N}} \qquad (1)$$

(c) Begin the solution of equation (1) for N by taking the logarithm (arbitrarily to base 10) of both sides of the equation:

$$\begin{aligned} \log\left(\frac{I_{\mathrm{t}}}{I_0}\right) &= \log\left[\frac{4n}{(n+1)^2}\right]^{2N} \\ &= 2N\log\left[\frac{4n}{(n+1)^2}\right] \end{aligned}$$

Solve for N:

$$N = \frac{\log\left(\frac{I_{\mathrm{t}}}{I_0}\right)}{2\log\left[\frac{4n}{(n+1)^2}\right]}$$

Substitute numerical values and evaluate N:

$$N = \frac{\log(0.1)}{2\log\left[\frac{4(1.5)}{(1.5+1)^2}\right]} = 28.2 \approx \boxed{28}$$

83 ••• Equation 31-14 gives the relation between the angle of deviation ϕ_d of a light ray incident on a spherical drop of water in terms of the incident angle θ_1 and the index of refraction of water. (*a*) Assume that $n_{air} = 1$, and derive an expression for $d\phi_d/d\theta_1$. *Hint:* If $y = \sin^{-1} x$, then $dy/dx = (1 - x^2)^{-1/2}$. (*b*) Use this result to show that the angle of incidence for minimum deviation θ_{1m} is given by $\cos\theta_{1m} = \sqrt{\frac{1}{3}(n^2 - 1)}$. (*c*) The index of refraction for a certain red light in water is 1.3318 and that the index of refraction for a certain blue light in water is 1.3435. Use the result of Part (*a*) to find the angular separation of these colors in the primary rainbow.

Picture the Problem (*a*) We can follow the directions given in the problem statement and use the hint to establish the given result. (*b*) Treating the result of Part (*a*) as an extreme-value problem will lead to the given result. (*c*) We can use Equation 31-14 and the result of Part (*b*) to find the angular separation of these colors in the primary rainbow.

(*a*) Equation 31-14 is:

$$\phi_d = \pi + 2\theta_1 - 4\sin^{-1}\left(\frac{n_{air}\sin\theta_1}{n_{water}}\right)$$

For $n_{air} = 1$ and $n_{water} = n$:

$$\phi_d = \pi + 2\theta_1 - 4\sin^{-1}\left(\frac{\sin\theta_1}{n}\right)$$

Use the hint to differentiate ϕ_d with respect to θ_1:

$$\frac{d\phi_d}{d\theta_1} = \frac{d}{d\theta_1}\left[\pi + 2\theta_1 - 4\sin^{-1}\left(\frac{\sin\theta_1}{n}\right)\right]$$

$$= \boxed{2 - \frac{4\cos\theta_1}{\sqrt{n^2 - \sin^2\theta_1}}}$$

(*b*) Set $d\phi_d/d\theta_1 = 0$:

$$2 - \frac{4\cos\theta_1}{\sqrt{n^2 - \sin^2\theta_1}} = 0 \text{ for extrema}$$

Simplify to obtain:

$$16\cos^2\theta_1 = 4\left(n^2 - \sin^2\theta_1\right)$$

Replace $\sin^2\theta_1$ with $1 - \cos^2\theta_1$ and simplify to obtain:

$$12\cos^2\theta_1 = 4n^2 - 4$$

Solve for $\cos\theta_1 = \cos\theta_{1m}$:

$$\cos\theta_{1m} = \boxed{\sqrt{\frac{n^2 - 1}{3}}}$$

(*c*) Express the angular separation $\Delta\phi$ of blue and red:

$$\Delta\phi = \phi_{\text{d,blue}} - \phi_{\text{d,red}} \tag{1}$$

From Equation 31-18, with $n_{\text{air}} = 1$ and $n_{\text{water}} = n$:

$$\phi_{\text{d}} = \pi + 2\theta_1 - 4\sin^{-1}\left(\frac{\sin\theta_1}{n}\right)$$

From Part (*b*):

$$\theta_{1\text{m}} = \cos^{-1}\left[\sqrt{\frac{n^2-1}{3}}\right]$$

Substitute to obtain:

$$\phi_{\text{d}} = \pi + 2\cos^{-1}\left[\sqrt{\frac{n^2-1}{3}}\right] - 4\sin^{-1}\left(\frac{\sin\left\{\cos^{-1}\left[\sqrt{\frac{n^2-1}{3}}\right]\right\}}{n}\right)$$

Evaluate ϕ_{d} for blue light in water:

$$\phi_{\text{d,blue}} = \pi + 2\cos^{-1}\left[\sqrt{\frac{(1.3435)^2-1}{3}}\right] - 4\sin^{-1}\left(\frac{\sin\left\{\cos^{-1}\left[\sqrt{\frac{(1.3435)^2-1}{3}}\right]\right\}}{1.3435}\right)$$

$$= 139.42^\circ$$

Evaluate ϕ_{d} for red light in water:

$$\phi_{\text{d,red}} = \pi + 2\cos^{-1}\left[\sqrt{\frac{(1.3318)^2-1}{3}}\right] - 4\sin^{-1}\left(\frac{\sin\left\{\cos^{-1}\left[\sqrt{\frac{(1.3318)^2-1}{3}}\right]\right\}}{1.3318}\right)$$

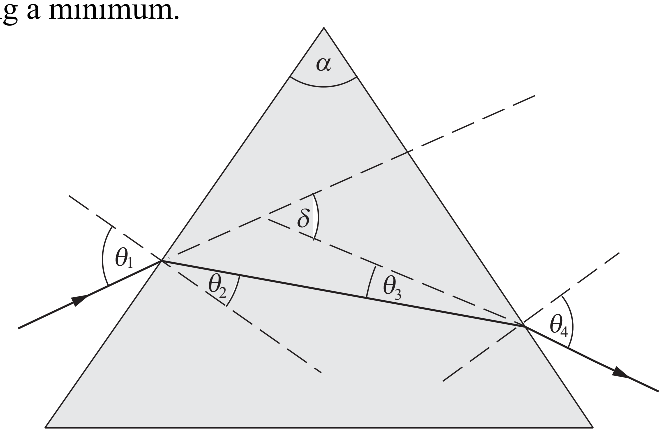
$$= 137.75^\circ$$

Substitute numerical values in equation (1) and evaluate $\Delta\phi$:

$$\Delta\phi = 139.42 - 137.75° = \boxed{1.67°}$$

84 ••• Show that the angle of deviation δ is a minimum if the angle of incidence is such that the ray and the bisector of the apex angle α (Figure 31-62) intersect at right angles.

Picture the Problem The figure below shows the prism and the path of the ray through it. The dashed lines are the normals to the prism faces. The triangle formed by the interior ray and the prism faces has interior angles of α, 90° − θ_2, and 90° − θ_3. Consequently, $\theta_2 + \theta_3 = \alpha$. We can apply Snell's law at both interfaces to express the angle of deviation δ as a function of θ_3 and then set the derivative of this function equal to zero to find the conditions on θ_3 and θ_2 that result in δ being a minimum.



Express the angle of deviation:

$$\delta = \theta_1 + \theta_2 - \alpha \qquad (1)$$

Apply Snell's law to relate θ_1 to θ_2 and θ_3 to θ_4:

$$\sin\theta_1 = n\sin\theta_2 \qquad (2)$$

and

$$n\sin\theta_3 = \sin\theta_4 \qquad (3)$$

Solve equation (2) for θ_1 and equation (3) for θ_4:

$$\theta_1 = \sin^{-1}(n\sin\theta_2)$$

and

$$\theta_4 = \sin^{-1}(n\sin\theta_3)$$

Substitute in equation (1) to obtain:

$$\delta = \sin^{-1}(n\sin\theta_2) + \sin^{-1}(n\sin\theta_3) - \alpha = \sin^{-1}[n\sin(\theta_3 - \alpha)] + \sin^{-1}(n\sin\theta_3) - \alpha$$

Note that the only variable in this expression is θ_3. To determine the condition that minimizes δ, take the derivative of δ with respect to θ_3 and set it equal to zero.

$$\frac{d\delta}{d\theta_3}=\frac{d}{d\theta_3}\left\{\sin^{-1}\left[n\sin(\theta_3-\alpha)\right]+\sin^{-1}(n\sin\theta_3)-\alpha\right\}$$

$$=-\frac{n\cos(\alpha-\theta_3)}{\sqrt{1-\left[n\sin(\alpha-\theta_3)\right]^2}}+\frac{n\cos\theta_3}{\sqrt{1-(n\sin\theta_3)^2}}=0 \text{ for extrema}$$

This equation is satisfied provided: $\alpha-\theta_3=\theta_3 \Rightarrow \theta_3=\frac{1}{2}\alpha$

Because $\theta_2=\alpha-\theta_3$: $\theta_2=\alpha-\frac{1}{2}\alpha=\frac{1}{2}\alpha$

Because $\boldsymbol{\theta}_2=\boldsymbol{\theta}_3$, we can conclude that the deviation angle is a minimum if the ray p through the prism symmetrically.

Remarks: Setting $d\delta/d\theta_3$ = 0 establishes the condition on θ_3 that δ is either a maximum or a minimum. To establish that δ is indeed a minimum when $\theta_3=\theta_2=\frac{1}{2}\alpha$, we can either show that $d^2\delta/d\theta_3^2$, evaluated at $\theta_3=\frac{1}{2}\alpha$, is positive or, alternatively, plot a graph of $\delta(\theta_3)$ to show that it is concave upward at $\theta_3=\frac{1}{2}\alpha$.

Chapter 32
Optical Images

Conceptual Problems

1 • Can a virtual image be photographed? If so, give an example. If not, explain why.

Determine the Concept Yes. Note that a virtual image is "seen" because the eye focuses the diverging rays to form a real image on the retina. For example, you can photograph the virtual image of yourself in a flat mirror and get a perfectly good picture.

2 • Suppose the *x*, *y*, and *z* axes of a 3-D coordinate system are painted a different color. One photograph is taken of the coordinate system and another is taken of its image in a plane mirror. Is it possible to tell that one of the photographs is of a mirror image? Or could both photographs be of the real coordinate system from different angles?

Determine the Concept Yes; the coordinate system and its mirror image will have opposite handedness. That is, if the coordinate system is a right-handed coordinate system, then the mirror image will be a left-handed coordinate system, and vice versa.

3 • **[SSM]** True or False

(*a*) The virtual image formed by a concave mirror is always smaller than the object.
(*b*) A concave mirror always forms a virtual image.
(*c*) A convex mirror never forms a real image of a real object.
(*d*) A concave mirror never forms an enlarged real image of an object.

(*a*) False. The size of the virtual image formed by a concave mirror when the object is between the focal point and the vertex of the mirror depends on the distance of the object from the vertex and is always larger than the object.

(*b*) False. When the object is outside the focal point, the image is real.

(*c*) True.

(*d*) False. When the object is between the center of curvature and the focal point, the image is enlarged and real.

4 • An ant is crawling along the axis of a convex mirror that has a radius of curvature *R*. At what object distances, if any, will the mirror produce (*a*) an upright image, (*b*) a virtual image, (*c*) an image smaller than the object, and (*d*) an image larger than the object?

Determine the Concept Let *s* be the object distance and *f* the focal length of the mirror.

(*a*) If $s < \frac{1}{2}R$, the image is virtual, upright, and larger than the object.

(*b*) If $s < \frac{1}{2}R$, the image is virtual, upright, and larger than the object.

(*c*) If $s > R$, the image is real, inverted, and smaller than the object.

(*d*) If $\frac{1}{2}R < s < R$, the image is real, inverted, and larger than the object.

5 • [SSM] An ant is crawling along the axis of a concave mirror that has a radius of curvature *R*. At what object distances, if any, will the mirror produce (*a*) an upright image, (*b*) a virtual image, (*c*) an image smaller than the object, and (*d*) an image larger than the object?

Determine the Concept
(*a*) The mirror will produce an upright image for all object distances.

(*b*) The mirror will produce a virtual image for all object distances.

(*c*) The mirror will produce an image that is that is smaller than the object for all object distances.

(*d*) The mirror will never produce an enlarged image.

6 •• Convex mirrors are often used for rearview mirrors on cars and trucks to give a wide-angle view. "Warning, objects are closer than they appear." is written below the mirrors. Yet, according to a ray diagram, the image distance for distant objects is much shorter than the object distance. Why then do they appear more distant?

Determine the Concept They appear more distant because in a convex mirror the angular sizes of the images are smaller than they would be in a flat mirror. The angular size of the image is $\dfrac{y'}{|s'|+L}$, where y' is the height of the image, s' is the distance between the image and the mirror, and L is the distance between the observer and the mirror. For a flat mirror, $y' = y$ and $s' = -s$.

We wish to prove that, for a convex mirror:

$$\frac{y'}{|s'|+L} < \frac{y}{s+L} \qquad (1)$$

If equation (1) is valid, then:

$$\frac{|s'|+L}{y'} > \frac{s+L}{y}$$

or

$$\frac{|s'|}{y'} + \frac{L}{y'} > \frac{s}{y} + \frac{L}{y} \qquad (2)$$

Because the lateral magnification is $m = \frac{y'}{y} = -\frac{s'}{s}$:

$$\frac{y'}{|s'|} = \frac{y}{s} \qquad (3)$$

Combining this with equation (2) yields:

$$\frac{L}{y'} > \frac{L}{y} \Rightarrow y' < y \qquad (4)$$

It follows that, if $y' < y$, then:

$$|s'| < s$$

To show that $|s'| < s$ we begin with the mirror equation:

$$\frac{1}{s'} + \frac{1}{s} = \frac{1}{f}$$

Solving for s' yields:

$$s' = s\frac{f}{s-f}$$

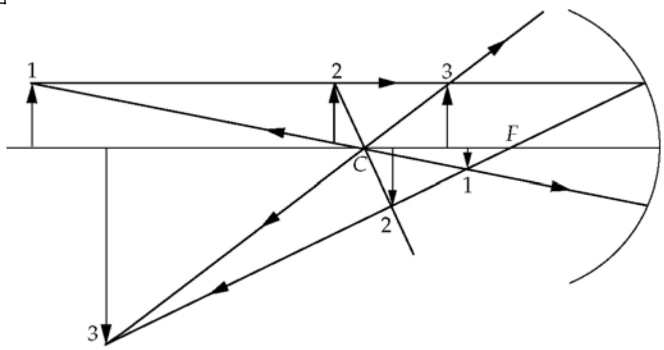
Because f is negative and s is positive:

$$|s'| = s\frac{|f|}{s+|f|} \Rightarrow |s'| < s$$

Thus, we have proven that, if equation (1) is valid, then equation (4) is valid. To prove that equation 1 is valid, we merely follow this proof in reverse order.

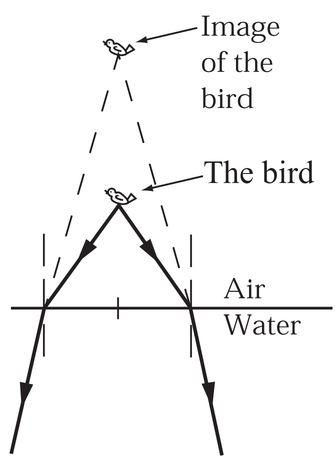
7 • As an ant on the axis of a concave mirror crawls from a great distance to the focal point of a concave mirror, the image of the ant moves from (*a*) a great distance toward the focal point and is always real, (*b*) the focal point to a great distance from the mirror and is always real, (*c*) the focal point to the center of curvature of the mirror and is always real, (*d*) the focal point to a great distance from the mirror and changes from a real image to a virtual image.

Picture the Problem The ray diagram shows three object positions 1, 2, and 3 as the moves from a great distance to the focal point F of a concave mirror. The real images corresponding to each of these object positions are labeled with the same numeral. $\boxed{(b)}$ is correct.



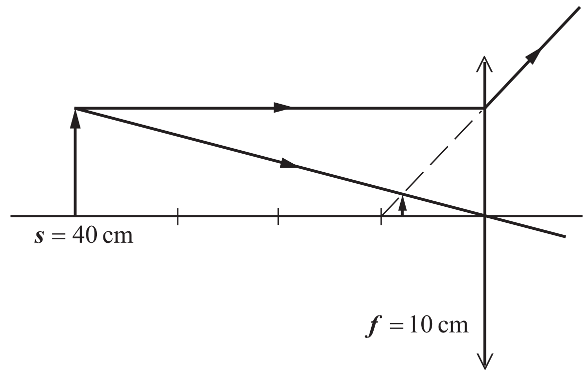
8 • A kingfisher bird that is perched on a branch a few feet above the water is viewed by a scuba diver submerged beneath the surface of the water directly below the bird. Does the bird appear to the diver to be closer to or farther from the surface than the actual bird? Explain your answer using a ray diagram.

Picture the Problem The diagram shows two rays (from the bundle of rays) of light refracted at the air-water interface. Because the index of refraction of water is greater than that of air, the rays are bent toward the normal. The diver will, therefore, think that the rays are diverging from a point above the bird and so the bird appears to be farther from the surface than it actually is.



9 • An object is placed on the axis of a diverging lens whose focal length has a magnitude of 10 cm. The distance from the object to the lens is 40 cm. The image is (a) real, inverted, and diminished, (b) real, inverted, and enlarged, (c) virtual, inverted, and diminished, (d) virtual, upright, and diminished, (e) virtual, upright, and enlarged.

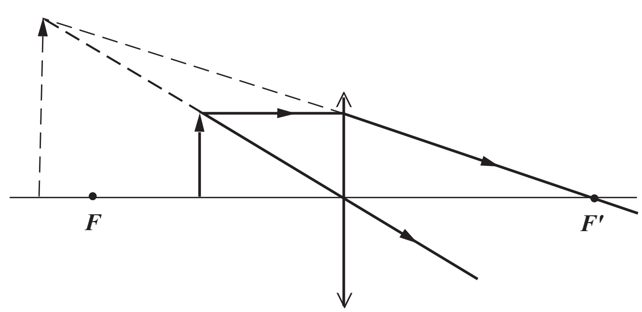
Picture the Problem We can use a ray diagram to determine the general features of the image. In the diagram shown, the parallel ray and central ray have been used to locate the image.



From the diagram, we see that the image is virtual (only one of the rays from the head of the object actually pass through the head of the image), upright, and diminished. $\boxed{(d)}$ is correct.

10 •• If an object is placed between the focal point of a converging lens and the optical center of the lens, the image is (*a*) real, inverted, and enlarged, (*b*) virtual, upright, and diminished, (*c*) virtual, upright, and enlarged, (*d*) real, inverted, and diminished.

Picture the Problem We can use a ray diagram to determine the general features of the image. In the diagram shown, the ray parallel to the principle axis and the central ray have been used to locate the image. Note that the object has been placed farther to the right than suggested in the problem statement. This was done so that the image would not be so large and so far to the left as to make the diagram excessively large.



From the diagram, we see that the image is virtual (neither ray from the head of the object passes through the head of the image), upright, and enlarged. $\boxed{(c)}$ is correct.

11 • A converging lens is made of glass that has an index of refraction of 1.6. When the lens is in air, its focal length is 30 cm. When the lens is immersed in water, its focal length (*a*) is greater than 30 cm, (*b*) is between zero and 30 cm, (*c*) is equal to 30 cm, (*d*) has a negative value.

Picture the Problem We can apply the lens maker's equation to the air-glass lens and to the water-glass lens to find the ratio of their focal lengths.

Apply the lens maker's equation to the air-glass interface:

$$\frac{1}{f_{\text{air}}}=(1.6-1)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

Apply the lens maker's equation to the water-glass interface:

$$\frac{1}{f_{\text{water}}}=(1.6-1.33)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

Divide the first of these equations by the second to obtain:

$$\frac{f_{\text{water}}}{f_{\text{air}}}=\frac{(1.6-1)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)}{(1.6-1.33)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)}=2.2$$

or $f_{\text{water}}=2.2\,f_{\text{air}}$ and $\boxed{(a)}$ is correct.

12 • True or false:

(*a*) A virtual image cannot be displayed on a screen.
(*b*) A negative image distance implies that the image is virtual.
(*c*) All rays parallel to the axis of a spherical mirror are reflected through a single point.
(*d*) A diverging lens cannot form a real image from a real object.
(*e*) The image distance for a converging lens is always positive.

(*a*) True.

(*b*) True.

(*c*) False. Where the rays intersect the axis of a spherical mirror depends on how far from the axis they are reflected from the mirror.

(*d*) True.

(*e*) False. The image distance for a virtual image is negative.

13 • Both the human eye and the digital camera work by forming real images on light-sensitive surfaces. The eye forms a real image on the retina and the camera forms a real image on a CCD array. Explain the difference between the ways in which these two systems *accommodate*. That is, the difference between how an eye adjusts and how a camera adjusts (or can be adjusted) to form a focused image for objects at both large and short distances from the camera.

Determine the Concept The muscles in the eye change the thickness of the lens and thereby change the focal length of the lens to accommodate objects at different distances. A camera lens, on the other hand, has a fixed focal length so that focusing is accomplished by varying the distance between the lens and the light-sensitive surface.

14 • If an object is 25 cm in front of the naked eye of a farsighted person, an image (*a*) would be formed behind the retina if it were not for the fact that that the light is blocked (by the back of the eyeball) and the corrective contact lens should be convex, (*b*) would be formed behind the retina if it were not for the fact that that the light is blocked (by the back of the eyeball) and the corrective contact lens should be concave, (*c*) is formed in front of the retina and the corrective contact lens should be convex, (*d*) is formed in front of the retina and the corrective contact lens should be concave.

Determine the Concept The eye muscles of a farsighted person lack the ability to shorten the focal length of the lens in the eye sufficiently to form an image on the retina of the eye. A convex lens (a lens that is thicker in the middle than at the circumference) will bring the image forward onto the retina. $\boxed{(a)}$ is correct.

15 •• Explain the following statement: A microscope is an object magnifier, but a telescope is an angle magnifier. *Hint: Take a look at the ray diagram for each magnifier and use it to explain the difference in adjectives.*

Determine the Concept The objective lens of a microscope ordinarily produces an image that is larger than the object being viewed, and that image is angularly magnified by the eyepiece. The objective lens of a telescope, on the other hand, ordinarily produces an image that is smaller than the object being viewed (see Figure 32-52), and that image is angularly magnified by the eyepiece. The telescope never produces a real image that is larger than the object.

Estimation and Approximation

16 • Estimate the location and size of the image of your face when you hold a shiny new tablespoon a foot in front of your face and with the convex side toward you.

Picture the Problem We can model the spoon as a convex spherical mirror and use the mirror equation and the lateral magnification equation to estimate the location and size of the image of your face.

The mirror equation is: $$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$$

Because $f = r/2$, where r is the radius of curvature of the mirror:

$$\frac{1}{s}+\frac{1}{s'}=\frac{2}{r}\Rightarrow s'=\frac{rs}{r-2s}$$

Let the distance from your face to the surface of the spoon be 15 cm. If the radius of curvature of the spoon is 2 cm, then:

$$s'=\frac{(2.0\text{ cm})(15\text{ cm})}{2.0\text{ cm}-2(15\text{ cm})}\approx -1.1\text{ cm}$$

or $\boxed{\text{about } 1.1\text{ cm behind the spoon}}$

The lateral magnification equation is:

$$m=\frac{y'}{y}=-\frac{s'}{s}\Rightarrow y'=-\left(\frac{s'}{s}\right)y$$

Assume your face is 25 cm long. Substitute numerical values and evaluate y':

$$y'=-\left(\frac{-1.1\text{ cm}}{15\text{ cm}}\right)(25\text{ cm})$$

$$\approx \boxed{2\text{ cm}}$$

17 • Estimate the focal length of the ″mirror″ produced by the surface of the water in the reflection pools in front of the Lincoln Memorial on a still night.

Determine the Concept The surface of the ″mirror″ produced by the surface of the water in the Lincoln Memorial reflecting pool is approximately spherical with a radius of curvature approximately equal to the radius of Earth. The focal length of a spherical mirror is half its radius of curvature. Hence $f = \boxed{\tfrac{1}{2}R_{\text{Earth}}}$

18 •• Estimate the maximum value that could be obtained for the magnifying power of a simple magnifier, using Equation 32-20. *Hint: Think about the smallest focal length lens that could be made from glass and still be used as a magnifier*.

Picture the Problem Because the focal length of a spherical lens depends on its radii of curvature and the magnification depends on the focal length, there is a practical upper limit to the magnification.

Use Equation 32-20 to relate the magnification M of a simple magnifier to its focal length f:

$$M=\frac{x_{\text{np}}}{f}$$

Use the lens-maker's equation to relate the focal length of a lens to its radii of curvature and the index of refraction of the material from which it is constructed:

$$\frac{1}{f}=(n-1)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

For a plano-convex lens, $r_2 = \infty$. Hence:

$$\frac{1}{f} = \frac{n-1}{r_1} \Rightarrow f = \frac{r_1}{n-1}$$

Substitute in the expression for M and simplify to obtain:

$$M = \frac{(n-1)x_{\text{np}}}{r_1}$$

Note that the smallest reasonable value for r_1 will maximize M.

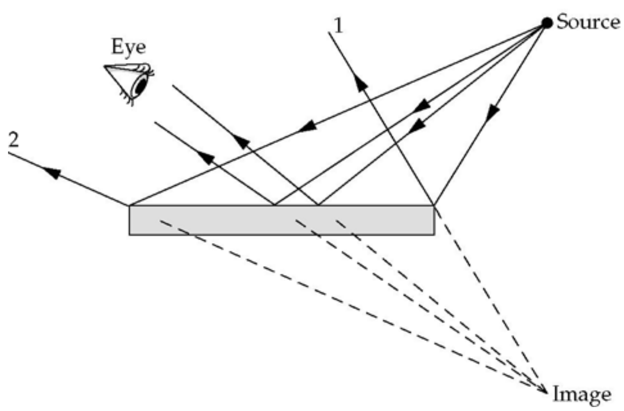
A reasonable smallest value for the radius of a magnifier is 1.0 cm. Use this value and $n = 1.5$ to estimate M_{max}:

$$M_{\text{max}} = \frac{(1.5-1)(25\,\text{cm})}{1.0\,\text{cm}} = \boxed{13}$$

Plane Mirrors

19 • **[SSM]** The image of the object point P in Figure 32-57 is viewed by an eye, as shown. Draw rays from the object point that reflect from the mirror and enter the eye. If the object point and the mirror are fixed in their locations, indicate the range of locations where the eye can be positioned and still see the image of the object point.

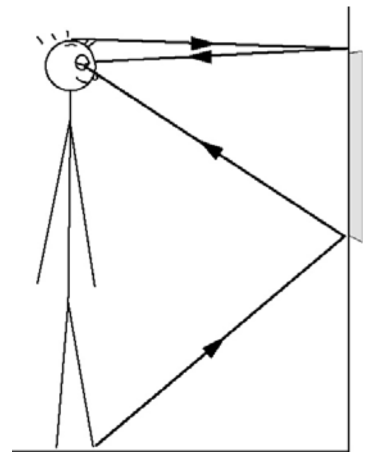
Determine the Concept Rays from the source that are reflected by the mirror are shown in the following diagram. The reflected rays appear to diverge from the image. The eye can see the image if it is in the region between rays 1 and 2.



20 • You are 1.62 m tall and want to be able to see your full image in a vertical plane mirror. (a) What is the minimum height of the mirror that will meet your needs? (b) How far above the floor should the bottom of mirror in (a) be placed, assuming that the top of your head is 14 cm above your eye level? Use a ray diagram to explain your answer.

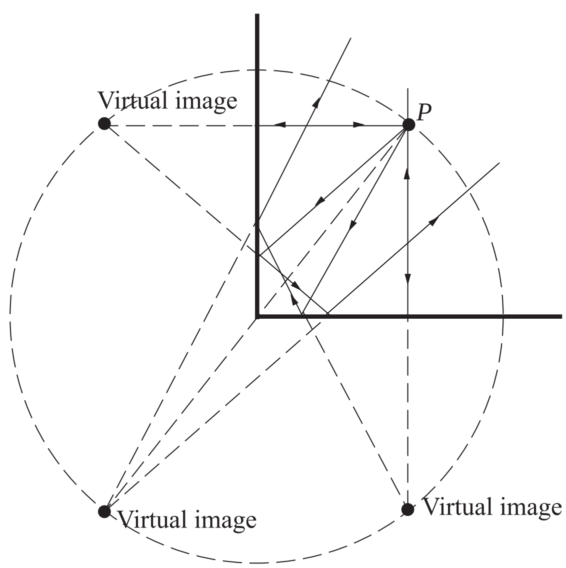
Determine the Concept A ray diagram showing rays from your feet and the top of your head reaching your eyes is shown to the right. (*a*) The mirror must be half your height, i.e., $\boxed{81\,\text{cm}}$

(*b*) The top of the minimum-height mirror must be 7 cm below the top of your head, or 155 cm above the floor. The bottom of the mirror should be placed $155\,\text{cm} - 81\,\text{cm} = \boxed{74\,\text{cm}}$ above the floor.



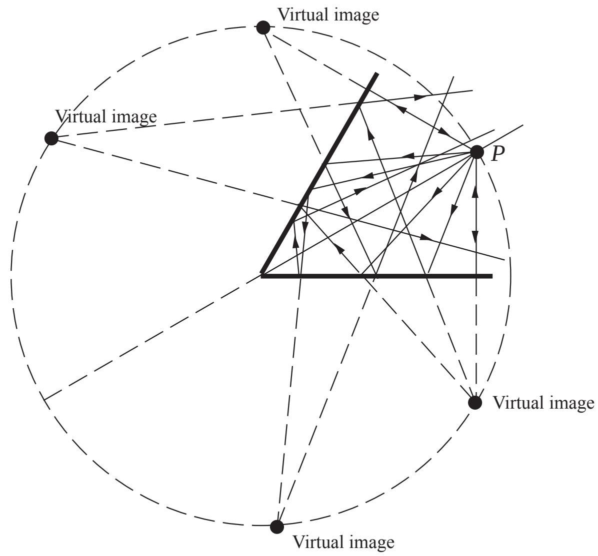
21 •• [SSM] (*a*) Two plane mirrors make an angle of 90º. The light from a point object that is arbitrarily positioned in front of the mirrors produces images at three locations. For each image location, draw two rays from the object that, after one or two reflections, appear to come from the image location. (*b*) Two plane mirrors make an angle of 60º with each other. Draw a sketch to show the location of all the images formed of an object on the bisector of the angle between the mirrors. (*c*) Repeat Part (*b*) for an angle of 120º.

Determine the Concept
(*a*) Draw rays of light from the object (*P*) that satisfy the law of reflection at the two mirror surfaces. Three virtual images are formed, as shown in the following figure. The eye should be to the right and above the mirrors in order to see these images.

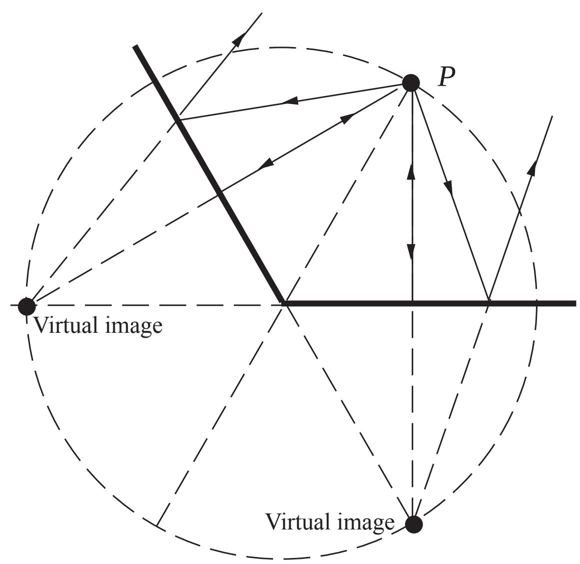


(*b*) The following diagram shows selected rays emanating from a point object (*P*) located on the bisector of the 60° angle between the mirrors. These rays form the two virtual images below the horizontal mirror. The construction details for the

two virtual images behind the mirror that is at an angle of 60° with the horizontal mirror have been omitted due to the confusing detail their inclusion would add to the diagram.



(c) The following diagram shows selected rays emanating from a point object (P) on the bisector of the 120° angle between the mirrors. These rays form the two virtual images at the intersection of the dashed lines (extensions of the reflected rays):



22 •• Show that the mirror equation (Equation 32-4 where $f = r/2$) yields the correct image distance and magnification for a plane mirror.

Picture the Problem We can use Equation 32-4 and the definition of the lateral magnification of an image to show that the mirror equation yields the correct image distance and magnification for a plane mirror.

The mirror equation is: $$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$$

Because $f=r/2$: $$\frac{1}{s}+\frac{1}{s'}=\frac{2}{r}$$

For a plane mirror, $r=\infty$. Hence: $$\frac{1}{s}+\frac{1}{s'}=0 \Rightarrow s'=\boxed{-s}$$

The lateral magnification of the image is given by: $$M=-\frac{s'}{s}=-\frac{-s}{s}=\boxed{+1}$$

23 •• When two plane mirrors are parallel, such as on opposite walls in a barber shop, multiple images arise because each image in one mirror serves as an object for the other mirror. An object is placed between parallel mirrors separated by 30 cm. The object is 10 cm in front of the left mirror and 20 cm in front of the right mirror. (*a*) Find the distance from the left mirror to the first four images in that mirror. (*b*) Find the distance from the right mirror to the first four images in that mirror. (*c*) Explain why each more distant image becomes fainter and fainter.

Determine the Concept (*a*) The first image in the mirror on the left is 10 cm behind the mirror. The mirror on the right forms an image 20 cm behind that mirror or 50 cm from the left mirror. This image will result in a second image 50 cm behind the left mirror. The first image in the left mirror is 40 cm from the right mirror and forms an image 40 cm behind the right mirror or 70 cm from the left mirror. That image gives an image 70 cm behind the left mirror. The fourth image behind the left mirror is 110 cm behind that mirror.

(*a*) For the mirror on the left, the images are located 10 cm, 50 cm, 70 cm, and 110 cm behind the mirror on the left

(*b*) For the mirror on the right, the images are located 20 cm, 40 cm, 80 cm, and 100 cm behind the mirror on the right.

(*c*) The successive images are dimmer because the light travels farther to form them. The intensity falls of inversely with the square of the distance the light travels. In addition, at each reflection a small percentage of the light intensity is lost. Real mirrors are not 100% reflecting.

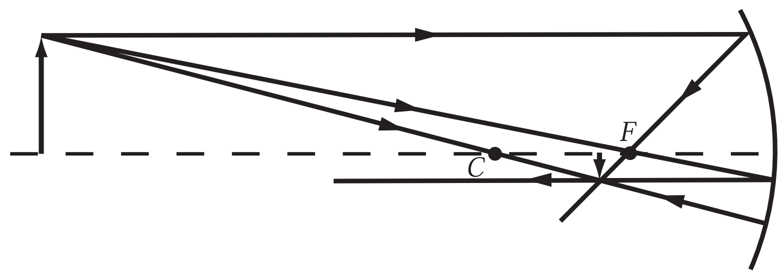
Spherical Mirrors

24 • A concave mirror has a radius of curvature equal to 24 cm. Use ray diagrams to locate the image, if it exists, for an object near the axis at distances of

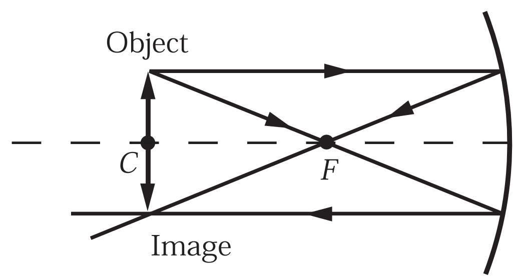
(*a*) 55 cm, (*b*) 24 cm, (*c*) 12 cm, and (*d*) 8.0 cm from the mirror. For each case, state whether the image is real or virtual; upright or inverted; and enlarged, reduced, or the same size as the object.

Picture the Problem The easiest rays to use in locating the image are (1) the ray parallel to the principal axis and passes through the focal point of the mirror, (2) the ray that passes through the center of curvature of the spherical mirror and is reflected back on itself, and (3) the ray that passes through the focal point of the spherical mirror and is reflected parallel to the principal axis. We can use any two of these rays emanating from the top of the object to locate the image of the object.

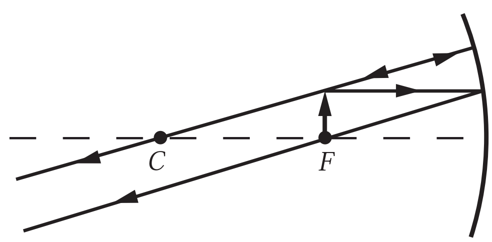
(*a*) The ray diagram follows. The image is real, inverted, and reduced.



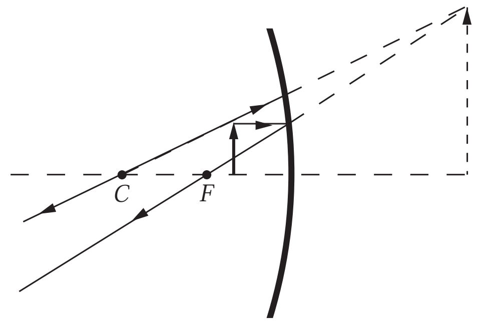
(*b*) The ray diagram is shown to the right. The image is real, inverted, and the same size as the object.



(*c*) The ray diagram is shown to the right. The object is at the focal plane of the mirror. The emerging rays are parallel and do not form an image.



(*d*) The ray diagram is shown to the right. The image is virtual, erect, and enlarged.



25 • **[SSM]** (*a*) Use the mirror equation (Equation 32-4 where $f = r/2$) to calculate the image distances for the object distances and mirror of Problem 24. (*b*) Calculate the magnification for each given object distance.

Picture the Problem In describing the images, we must indicate where they are located, how large they are in relationship to the object, whether they are real or virtual, and whether they are upright or inverted. The object distance *s*, the image distance *s*′, and the focal length of a mirror are related according to $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, where $f = \frac{1}{2}r$ and *r* is the radius of curvature of the mirror. In this problem, $f = 12$ cm because *r* is positive for a concave mirror.

(*a*) Solve the mirror equation for *s*′:

$$s' = \frac{fs}{s-f} \text{ where } \boldsymbol{f} = \frac{\boldsymbol{r}}{2}$$

When $s = 55$ cm:

$$s' = \frac{(12\,\text{cm})(55\,\text{cm})}{55\,\text{cm} - 12\,\text{cm}} = 15.35\,\text{cm}$$

$$= \boxed{15\,\text{cm}}$$

When $s = 24$ cm:

$$s' = \frac{(12\,\text{cm})(24\,\text{cm})}{24\,\text{cm} - 12\,\text{cm}} = \boxed{24\,\text{cm}}$$

When $s = 12$ cm:

$$s' = \frac{(12\,\text{cm})(12\,\text{cm})}{12\,\text{cm} - 12\,\text{cm}} \boxed{\text{is undefined}}$$

When $s = 8.0$ cm:

$$s' = \frac{(12\,\text{cm})(8.0\,\text{cm})}{8.0\,\text{cm} - 12\,\text{cm}} = -24.0\,\text{cm}$$

$$= \boxed{-0.2\,\text{m}}$$

(*b*) The lateral magnification of the image is:

$$m=-\frac{s'}{s}$$

When $s = 55$ cm, the lateral magnification of the image is:

$$m=-\frac{s'}{s}=-\frac{15.35\,\text{cm}}{55\,\text{cm}}=\boxed{-0.28}$$

When $s = 24$ cm, the lateral magnification of the image is:

$$m=-\frac{s'}{s}=-\frac{24\,\text{cm}}{24\,\text{cm}}=\boxed{-1.0}$$

When $s = 12$ cm:

$$\boxed{m \text{ is undefined.}}$$

When $s = 8.0$ cm, the lateral magnification of the image is:

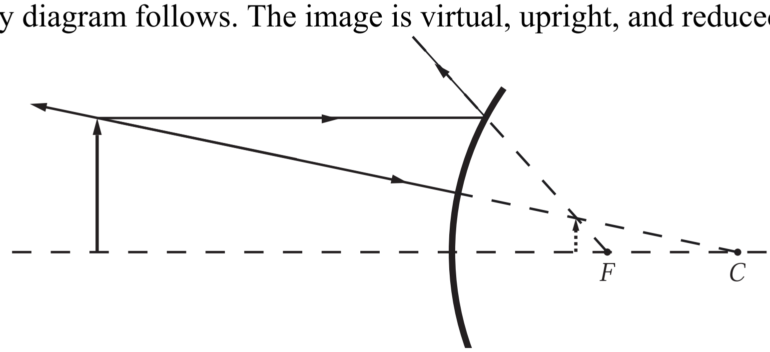
$$m=-\frac{s'}{s}=-\frac{-24\,\text{cm}}{8.0\,\text{cm}}=\boxed{3.0}$$

Remarks: These results are in excellent agreement with those obtained graphically in Problem 24.

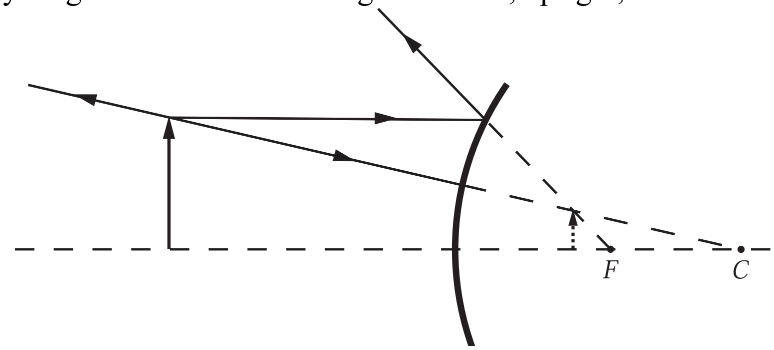
26 • A convex mirror has a radius of curvature that has a magnitude equal to 24 cm. Use ray diagrams to locate the image, if it exists, for an object near the axis at distances of (*a*) 55 cm, (*b*) 24 cm, (*c*) 12 cm, (*d*) 8.0 cm, (*e*) 1.0 cm from the mirror. For each case, state whether the image is real or virtual; upright or inverted; and enlarged, reduced, or the same size as the object.

Picture the Problem The easiest rays to use in locating the image are (1) the ray parallel to the principal axis and passes through the focal point of the mirror, (2) the ray that passes through the center of curvature of the spherical mirror and is reflected back on itself, and (3) the ray that passes through the focal point of the spherical mirror and is reflected parallel to the principal axis. We can use any two of these rays emanating from the top of the object to locate the image of the object. Note that, due to space limitations, the following ray diagrams are not to the same scale as those in Problem 24.

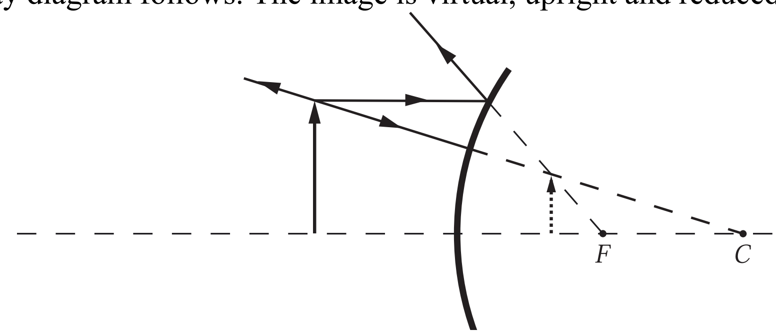
(*a*) The ray diagram follows. The image is virtual, upright, and reduced.



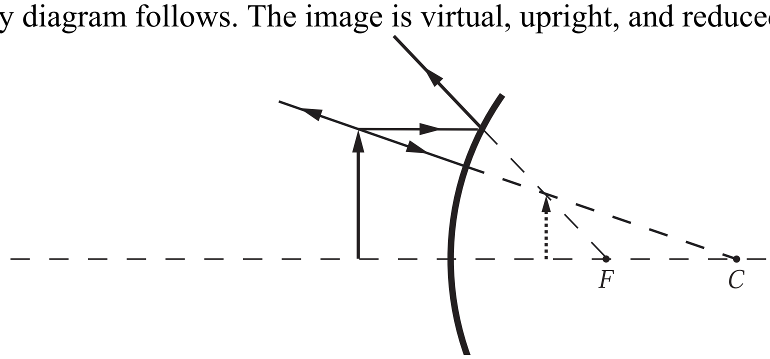
(*b*) The ray diagram follows. The image is virtual, upright, and reduced.



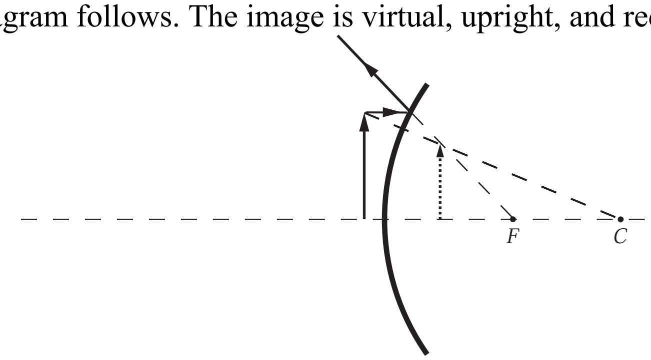
(*c*) The ray diagram follows. The image is virtual, upright and reduced.



(*d*) The ray diagram follows. The image is virtual, upright, and reduced.



(*e*) The ray diagram follows. The image is virtual, upright, and reduced.



27 • (*a*) Use the mirror equation (Equation 32-4 where $f = r/2$) to calculate the image distances for the object distances and mirror of Problem 26.
(*b*) Calculate the magnification for each given object distance.

Picture the Problem In describing the images, we must indicate where they are located, how large they are in relationship to the object, whether they are real or virtual, and whether they are upright or inverted. The object distance *s*, the image distance *s*′, and the focal length of a mirror are related according to $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$, where $f = \frac{1}{2}r$ and *r* is the radius of curvature of the mirror. In this problem, $f = -12$ cm because *r* is negative for a convex mirror.

(*a*) Solve the mirror equation for *s*′:

$$s' = \frac{fs}{s-f}$$

When *s* = 55 cm:

$$s' = \frac{(-12\,\text{cm})(55\,\text{cm})}{55\,\text{cm}-(-12\,\text{cm})} = -9.85\,\text{cm} = \boxed{-9.9\,\text{cm}}$$

When *s* = 24 cm:

$$s' = \frac{(-12\,\text{cm})(24\,\text{cm})}{24\,\text{cm}-(-12\,\text{cm})} = \boxed{-8.0\,\text{cm}}$$

When *s* = 12 cm:

$$s' = \frac{(-12\,\text{cm})(12\,\text{cm})}{12\,\text{cm}-(-12\,\text{cm})} = \boxed{-6.0\,\text{cm}}$$

When *s* = 8.0 cm:

$$s' = \frac{(-12\,\text{cm})(8.0\,\text{cm})}{8.0\,\text{cm}-(-12\,\text{cm})} = \boxed{-4.8\,\text{cm}}$$

(*b*) The lateral magnification is given by:

$$m = -\frac{s'}{s}$$

When *s* = 55 cm, the lateral magnification of the image is:

$$m = -\frac{-9.85\,\text{cm}}{55\,\text{cm}} = \boxed{0.18}$$

When *s* = 24 cm, the lateral magnification of the image is:

$$m = -\frac{-8.0\,\text{cm}}{24\,\text{cm}} = \boxed{0.33}$$

When *s* = 12 cm, the lateral magnification of the image is:

$$m = -\frac{-6.0\,\text{cm}}{12\,\text{cm}} = \boxed{0.50}$$

When s = 8.0 cm, the lateral magnification of the image is:

$$m = -\frac{-4.80\,\text{cm}}{8.0\,\text{cm}} = \boxed{0.60}$$

Remarks: These results are in excellent agreement with those obtained graphically in Problem 26.

28 •• Use the mirror equation (Equation 32-4 where $f = r/2$) to prove that a convex mirror cannot form a real image of a real object, no matter where the object is placed.

Picture the Problem We can solve the mirror equation for $1/s'$ and then examine the implications of $f < 0$ and $s > 0$.

Solve the mirror equation for $1/s'$:

$$\frac{1}{s'} = \frac{1}{f} - \frac{1}{s} = \frac{s-f}{sf}$$

For a convex mirror:

$$f < 0$$

For $s > 0$, the numerator is positive and the denominator negative. Consequently:

$$\frac{1}{s'} < 0 \Rightarrow \boxed{s' < 0}$$

29 • **[SSM]** A dentist wants a small mirror that will produce an upright image that has a magnification of 5.5 when the mirror is located 2.1 cm from a tooth. (*a*) Should the mirror be concave or convex? (*b*) What should the radius of curvature of the mirror be?

Picture the Problem We can use the mirror equation and the definition of the lateral magnification to find the radius of curvature of the dentist's mirror.

(*a*) The mirror must be concave. A convex mirror always produces a diminished virtual image.

(*b*) Express the mirror equation:

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} = \frac{2}{r} \Rightarrow r = \frac{2ss'}{s'+s} \qquad (1)$$

The lateral magnification of the mirror is given by:

$$m = -\frac{s'}{s} \Rightarrow s' = -ms$$

Substitute for s' in equation (1) to obtain:

$$r = \frac{-2ms}{1-m}$$

Substitute numerical values and evaluate r:

$$r = \frac{-2(5.5)(2.1\,\text{cm})}{1-5.5} = \boxed{5.1\,\text{cm}}$$

30 •• Convex mirrors are used in many stores to provide a wide angle of surveillance for a reasonable mirror size. Your summer job is at a local convenience store that uses the mirror shown in Figure 32-58. This setup allows you (or the clerk) to survey the entire store when you are 5.0 m from the mirror. The mirror has a radius of curvature equal to 1.2 m. Assume all rays are paraxial. (*a*) If a customer is 10 m from the mirror, how far from the mirror is his image? (*b*) Is the image in front of or behind the mirror? (*c*) If the customer is 2.0 m tall, how tall is his image?

Picture the Problem We can use the mirror equation and the relationship between the focal length of a mirror and its radius of curvature to find the location of the image. We can then use the definition of the lateral magnification of the mirror to find the height of the image formed in the mirror.

(*a*) Solve the mirror equation for s':

$$s' = \frac{fs}{s-f} \text{ where } f = \tfrac{1}{2}r$$

Substitute for f and simplify to obtain:

$$s' = \frac{\frac{1}{2}rs}{s-\frac{1}{2}r} = \frac{rs}{2s-r}$$

Substitute numerical values and evaluate s':

$$s' = \frac{(-1.2\,\text{m})(10\,\text{m})}{2(10\,\text{m})-(-1.2\,\text{m})} = -56.6\,\text{cm}$$

and

$$\boxed{\text{the image is 57 cm from the mirror.}}$$

(*b*) Because the image distance is negative:

$$\boxed{\text{the image is behind the mirror.}}$$

(*c*) The lateral magnification of the mirror is given by Equation 32-5:

$$m = \frac{y'}{y} = -\frac{s'}{s} \Rightarrow y' = -\frac{s'}{s}y$$

Substitute numerical values and evaluate y':

$$y' = -\frac{-0.566\,\text{m}}{10\,\text{m}}(2.0\,\text{m}) = \boxed{11\,\text{cm}}$$

31 •• A certain telescope uses a concave spherical mirror that has a radius equal to 8.0 m. Find the location and diameter of the image of the moon formed by this mirror. The moon has a diameter of 3.5×10^6 m and is 3.8×10^8 m from Earth.

Picture the Problem We can use the mirror equation to locate the image formed in this mirror and the expression for the lateral magnification of the mirror to find the diameter of the image.

Solve the mirror equation for the location of the image of the moon:

$$s' = \frac{fs}{s - f}$$

Because $f = \frac{1}{2}r$:

$$s' = \frac{\frac{1}{2}rs}{s - \frac{1}{2}r} = \frac{rs}{2s - r}$$

Substitute numerical values and evaluate s':

$$s' = \frac{(8.0\,\text{m})(3.8\times10^{8}\,\text{m})}{2(3.8\times10^{8}\,\text{m}) - 8.0\,\text{m}} = \boxed{4.0\,\text{m}}$$

Express the lateral magnification of the mirror:

$$m = \frac{y'}{y} = -\frac{s'}{s} \Rightarrow y' = -\frac{s'}{s}y$$

Substitute numerical values and evaluate y':

$$y' = -\frac{4.0\,\text{m}}{3.8\times10^{8}\,\text{m}}(3.5\times10^{6}\,\text{m})$$
$$= -3.7\,\text{cm}$$

The 3.7-cm-diameter image is 4.0 m in front of the mirror.

32 •• A piece of a thin spherical shell that has a radius of curvature of 100 cm is silvered on both sides. The concave side of the piece forms a real image 75 cm from the piece. The piece is then turned around so that its convex side faces the object. The piece is moved so that the image is now 35 cm from the piece on the concave side. (*a*) How far was the piece moved? (*b*) Was it moved toward the object or away from the object?

Picture the Problem We can use the mirror equation to find the focal length of the piece of the thin spherical shell and then apply it a second time to find the object position after the piece has been moved.

(*a*) Solve the mirror equation for *f* to obtain:

$$f = \frac{ss'}{s' + s}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{(100\,\text{cm})(75\,\text{cm})}{75\,\text{cm} + 100\,\text{cm}} = 42.86\,\text{cm}$$

Solving the mirror equation for s yields:

$$s=\frac{fs'}{s'-f}$$

With the piece turned around, $f=-42.86$ cm and $s'=-35$ cm. Substitute numerical values and evaluate s:

$$s=\frac{(-42.86\,\text{cm})(-35\,\text{cm})}{-35\,\text{cm}-(-42.86\,\text{cm})}\approx 191\,\text{cm}$$

The distance d the mirror moved is:

$$d=191\,\text{cm}-100\,\text{cm}=\boxed{91\,\text{cm}}$$

(b) The piece was moved *away from* the object.

33 •• Two light rays parallel to the optic axis of a concave mirror strike that mirror as shown in Figure 32-59. This mirror has a radius of curvature equal to 5.0 m. They then strike a small spherical mirror that is 2.0 m from the large mirror. The light rays finally meet at the vertex of the large mirror. Note: The small mirror is shown as planar, so as not to give away the answer, but it is *not* actually planar. (a) What is the radius of curvature of the small mirror? (b) Is that mirror convex or concave? Explain your answer.

Picture the Problem Denote the larger mirror on the right using the numeral 1, the smaller mirror using the numeral 2, and the distance between the mirrors by d. Applying the mirror equation to the two mirrors will lead us to an expression for the radius of curvature of the small mirror.

(a) Apply the mirror equation to mirror 1:

$$\frac{1}{s_1}+\frac{1}{s_1'}=\frac{2}{r_1}$$

Because $s_1=\infty$:

$$\frac{1}{s_1'}=\frac{2}{r_1}\Rightarrow s_1'=\tfrac{1}{2}r_1$$

The image formed by mirror #1 serves as a virtual object for mirror 2. Apply the mirror equation to mirror 2 to obtain:

$$\frac{1}{s_2}+\frac{1}{s_2'}=\frac{2}{r_2}$$

or, because $s_2=d-s'_1=d-\tfrac{1}{2}r_1$,

$$\frac{1}{d-\tfrac{1}{2}r_1}+\frac{1}{s_2'}=\frac{2}{r_2}$$

Because the image distance for mirror 2 is d:

$$\frac{2}{2d-r_1}+\frac{1}{d}=\frac{2}{r_2}$$

Substituting numerical values yields:

$$\frac{2}{2(2.0\text{ m})-5.0\text{ m}}+\frac{1}{2.0\text{ m}}=\frac{2}{r_2}$$

Finally, solve for r_2 to obtain:

$$r_2=\boxed{-1.3\text{ m}}$$

(*b*) Because $f_2=\frac{1}{2}r_2<0$, the small mirror is $\boxed{\text{convex}}$.

Images Formed by Refraction

34 •• A very long 1.75-cm-diameter glass rod has one end ground and polished to a convex spherical surface that has a 7.20-cm radius. The glass material has an index of refraction of 1.68. (*a*) A point object in air is on the axis of the rod and 30.0 cm from the spherical surface. Find the location of the image and state whether the image is real or virtual. (*b*) Repeat Part (*a*) for a point object in air, on the axis, and 5.00 cm from the spherical surface. Draw a ray diagram for each case.

Picture the Problem We can use the equation for refraction at a single surface to find the images corresponding to these three object positions. The signs of the image distances will tell us whether the images are real or virtual and the ray diagrams will confirm the correctness of our analytical solutions.

Use the equation for refraction at a single surface to relate the image and object distances:

$$\frac{n_1}{s}+\frac{n_2}{s'}=\frac{n_2-n_1}{r} \quad (1)$$

Solving for s' yields:

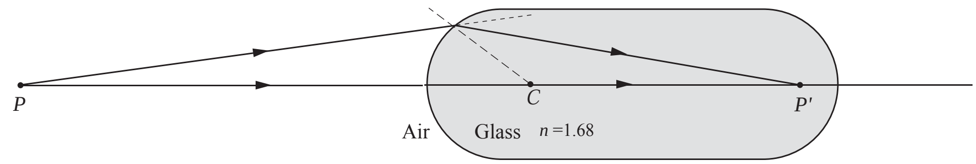
$$s'=\frac{n_2}{\frac{n_2-n_1}{r}-\frac{n_1}{s}}$$

(*a*) Substitute numerical values (s = 30.0 cm, n_1 = 1.00, n_2 = 1.68 and r = 7.20 cm) and evaluate s':

$$s'=\frac{1.68}{\frac{1.68-1.00}{7.20}-\frac{1.00}{30.0}}=\boxed{27\text{ cm}}$$

where the positive distance tells us that the image is 27 cm in back of the surface and is $\boxed{\text{real.}}$

In the following ray diagram, the object is at P and the image at P'.

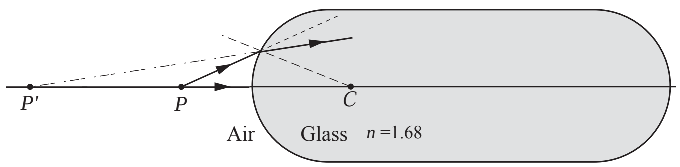


(*b*) Substitute numerical values (s = 5.00 cm, n_1 = 1.00, n_2 = 1.68 and r = 7.20 cm) and evaluate s':

$$s' = \frac{1.68}{\frac{1.68-1.00}{7.20} - \frac{1.00}{5.00}} = \boxed{-16\text{ cm}}$$

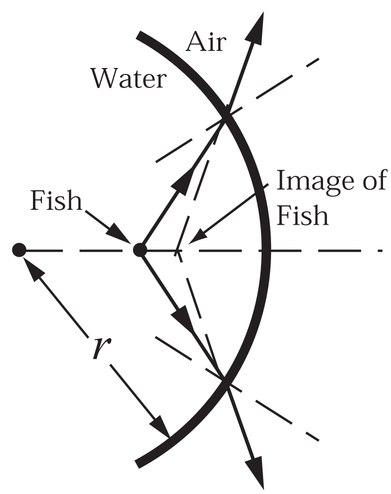
where the minus sign tells us that the image is 16 cm in front of the surface and is $\boxed{\text{virtual.}}$

In the following ray diagram, the object is at P and the image at P'.



35 • **[SSM]** A fish is 10 cm from the front surface of a spherical fish bowl of radius 20 cm. (*a*) How far behind the surface of the bowl does the fish appear to someone viewing the fish from in front of the bowl? (*b*) By what distance does the fish's apparent location change (relative to the front surface of the bowl) when it swims away to 30 cm from the front surface?

Picture the Problem The diagram shows two rays (from the bundle of rays) of light refracted at the water-air interface. Because the index of refraction of air is less than that of water, the rays are bent away from the normal. The fish will, therefore, appear to be closer than it actually is. We can use the equation for refraction at a single surface to find the distance s'. We'll assume that the glass bowl is thin enough that we can ignore the refraction of the light passing through it.



(*a*) Use the equation for refraction at a single surface to relate the image and object distances:

$$\frac{n_1}{s}+\frac{n_2}{s'}=\frac{n_2-n_1}{r}$$

Solving for s' yields:

$$s'=\frac{n_2}{\dfrac{n_2-n_1}{r}-\dfrac{n_1}{s}}$$

Substitute numerical values ($s = -10$ cm, $n_1 = 1.33$, $n_2 = 1.00$ and $r = 20$ cm) and evaluate s':

$$s'=\frac{1.00}{\dfrac{1.00-1.33}{20\text{ cm}}-\dfrac{1.33}{-10\text{ cm}}}=\boxed{8.6\text{ cm}}$$

and the image is 8.6 cm from the front surface of the bowl.

(*b*) For $s = 30$ cm:

$$s'=\frac{1.00}{\dfrac{1.00-1.33}{20\text{ cm}}-\dfrac{1.33}{-30\text{ cm}}}=35.9\text{ cm}$$

The change in the fish's apparent location is:

$$35.9\text{ cm}-8.6\text{ cm}\approx\boxed{27\text{ cm}}$$

36 •• A very long 1.75-cm-diameter glass rod has one end ground and polished to a concave spherical surface that has a 7.20-cm radius. The glass material has an index of refraction of 1.68. A point object in air is on the axis of the rod and 15.0 cm from the spherical surface. Find the location of the image and state whether the image is real or virtual. Draw a ray diagram.

Picture the Problem We can use the equation for refraction at a single surface to find the images corresponding to these three object positions. The signs of the image distances will tell us whether the images are real or virtual and the ray diagrams will confirm the correctness of our analytical solutions.

Use the equation for refraction at a single surface to relate the image and object distances:

$$\frac{n_1}{s}+\frac{n_2}{s'}=\frac{n_2-n_1}{r} \qquad (1)$$

Solving for s' yields:

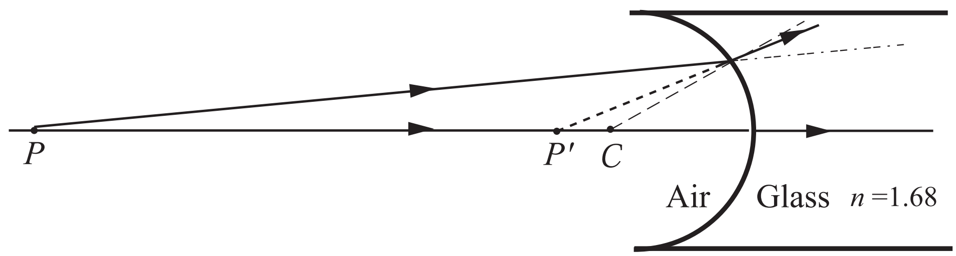
$$s'=\frac{n_2}{\dfrac{n_2-n_1}{r}-\dfrac{n_1}{s}}$$

Substitute numerical values (s = 15.0 cm, n_1 = 1.00, n_2 = 1.68, and r = −7.20 cm) and evaluate s':

$$s' = \frac{1.68}{\dfrac{1.68-1.00}{-7.20\text{ cm}} - \dfrac{1.00}{15.0\text{ cm}}} = \boxed{-10}$$

where the minus sign tells us that the image is 10 cm in front of the surface of the rod and is $\boxed{\text{virtual.}}$

In the following ray diagram, the object is at P and the virtual image is at P'.



37 •• [SSM] Repeat Problem 34 for when the glass rod and the object are immersed in water and (*a*) the object is 6.00 cm from the spherical surface, and (*b*) the object is 12.0 cm from the spherical surface.

Picture the Problem We can use the equation for refraction at a single surface to find the images corresponding to these three object positions. The signs of the image distances will tell us whether the images are real or virtual and the ray diagrams will confirm the correctness of our analytical solutions.

Use the equation for refraction at a single surface to relate the image and object distances:

$$\frac{n_1}{s} + \frac{n_2}{s'} = \frac{n_2 - n_1}{r} \qquad (1)$$

Solving for s' yields:

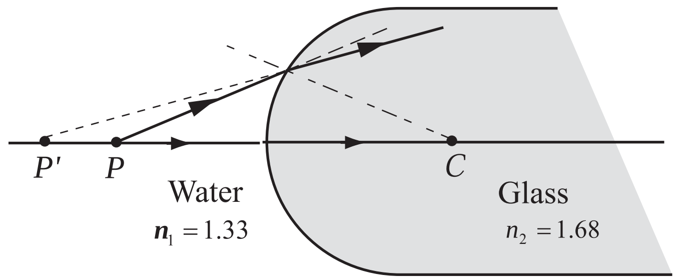
$$s' = \frac{n_2}{\dfrac{n_2 - n_1}{r} - \dfrac{n_1}{s}}$$

(*a*) Substitute numerical values (s = 6.00 cm, n_1 = 1.33, n_2 = 1.68, and r = 7.20 cm) and evaluate s':

$$s' = \frac{1.68}{\dfrac{1.68-1.33}{7.20\text{ cm}} - \dfrac{1.33}{6.00\text{ cm}}} = \boxed{-9.7\text{ cm}}$$

where the negative distance tells us that the image is 9.7 cm in front of the surface and is virtual.

In the following ray diagram, the object is at P and the virtual image is at P'.

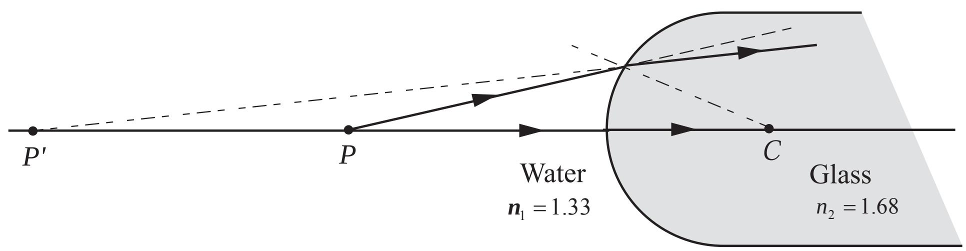


(*b*) Substitute numerical values (s = 12.0 cm, n_1 = 1.33, n_2 = 1.68, and r = 7.20 cm) and evaluate s':

$$s' = \frac{1.68}{\frac{1.68-1.33}{7.20\,\text{cm}} - \frac{1.33}{12.0\,\text{cm}}} = \boxed{-27\,\text{cm}}$$

where the negative distance tells us that the image is 27 cm in front of the surface and is virtual.

In the following ray diagram, the object is at P and the virtual image is at P'.



38 •• Repeat Problem 36 for when the glass rod and the object are immersed in water and the object is 20 cm from the spherical surface.

Picture the Problem We can use the equation for refraction at a single surface to find the images corresponding to these three object positions. The signs of the image distances will tell us whether the images are real or virtual and the ray diagrams will confirm the correctness of our analytical solutions.

Use the equation for refraction at a single surface to relate the image and object distances:

$$\frac{n_1}{s} + \frac{n_2}{s'} = \frac{n_2 - n_1}{r} \qquad (1)$$

Solving for s' yields:

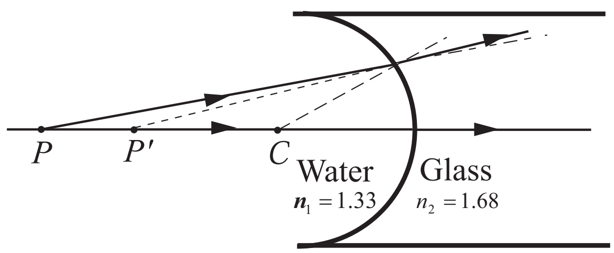
$$s' = \frac{n_2}{\frac{n_2 - n_1}{r} - \frac{n_1}{s}}$$

Substitute numerical values (s = 20 cm, n_1 = 1.33, n_2 = 1.68, and r = −7.20 cm) and evaluate s':

$$s' = \frac{1.68}{\frac{1.68 - 1.33}{-7.20\text{ cm}} - \frac{1.33}{20\text{ cm}}} = \boxed{-15}$$

where the minus sign tells us that the image is 15 cm in front of the surface of the rod and is virtual

In the following ray diagram the object is at P and the virtual image is at P'.



39 •• A rod that is 96.0-cm long is made of glass that has an index of refraction equal to 1.60. The rod has its ends ground to convex spherical surfaces that have radii equal to 8.00 cm and 16.0 cm. An object is in air on the long axis of the rod 20.0 cm from the end that has the 8.00-cm radius. (*a*) Find the image distance due to refraction at the 8.00-cm-radius surface. (*b*) Find the position of the final image due to refraction at both surfaces. (*c*) Is the final image real or virtual?

Picture the Problem (*a*) We can use the equation for refraction at a single surface to find the images due to refraction at the ends of the glass rod. (*b*) The image formed by the refraction at the first surface will serve as the object for the second surface. (*c*) The sign of the final image distance will tell us whether the image is real or virtual.

(*a*) Use the equation for refraction at a single surface to relate the image and object distances at the surface whose radius is 8.00 cm:

$$\frac{n_1}{s} + \frac{n_2}{s'} = \frac{n_2 - n_1}{r}$$

Solving for s' yields:

$$s' = \frac{n_2}{\frac{n_2 - n_1}{r} - \frac{n_1}{s}}$$

Substitute numerical values (s = 20.0 cm, n_1 = 1.00, n_2 = 1.60, and r = 8.00 cm) and evaluate s':

$$s' = \frac{1.60}{\frac{1.60-1.00}{8.00\text{ cm}} - \frac{1.00}{20.0\text{ cm}}} = \boxed{64\text{ cm}}$$

(b) The object for the second surface is 96 cm − 64 cm = 32 cm from the surface whose radius is −16.0 cm. Substitute numerical values (note that now n_1 = 1.60 and n_2 = 1.00) and evaluate s':

$$s' = \frac{1.00}{\frac{1.00-1.60}{-16.0\text{ cm}} - \frac{1.60}{32\text{ cm}}} = \boxed{-80\text{ cm}}$$

(c) The final image is inside the rod and 96 cm − 80 cm = 16 cm from the surface whose radius of curvature is 8.00 cm and is virtual.

40 •• Repeat Problem 39 for an object in air on the axis of the glass rod 20.0 cm from the end that has the 16.0-cm radius.

Picture the Problem (a) We can use the equation for refraction at a single surface to find the images due to refraction at the ends of the glass rod. (b) The image formed by the refraction at the first surface will serve as the object for the second surface. (c) The sign of the final image distance will tell us whether the image is real or virtual.

(a) Use the equation for refraction at a single surface to relate the image and object distances at the surface that has a 16.0 cm radius:

$$\frac{n_1}{s} + \frac{n_2}{s'} = \frac{n_2 - n_1}{r}$$

Solving for s' yields:

$$s' = \frac{n_2}{\frac{n_2-n_1}{r} - \frac{n_1}{s}}$$

Substitute numerical values (s = 20.0 cm, n_1 = 1.00, n_2 = 1.60 and r = 16.0 cm) evaluate s':

$$s' = \frac{1.60}{\frac{1.60-1.00}{16.0\text{ cm}} - \frac{1.00}{20.0\text{ cm}}} = -128\text{ cm} = \boxed{-1.3\times10^{2}\text{ cm}}$$

where the minus sign tells us that the image is 1.3×10^2 cm to the left of the surface whose radius of curvature is 16.0 cm.

(*b*) The object for the second surface is 96 cm + 128 cm = 224 cm from the surface whose radius of curvature is −8.00 cm. Substitute numerical values (note that now n_1 = 1.60 and n_2 = 1.00) and evaluate s':

$$s' = \frac{1.00}{\frac{1.00-1.60}{-8.00\text{ cm}} - \frac{1.60}{224\text{ cm}}} = 14.7\text{ cm}$$

$$= \boxed{15\text{ cm}}$$

(*c*) The final image is outside the rod, 15 cm from the end whose radius of curvature is 8.00 cm, and is real.

Thin Lenses

41 • [SSM] A double concave lens that has an index of refraction equal to 1.45 has radii whose magnitudes are equal to 30.0 cm and 25.0 cm. An object is located 80.0 cm to the left of the lens. Find (*a*) the focal length of the lens, (*b*) the location of the image, and (*c*) the magnification of the image. (*d*) Is the image real or virtual? Is the image upright or inverted?

Picture the Problem We can use the lens-maker's equation to find the focal length of the lens and the thin-lens equation to locate the image. We can use $m = -\frac{s'}{s}$ to find the lateral magnification of the image.

(*a*) The lens-maker's equation is:

$$\frac{1}{f} = \left(\frac{n}{n_{\text{air}}} - 1\right)\left(\frac{1}{r_1} - \frac{1}{r_2}\right)$$

where the numerals 1 and 2 denote the first and second surfaces, respectively.

Substitute numerical values to obtain:

$$\frac{1}{f} = \left(\frac{1.45}{1.00} - 1\right)\left(\frac{1}{-30.0\text{ cm}} - \frac{1}{25.0\text{ cm}}\right)$$

Solving for f yields:

$$f = -30.3\text{ cm} = \boxed{-30\text{ cm}}$$

(*b*) Use the thin-lens equation to relate the image and object distances:

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} \Rightarrow s' = \frac{fs}{s-f}$$

Substitute numerical values and evaluate s':

$$s' = \frac{(-30.3\,\text{cm})(80.0\,\text{cm})}{80.0\,\text{cm} - (-30.3\,\text{cm})} = -21.98\,\text{cm}$$
$$= -22\,\text{cm}$$

The image is 22 cm from the lens and on the same side of the lens as the object.

(*c*) The lateral magnification of the image is given by:

$$m = -\frac{s'}{s}$$

Substitute numerical values and evaluate m:

$$m = -\frac{-21.98\,\text{cm}}{80.0\,\text{cm}} = \boxed{0.27}$$

(*d*) Because $s' < 0$ and $m > 0$, the image is $\boxed{\text{virtual and upright.}}$

42 • The following thin lenses are made of glass that has an index of refraction equal to 1.60. Make a sketch of each lens and find each focal length in air: (*a*) r_1 = 20.0 cm and r_2 = 10.0 cm, (*b*) r_1 = 10.0 cm and r_2 = 20.0 cm, and (*c*) r_1 = –10.0 cm and r_2 = –20.0 cm.

Picture the Problem We can use the lens-maker's equation to find the focal length of each of the lenses described in the problem statement.

The lens-maker's equation is:

$$\frac{1}{f} = \left(\frac{n}{n_{\text{air}}} - 1\right)\left(\frac{1}{r_1} - \frac{1}{r_2}\right)$$

where the numerals 1 and 2 denote the first and second surfaces, respectively.

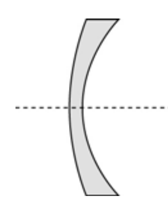
(*a*) For r_1 = 20.0 cm and r_2 = 10.0 cm:

$$\frac{1}{f} = \left(\frac{1.60}{1.00} - 1\right)\left(\frac{1}{20.0\,\text{cm}} - \frac{1}{10.0\,\text{cm}}\right)$$

and

$$f = \boxed{-33\,\text{cm}}$$

A sketch of the lens is shown to the right:



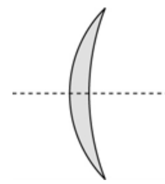
(*b*) For r_1 = 10.0 cm and r_2 = 20.0 cm:

$$\frac{1}{f}=\left(\frac{1.60}{1.00}-1\right)\left(\frac{1}{10.0\,\text{cm}}-\frac{1}{20.0\,\text{cm}}\right)$$

and

$$f=\boxed{33\,\text{cm}}$$

A sketch of the lens is shown to the right:

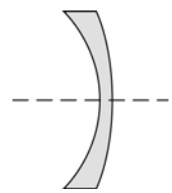


(*c*) For r_1 = –10.0 cm and r_2 = –20.0 cm:

$$\frac{1}{f}=\left(\frac{1.60}{1.00}-1\right)\left(\frac{1}{-10.0\,\text{cm}}-\frac{1}{-20.0\,\text{cm}}\right)$$

and $f=\boxed{-33\,\text{cm}}$

A sketch of the lens is shown to the right:



Remarks: Note that the lenses that are thicker on their axis than on their circumferences are positive (converging) lenses and those that are thinner on their axis are negative (diverging) lenses.

43 • The following four thin lenses are made of glass that has an index of refraction of 1.5. The radii given are *magnitudes*. Make a sketch of each lens and find each focal length in air: (*a*) double-convex that has radii of curvature equal to 15 cm and 26 cm, (*b*) plano-convex that has a radius of curvature equal to 15 cm, (*c*) double concave that has radii of curvature equal to 15 cm, and (*d*) plano-concave that has a radius of curvature equal to 26 cm.

Picture the Problem We can use the lens-maker's equation to find the focal length of each of the lenses.

The lens-maker's equation is:

$$\frac{1}{f}=\left(\frac{n}{n_{\text{air}}}-1\right)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

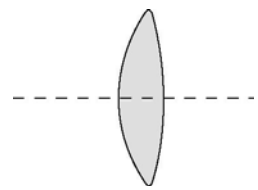
where the numerals 1 and 2 denote the first and second surfaces, respectively.

(*a*) Because the lens is double convex, the radius of curvature of the second surface is negative. Hence $r_1 = 15$ cm and $r_2 = -26$ cm:

$$\frac{1}{f} = \left(\frac{1.50}{1.00} - 1\right)\left(\frac{1}{15\,\text{cm}} - \frac{1}{-26\,\text{cm}}\right)$$

and $f = \boxed{19\,\text{cm}}$

A double convex lens is shown to the right:

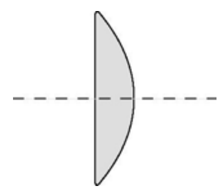


(*b*) Because the lens is plano-convex, the radius of curvature of the second surface is negative. Hence $r_1 = \infty$ and $r_2 = -15$ cm:

$$\frac{1}{f} = \left(\frac{1.50}{1.00} - 1\right)\left(\frac{1}{\infty} - \frac{1}{-15\,\text{cm}}\right)$$

and $f = \boxed{30\,\text{cm}}$

A plano-convex lens is shown to the right:

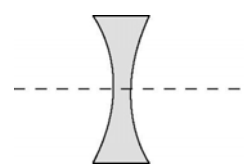


(*c*) Because the lens is double concave, the radius of curvature of its first surface is negative. Hence $r_1 = -15$ cm and $r_2 = +15$ cm:

$$\frac{1}{f} = \left(\frac{1.50}{1.00} - 1\right)\left(\frac{1}{-15\,\text{cm}} - \frac{1}{15\,\text{cm}}\right)$$

and $f = \boxed{-15\,\text{cm}}$

A double concave lens is shown to the right:

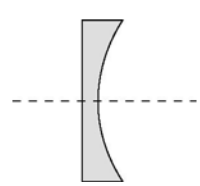


(*d*) Because the lens is plano-concave, the radius of curvature of its second surface is positive. Hence $r_1 = \infty$ and $r_2 = +26$ cm:

$$\frac{1}{f} = \left(\frac{1.50}{1.00} - 1\right)\left(\frac{1}{\infty} - \frac{1}{26\,\text{cm}}\right)$$

and $f = \boxed{-52\,\text{cm}}$

A plano-concave lens is shown to the right:



44 • Find the focal length of a glass lens that has an index of refraction equal to 1.62, a concave surface that has a radius of curvature of magnitude 100 cm, and a convex surface that has a radius of curvature of magnitude 40.0 cm.

Picture the Problem We can use the lens-maker's equation to find the focal length of the lens.

The lens-maker's equation is:

$$\frac{1}{f}=\left(\frac{n}{n_{\text{air}}}-1\right)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

where the numerals 1 and 2 denote the first and second surfaces, respectively.

Substitute numerical values to obtain:

$$\frac{1}{f}=\left(\frac{1.62}{1.00}-1\right)\left(\frac{1}{-100\,\text{cm}}-\frac{1}{-40.0\,\text{cm}}\right)$$

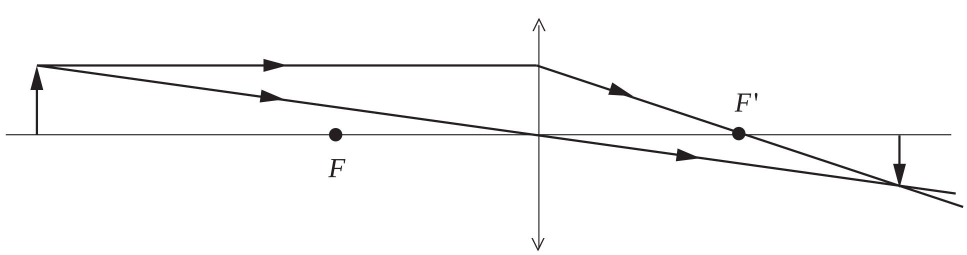
Solving for f yields:

$$f=\boxed{1.1\ \text{m}}$$

45 •• **[SSM]** (*a*) An object that is 3.00 cm high is placed 25.0 cm in front of a thin lens that has a power equal to 10.0 D. Draw a ray diagram to find the position and the size of the image and check your results using the thin-lens equation. (*b*) Repeat Part (*a*) if the object is placed 20.0 cm in front of the lens. (*c*) Repeat Part (*a*) for an object placed 20.0 cm in front of a thin lens that has a power equal to –10.0 D.

Picture the Problem We can find the focal length of each lens from the definition of the power *P*, in diopters, of a lens ($P = 1/f$). The thin-lens equation can be applied to find the image distance for each lens and the size of the image can be found from the magnification equation $m=\frac{y'}{y}=-\frac{s'}{s}$.

(*a*) The parallel and central rays were used to locate the image in the diagram shown below.



The image is real, inverted, and diminished.

Solving the thin-lens equation for s' yields:

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow s'=\frac{fs}{s-f} \qquad (1)$$

Use the definition of the power of the lens to find its focal length:

$$f=\frac{1}{P}=\frac{1}{10.0\,\text{m}^{-1}}=0.100\,\text{m}=10.0\,\text{cm}$$

Substitute numerical values and evaluate s':

$$s'=\frac{(10.0\,\text{cm})(25.0\,\text{cm})}{25.0\,\text{cm}-10.0\,\text{cm}}=16.7\,\text{cm}$$

Use the lateral magnification equation to relate the height of the image y' to the height y of the object and the image and object distances:

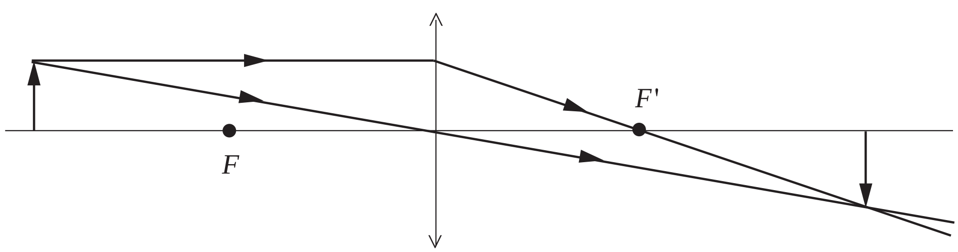
$$m=\frac{y'}{y}=-\frac{s'}{s}\Rightarrow y'=-\frac{s'}{s}y \qquad (2)$$

Substitute numerical values and evaluate y':

$$y'=-\frac{16.7\,\text{cm}}{25.0\,\text{cm}}(3.00\,\text{cm})=-2.00\,\text{cm}$$

$s'=16.7\,\text{cm}$, $y'=-2.00\,\text{cm}$. Because $s'>0$, the image is real, and because $y'/y=-0.67$ cm, the image is inverted and diminished. These results confirm those obtained graphically.

(*b*) The parallel and central rays were used to locate the image in the following diagram.



The image is real and inverted and appears to be the same size as the object.

Use the definition of the power of the lens to find its focal length:

$$f=\frac{1}{10.0\,\text{m}^{-1}}=0.100\,\text{m}=10.0\,\text{cm}$$

Substitute numerical values in equation (1) and evaluate s':

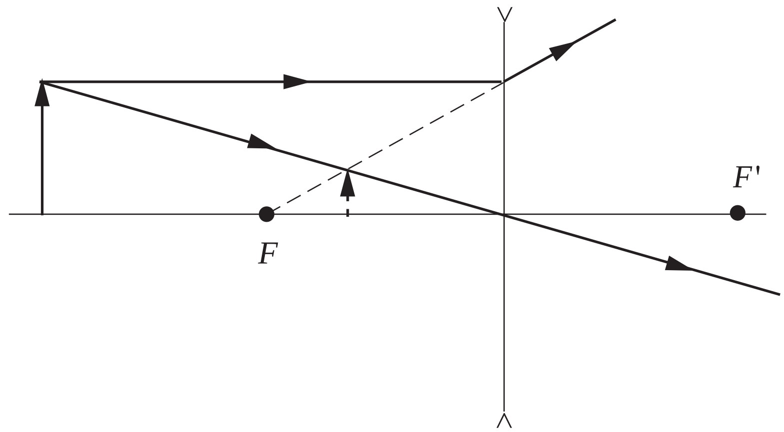
$$s'=\frac{(10.0\,\text{cm})(20.0\,\text{cm})}{20.0\,\text{cm}-10.0\,\text{cm}}=\boxed{20.0\,\text{cm}}$$

Substitute numerical values in equation (2) and evaluate y':

$$y'=-\frac{20.0\,\text{cm}}{20.0\,\text{cm}}(3.00\,\text{cm})=\boxed{-3.00\,\text{cm}}$$

Because $s' > 0$ and $y' = -3.00$ cm, the image is real, inverted, and the same size as the object. These results confirm those obtained from the ray diagram.

(*c*) The parallel and central rays were used to locate the image in the following diagram.



The image is virtual, upright, and diminished.

Use the definition of the power of the lens to find its focal length:

$$f = \frac{1}{-10.0\,\text{m}^{-1}} = -0.100\,\text{m} = -10.0\,\text{cm}$$

Substitute numerical values in equation (1) and evaluate s':

$$s' = \frac{(-10.0\,\text{cm})(20.0\,\text{cm})}{20.0\,\text{cm} - (-10.0\,\text{cm})} = \boxed{-6.67\,\text{cm}}$$

Substitute numerical values in equation (2) and evaluate y':

$$y' = -\frac{-6.67\,\text{cm}}{20.0\,\text{cm}}(3.00\,\text{cm}) = \boxed{1.00\,\text{cm}}$$

Because $s' < 0$ and $y' = 1.00$ cm, the image is virtual, erect, and about one-third the size of the object. These results are consistent with those obtained graphically.

46 •• The lens-maker's equation has three design parameters. They consist of the index of refraction of the lens and the radii of curvature for its two surfaces. Thus, there are many ways to design a lens that has a particular focal length in air. Use the lens-maker's equation to design three different thin converging lenses, each having a focal length of 27.0 cm and each made from glass that has an index of refraction of 1.60. Sketch each of your designs.

Picture the Problem We can use the lens-maker's equation to obtain a relationship between the two radii of curvature of the lenses we are to design.

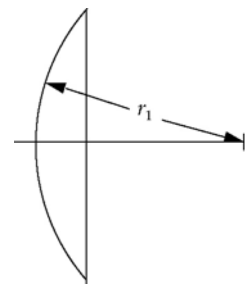
For a thin lens of focal length 27.0 cm and index of refraction of 1.60:

$$\frac{1}{27.0\,\text{cm}} = (1.60-1)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

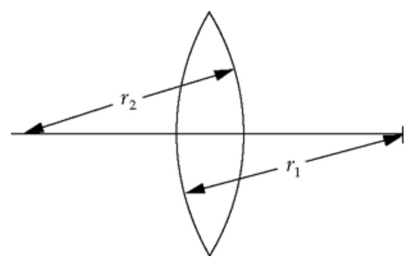
or

$$\frac{1}{r_1}-\frac{1}{r_2} = \frac{1}{16.2\,\text{cm}}$$

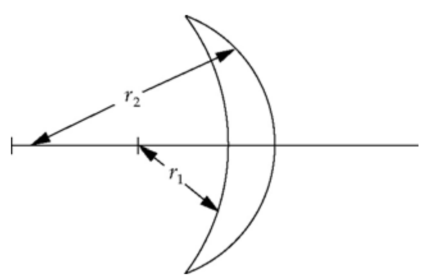
One solution is a plano-convex lens (one with a flat surface and a convex surface). Let $r_2 = \infty$. Then $r_1 = \boxed{16.2\,\text{cm}}$ and $r_2 = \boxed{\infty}$.



Another design is a double convex lens (one with both surfaces convex and radii of curvature that are equal in magnitude) obtained by letting $r_2 = -r_1$. Then $r_1 = \boxed{32.4\,\text{cm}}$ and $r_2 = \boxed{-32.4\,\text{cm}}$.



A third possibility is a double convex lens with unequal curvature, e.g., let $r_2 = -12.0$ cm. Then $r_1 = \boxed{-6.89\,\text{cm}}$ and $r_2 = \boxed{-12.0\,\text{cm}}$.



47 •• Repeat Problem 46, but for a diverging lens that has a focal length in air of the same magnitude.

Picture the Problem We can use the lens-maker's equation to obtain a relationship between the two radii of curvature of the lenses we are to design.

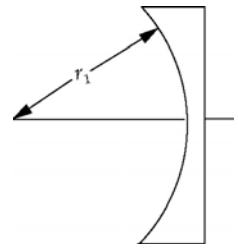
For a thin lens of focal length –27.0 cm and index of refraction of 1.60:

$$\frac{1}{-27.0\,\text{cm}} = (1.60-1)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

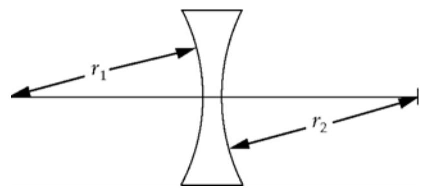
or

$$\frac{1}{r_1}-\frac{1}{r_2} = \frac{1}{-16.2\,\text{cm}}$$

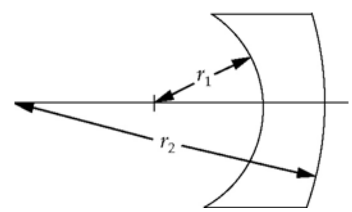
One solution is a plano-concave lens (one with a flat surface and a concave surface), Let $r_2 = \infty$. Then $r_1 = \boxed{-16.2\,\text{cm}}$ and $r_2 = \boxed{\infty}$.



Another design is a biconcave lens (one with both surfaces concave) by letting $r_2 = -r_1$. Then $r_1 = \boxed{-32.4\,\text{cm}}$ and $r_2 = \boxed{32.4\,\text{cm}}$.



A third possibility is a lens with $r_2 = -8.10$ cm.
Then $r_1 = \boxed{-5.40\,\text{cm}}$ and $r_2 = \boxed{-8.10\,\text{cm}}$.



48 •• (*a*) What is meant by a negative object distance? Describe a specific situation in which a negative object distance can occur. (*b*) Find the image distance and the magnification for a thin lens in air when the object distance is –20 cm and the lens is a converging lens that has a focal length of 20 cm. Describe the image—is it virtual or real, upright or inverted? (*c*) Repeat Part (*b*) if the object distance is, instead, –10 cm, and the lens is diverging and has a focal length (magnitude) of 30 cm.

Picture the Problem The parallel and central rays were used to locate the image in the diagram shown below. The power *P* of the lens, in diopters, can be found from $P = 1/f$ and the lateral magnification of the image from $m = -\frac{s'}{s}$.

(*a*) A negative object distance means that the object is virtual; i.e., that extensions of light rays, and not the light rays themselves, converge on the object rather than diverge from it. A virtual object can occur in a two-lens system when converging rays from the first lens are incident on the second lens before they converge to form an image.

(*b*) The thin-lens equation is:

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}\Rightarrow s'=\frac{fs}{s-f}$$

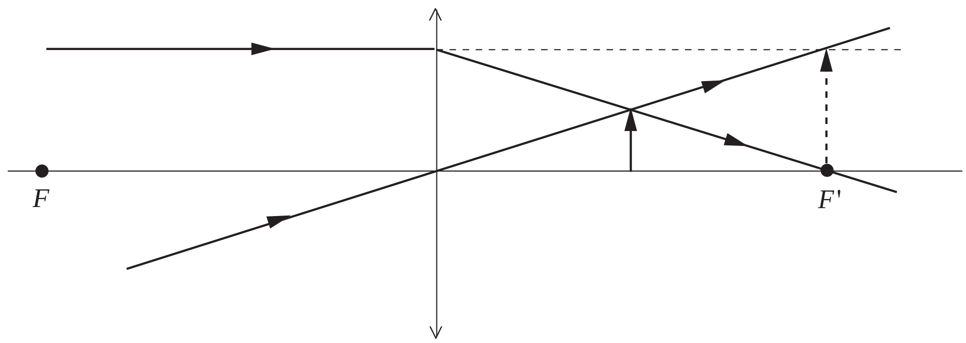
Substitute numerical values and evaluate s':

$$s' = \frac{(20\,\text{cm})(-20\,\text{cm})}{-20\,\text{cm}-(20\,\text{cm})} = 10\,\text{cm}$$

The lateral magnification is given by:

$$m = -\frac{s'}{s} = -\frac{10\text{ cm}}{-20\text{ cm}} = 0.50$$

The parallel and central rays were used to locate the image in the following ray diagram:



$s' = 10$ cm, $m = 0.50$. Because $s' > 0$, the image is real, and because $m > 0$, the image is erect. In addition, it is one-half the size of the virtual object.

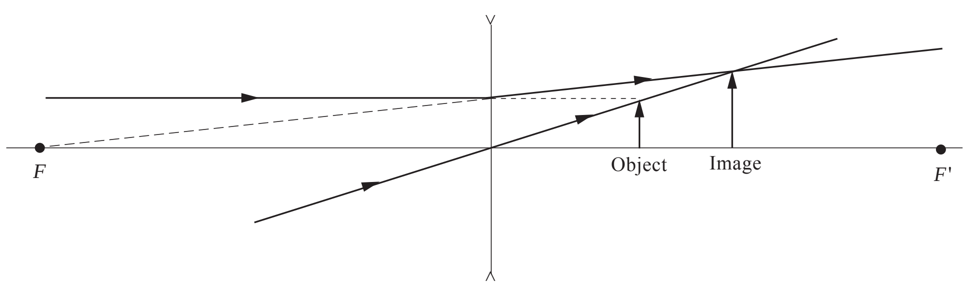
(*c*) Proceed as in Part (*b*) with $s = -10$ cm and $f = -30$ cm:

$$s' = \frac{(-30\,\text{cm})(-10\,\text{cm})}{-10\,\text{cm}-(-30\,\text{cm})} = 15\,\text{cm}$$

and

$$m = -\frac{s'}{s} = -\frac{15\,\text{cm}}{-10\,\text{cm}} = 1.5$$

The parallel and central rays were used to locate the image in the following ray diagram:

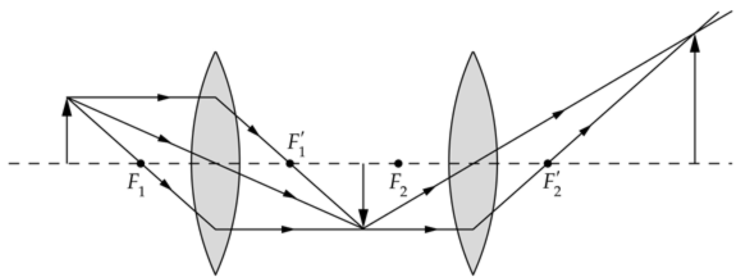


$s' > 0$ and $m = 1.5$. Because $s' > 0$, the image is real, and because $m > 0$, the image is erect. In addition, it is one and one-half times the size of the virtual object.

49 •• **[SSM]** Two converging lenses, each having a focal length equal to 10 cm, are separated by 35 cm. An object is 20 cm to the left of the first lens. (*a*) Find the position of the final image using both a ray diagram and the thin-lens equation. (*b*) Is the final image real or virtual? Is the final image upright or inverted? (*c*) What is the overall lateral magnification of the final image?

Picture the Problem We can apply the thin-lens equation to find the image formed in the first lens and then use this image as the object for the second lens.

(*a*) The parallel, central, and focal rays were used to locate the image formed by the first lens and the parallel and central rays to locate the image formed by the second lens.



Apply the thin-lens equation to express the location of the image formed by the first lens:

$$s_1' = \frac{f_1 s_1}{s_1 - f_1} \quad (1)$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(10\,\text{cm})(20\,\text{cm})}{20\,\text{cm} - 10\,\text{cm}} = 20\,\text{cm}$$

Find the lateral magnification of the first image:

$$m_1 = -\frac{s_1'}{s} = -\frac{20\,\text{cm}}{20\,\text{cm}} = -1.0$$

Because the lenses are separated by 35 cm, the object distance for the second lens is 35 cm – 20 cm = 15 cm. Equation (1) applied to the second lens is:

$$s_2' = \frac{f_2 s_2}{s_2 - f_2}$$

Substitute numerical values and evaluate s_2':

$$s_2' = \frac{(10\,\text{cm})(15\,\text{cm})}{15\,\text{cm} - 10\,\text{cm}} = 30\,\text{cm}$$

and the final image is $\boxed{85\,\text{cm}}$ to the right of the object.

Find the lateral magnification of the second image:

$$m_2 = -\frac{s_2'}{s} = -\frac{30\,\text{cm}}{15\,\text{cm}} = -2.0$$

(*b*) Because $s'_2 > 0$, the image is real and because $m = m_1 m_2 = 2.0$, the image is erect and twice the size of the object.

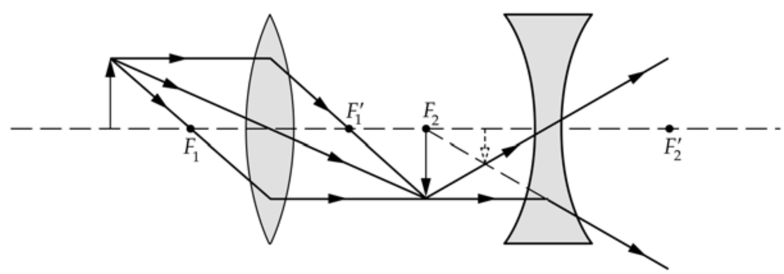
(*c*) The overall lateral magnification of the image is the product of the magnifications of each image:

$$m = m_1 m_2 = (-1.0)(-2.0) = \boxed{2.0}$$

50 •• Repeat Problem 49 but with the second lens replaced by a diverging lens that has a focal length equal to −15 cm.

Picture the Problem We can apply the thin-lens equation to find the image formed in the first lens and then use this image as the object for the second lens.

(*a*) The parallel, central, and focal rays were used to locate the image formed by the first lens and the parallel and central rays to locate the image formed by the second lens.



Apply the thin-lens equation to express the location of the image formed by the first lens:

$$s_1' = \frac{f_1 s_1}{s_1 - f_1} \quad (1)$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(10\,\text{cm})(20\,\text{cm})}{20\,\text{cm} - 10\,\text{cm}} = 20\,\text{cm}$$

Find the lateral magnification of the first image:

$$m_1 = -\frac{s'_1}{s} = -\frac{20\,\text{cm}}{20\,\text{cm}} = -1.0$$

Because the lenses are separated by 35 cm, the object distance for the second lens is 35 cm – 20 cm = 15 cm. Equation (1) applied to the second lens is:

$$s_2' = \frac{f_2 s_2}{s_2 - f_2}$$

Substitute numerical values and evaluate s_2':

$$s_2' = \frac{(-15\,\text{cm})(15\,\text{cm})}{15\,\text{cm} - (-15\,\text{cm})} = -7.5\,\text{cm}$$

and the final image is $\boxed{48\,\text{cm}}$ to the right of the object.

Find the lateral magnification of the second image:

$$m_2 = -\frac{s_2'}{s} = -\frac{-7.5\,\text{cm}}{15\,\text{cm}} = 0.50$$

(*b*) Because $s'_2 < 0$ and $m = m_1m_2 = -0.50$, the image is virtual, inverted, and half the height of the object.

(*c*) The overall lateral magnification of the image is the product of the magnifications of each image:

$$m = m_1 m_2 = (-1.0)(0.50) = \boxed{-0.50}$$

51 •• (*a*) Show that to obtain a magnification of magnitude $|m|$ using a converging thin lens of focal length *f*, the object distance must be equal to $\left(1 + |m|^{-1}\right)f$. (*b*) You want to use a digital camera which has a lens whose focal length is 50.0 mm to take a picture of a person 1.75 m tall. How far from the camera lens should you have that person stand so that the image size on the light receiving sensors of your camera is 24.0 mm?

Picture the Problem We can use the thin-lens equation and the definition of the lateral magnification to derive the result.

(*a*) Start with the thin-lens equation:

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$$

Express the magnitude of the lateral magnification of the image and solve for s': (Note that this ensures that s' is positive for this situation, as it must be because the image is real.)

$$|m| = \left|-\frac{s'}{s}\right| \Rightarrow s' = |m|s$$

Substitute for s' to obtain:

$$\frac{1}{s} + \frac{1}{|m|s} = \frac{1}{f} \Rightarrow s = \boxed{\left(1 + |m|^{-1}\right)f}$$

(*b*) The magnitude of the magnification *m* is:

$$m = \left|-\frac{y'}{y}\right| = \frac{24.0\,\text{mm}}{1.75\,\text{m}} = 0.0137$$

Substitute numerical values and evaluate s:

$$s=\frac{(0.0137+1)(50.0\,\text{mm})}{0.0137}=\boxed{3.70\,\text{m}}$$

52 •• A converging lens has a focal length of 12.0 cm. (*a*) Using a **spreadsheet** program or graphing calculator, plot the image distance as a function of the object distance, for object distances ranging from $1.10f$ to $10.0f$ where f is the focal length. (*b*) On the same graph used in Part (*a*), but using a different y axis, plot the magnification of the lens as a function of the object distance. (*c*) What type of image is produced for this range of object distances—real or virtual, upright or inverted? (*d*) Discuss the significance of any asymptotic limits your graphs have.

Picture the Problem We can plot the first graph by solving the thin-lens equation for the image distance s' and the second graph by using the definition of the magnification of the image.

(*a*) and (*b*) Solve the thin-lens equation for s' to obtain:

$$s'=\frac{fs}{s-f}$$

The magnification of the image is given by:

$$m=-\frac{s'}{s}$$

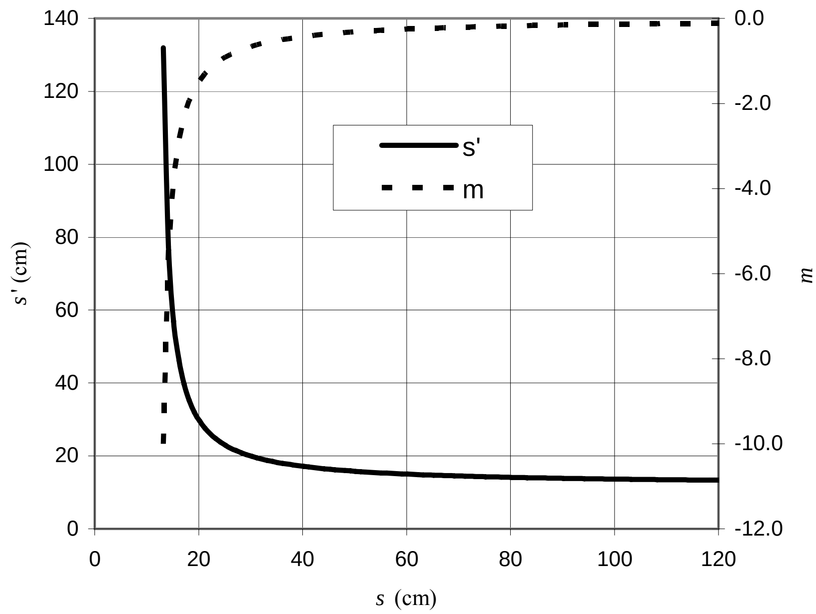
A spreadsheet program to calculate s' as a function of s is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
B1	12	f
A4	13.2	s
A5	A4 + 1	$s+\Delta s$
B4	$B$1*A4/(A4 – $B$1)	$\frac{fs}{s-f}$
C5	–B4/A4	$-\frac{s'}{s}$

	A	B	C
1	f=	12	cm
2			
3	s	s'	m
4	13.2	132.00	–10.00
5	14.2	77.45	–5.45
6	15.2	57.00	–3.75
7	16.2	46.29	–2.86
8	17.2	39.69	–2.31
9	18.2	35.23	–1.94

108	117.2	13.37	−0.11
109	118.2	13.36	−0.11
110	119.2	13.34	−0.11
111	120.2	13.33	−0.11

A graph of s' and m as functions of s follows.



(c) The images are real and inverted for this range of object distances.

(d) The equations for the horizontal and vertical asymptotes of the graph of s' versus s are $s' = f$ and $s = f$, respectively. These indicate that as the object moves away from the lens image distance the image moves toward the first focal point, and that as the object moves toward the second focal point the image distance becomes large without limit. The equations for the horizontal and vertical asymptotes of the graph of m versus s are $m = 0$ and $s = f$, respectively. These indicate that as the object moves away from the lens, the image size of the image approaches zero, and that as the object moves toward the second focal point the image becomes large without limit.

53 •• A converging lens has a focal length of 12.0 cm. (a) Using a **spreadsheet** program or graphing calculator, plot the image distance as a function of the object distance, for object distances ranging from $0.010f$ to $s = 0.90f$, where f is the focal length. (b) On the same graph used in Part (a), but using a different y axis, plot the magnification of the lens as a function of the object distance.
(c) What type of image is produced for this range of object distances—real or virtual, upright or inverted? (d) Discuss the significance of any asymptotic limits your graphs have.

Picture the Problem We can plot the first graph by solving the thin-lens equation for the image distance s' and the second graph by using the definition of the magnification of the image.

(*a*) and (*b*) Solve the thin-lens equation for s' to obtain:

$$s' = \frac{fs}{s-f}$$

The magnification of the image is given by:

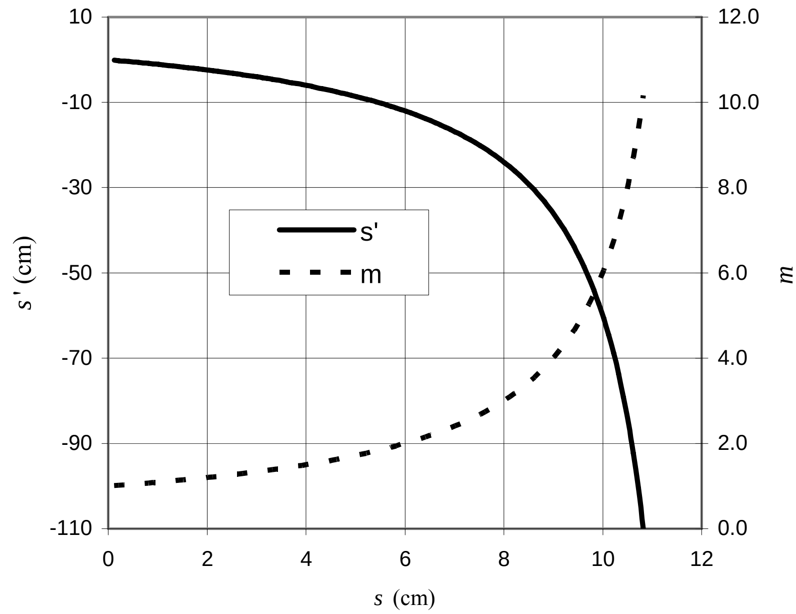
$$m = -\frac{s'}{s}$$

A spreadsheet program to calculate s' as a function of s is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
B1	12	f
A4	0.12	s
A5	A4 + 0.1	$s + \Delta s$
B4	$B$1*A4/(A4 – $B$1)	$\frac{fs}{s-f}$
C5	–B4/A4	$-\frac{s'}{s}$

	A	B	C
1	*f*=	12	cm
2			
3	*s*	*s'*	*m*
4	0.12	–0.12	1.01
5	0.22	–0.22	1.02
6	0.32	–0.33	1.03
7	0.42	–0.44	1.04
8	0.52	–0.54	1.05
9	0.62	–0.65	1.05
108	10.52	–85.30	8.11
109	10.62	–92.35	8.70
110	10.72	–100.50	9.37
111	10.82	–110.03	10.17

A graph of s' and m as functions of s follows.



(c) The images are virtual and erect for this range of object distances.

(d) The equation for the vertical asymptote of the graph of s' versus s is $f = s$. This indicates that, as the object moves toward the second focal point, the magnitude of the image distance becomes large without limit. The equation for the vertical asymptote of the graph of m versus s is $s = f$. This indicates that, as the object moves toward the second focal point, the image becomes large without limit. In addition, as s approaches zero, s' approaches negative infinity and m approaches 1, so as the object moves toward the lens the image becomes the same size as the object and the magnitude of the image distance increases without limit

54 •• An object is 15.0 cm in front of a converging lens that has a focal length equal to 15.0 cm. A second converging lens that also has a focal length equal to15.0 cm is located 20.0 cm in back of the first. (a) Find the location of the final image and describe its properties (for example, real and inverted) and (b) draw a ray diagram to corroborate your answers to Part (a).

Picture the Problem We can apply the thin-lens equation to find the image formed in the first lens and then use this image as the object for the second lens.

(a) Apply the thin-lens equation to express the location of the image formed by the first lens:

$$s_1' = \frac{f_1 s_1}{s_1 - f_1} \qquad (1)$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(15.0\,\text{cm})(15.0\,\text{cm})}{15.0\,\text{cm} - 15.0\,\text{cm}} = \infty$$

i.e., no image is formed by the first lens.

With $s_1' = \infty$, the thin-lens equation applied to the second lens becomes:

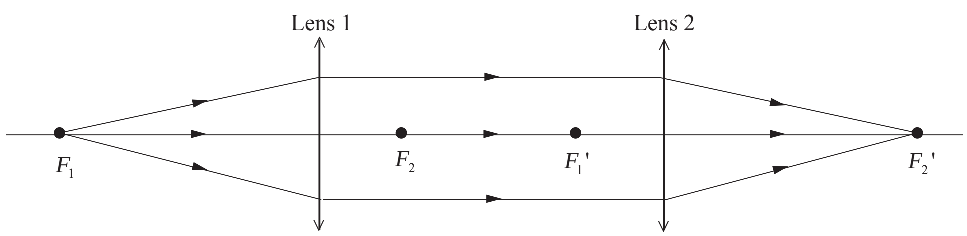
$$\frac{1}{s_2'} = \frac{1}{f_2} \Rightarrow s_2' = f_2 = \boxed{15.0\,\text{cm}}$$

The overall magnification of the two-lens system is the magnification of the second lens:

$$m = m_2 = -\frac{s_2'}{s_1} = -\frac{15.0\text{ cm}}{15.0\text{ cm}} = \boxed{-1.00}$$

The final image is 50 cm from the object, real, inverted, and the same size as the object.

(*b*) A corroborating ray diagram is shown below:



55 •• **[SSM]** An object is 15.0 cm in front of a converging lens that has a focal length equal to 15.0 cm. A diverging lens that has a focal length whose magnitude is equal to 15.0 cm is located 20.0 cm in back of the first. (*a*) Find the location of the final image and describe its properties (for example, real and inverted) and (*b*) draw a ray diagram to corroborate your answers to Part (*a*).

Picture the Problem We can apply the thin-lens equation to find the image formed in the first lens and then use this image as the object for the second lens.

Apply the thin-lens equation to express the location of the image formed by the first lens:

$$s_1' = \frac{f_1 s_1}{s_1 - f_1} \quad (1)$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(15.0\,\text{cm})(15.0\,\text{cm})}{15.0\,\text{cm} - 15.0\,\text{cm}} = \infty$$

With $s'_1 = \infty$, the thin-lens equation applied to the second lens becomes:

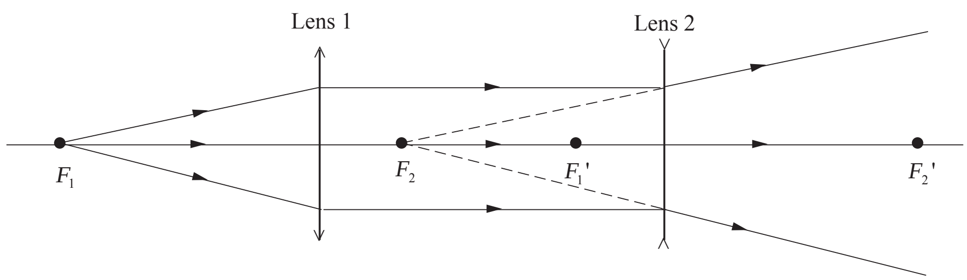
$$\frac{1}{s_2'} = \frac{1}{f_2} \Rightarrow s_2' = f_2 = \boxed{-15.0\,\text{cm}}$$

The overall magnification of the two-lens system is the magnification of the second lens:

$$m = m_2 = -\frac{s_2'}{s_1} = -\frac{-15.0\,\text{cm}}{15.0\,\text{cm}} = \boxed{1.00}$$

The final image is 20 cm from the object, virtual, erect, and the same size as the object.

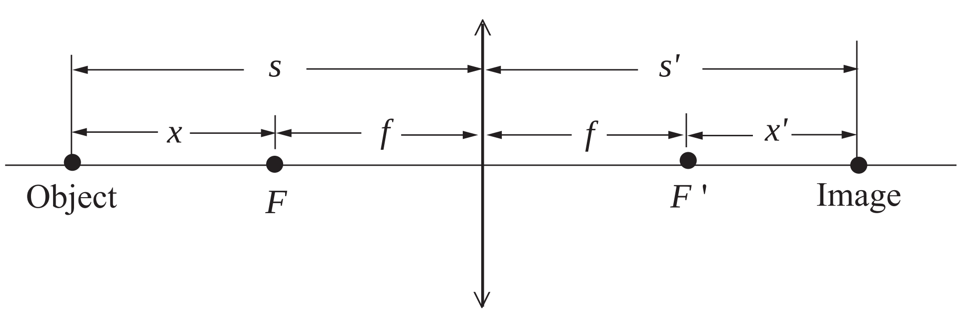
A corroborating ray diagram follows:



56 ••• In a convenient form of the thin-lens equation used by Newton, the object and image distances x and x' are measured from the focal points F and F', and not from the center of the lens. (a) Indicate x and x' on a sketch of a lens and show that if $x = s - f$ and $x' = s' - f$, the thin-lens equation (Equation 32-12) can be rewritten as $xx' = f^2$. (b) Show that the lateral magnification is given by $m = -x'/f = -f/x$.

Picture the Problem We can substitute $x = s - f$ and $x' = s' - f$ in the thin-lens equation and the equation for the lateral magnification of an image to obtain Newton's equations.

(a) The variables x, f, s ,and s' are shown in the following sketch:



Express the thin-lens equation: $\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$

If $x = s - f$ and $x' = s' - f$, then: $\frac{1}{x+f}+\frac{1}{x'+f}=\frac{1}{f}$

Expand this expression to obtain:

$$f\left(x'+x+2f\right)=\left(x+f\right)\left(x'+f\right)$$
$$=xx'+xf+x'f+f^2$$

or, simplifying, $\boxed{xx' = f^2}$ (1)

(*b*) The lateral magnification is:

$$m=-\frac{s'}{s}$$

or, because $x = s - f$ and $x' = s' - f$,

$$m=-\frac{x'+f}{x+f}$$

Solve equation (1) for x: $x=\frac{f^2}{x'}$

Substitute for x and simplify to obtain:

$$m=-\frac{x'+f}{\frac{f^2}{x'}+f}=-\frac{x'+f}{\frac{f\left(f+x'\right)}{x'}}=\boxed{-\frac{x'}{f}}$$

The lateral magnification is also given by:

$$m=-\frac{x'+f}{x+f}$$

From equation (1) we have: $x'=\frac{f^2}{x}$

Substitute to obtain:

$$m=-\frac{\frac{f^2}{x}+f}{x+f}=-\frac{f\left(\frac{f}{x}+1\right)}{x\left(1+\frac{f}{x}\right)}=\boxed{-\frac{f}{x}}$$

57 ••• [SSM] In *Bessel's method* for finding the focal length f of a lens, an object and a screen are separated by distance L, where $L > 4f$. It is then possible to place the lens at either of two locations, both between the object and the screen, so that there is an image of the object on the screen, in one case magnified and in the other case reduced. Show that if the distance between these two lens locations is D, then the focal length is given by $f = \frac{1}{4}\left(L^2 - D^2\right)/L$. *Hint: Refer to Figure 32-60.*

Picture the Problem The ray diagram shows the two lens positions and the corresponding image and object distances (denoted by the numerals 1 and 2). We can use the thin-lens equation to relate the two sets of image and object distances to the focal length of the lens and then use the hint to express the relationships between these distances and the distances D and L to eliminate s_1, s_1', s_2, and s_2' and obtain an expression relating f, D, and L.

Relate the image and object distances for the two lens positions to the focal length of the lens:

$$\frac{1}{s_1}+\frac{1}{s_1'}=\frac{1}{f} \text{ and } \frac{1}{s_2}+\frac{1}{s_2'}=\frac{1}{f}$$

Solve for f to obtain:

$$f=\frac{s_1 s_1'}{s_1+s_1'}=\frac{s_2 s_2'}{s_2+s_2'} \quad (1)$$

The distances D and L can be expressed in terms of the image and object distances:

$$L = s_1 + s_1' = s_2 + s_2'$$
and
$$D = s_2 - s_1 = s_1' - s_2'$$

Substitute for the sums of the image and object distances in equation (1) to obtain:

$$f=\frac{s_1 s_1'}{L}=\frac{s_2 s_2'}{L}$$

From the hint:

$$s_1 = s_2' \text{ and } s_1' = s_2$$

Hence $L = s_1 + s_2$ and:

$$L - D = 2s_1 \text{ and } L + D = 2s_2$$

Take the product of $L - D$ and $L + D$ to obtain:

$$\begin{aligned}(L-D)(L+D) &= L^2 - D^2\\ &= 4s_1 s_2 = 4s_1 s_1'\end{aligned}$$

From the thin-lens equation:

$$4s_1 s_2 = rs_1 s_1' = 4fL$$

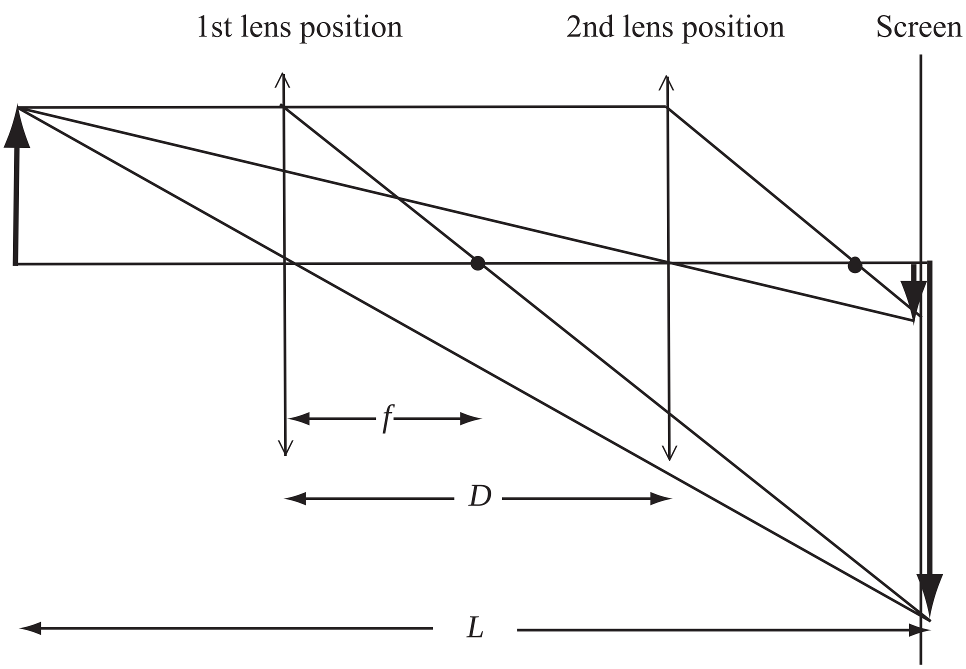
Substitute to obtain:

$$4fL = L^2 - D^2 \Rightarrow f = \boxed{\frac{L^2 - D^2}{4L}}$$

58 •• You are working for an optician during the summer. The optician needs to measure an unknown focal length and you suggest using *Bessel's method* (see Problem 56) which you used during a physics lab. You set the object-to-image distance at 1.70 m. The lens position is adjusted to get a sharp image on the screen. A second sharp image is found when the lens is moved a distance of 72 cm from its first location. (*a*) Sketch the ray diagram for the two locations. (*b*) Find the focal length of the lens using Bessel's method. (*c*) What are the two locations of the lens with respect to the object? (*d*) What are the magnifications of the images when the lens is in the two locations?

Picture the Problem We can use results obtained in Problem 57 to find the focal length of the lens and the two locations of the lens with respect to the object. Let 1 refer to the first lens position and 2 to the second lens position.

(*a*) The distances defined in Problem 57 have been identified in the following ray diagram. Note that, for clarity, the two images have been slightly offset from the plane of the screen.



(*b*) From Problem 57 we have:

$$f = \frac{L^2 - D^2}{4L}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{(170\,\text{cm})^2 - (72\,\text{cm})^2}{4(170\,\text{cm})} = \boxed{35\,\text{cm}}$$

(*c*) Solve the thin-lens equation for the image distance to obtain:

$$s' = \frac{fs}{f - s} \qquad (1)$$

In Problem 57 it was established that:

$$L - D = 2s_1 \text{ and } L + D = 2s_2$$

Solve for s_1 and s_2:

$$s_1 = \frac{L-D}{2} \text{ and } s_2 = \frac{L+D}{2}$$

Substitute numerical values and evaluate s_1 and s_2:

$$s_1 = \frac{170\,\text{cm} - 72\,\text{cm}}{2} = \boxed{49\,\text{cm}}$$

and

$$s_2 = \frac{170\,\text{cm} + 72\,\text{cm}}{2} = \boxed{121\,\text{cm}}$$

(*d*) The magnification when the lens was in its first position is given by:

$$m_1 = -\frac{s'_1}{s_1} = -\frac{D - s_1}{s_1}$$

Substituting numerical values yields:

$$m_1 = -\frac{170\text{ cm} - 49\text{ cm}}{49\text{ cm}} = \boxed{-2.5}$$

The magnification when the lens was in its second position is given by:

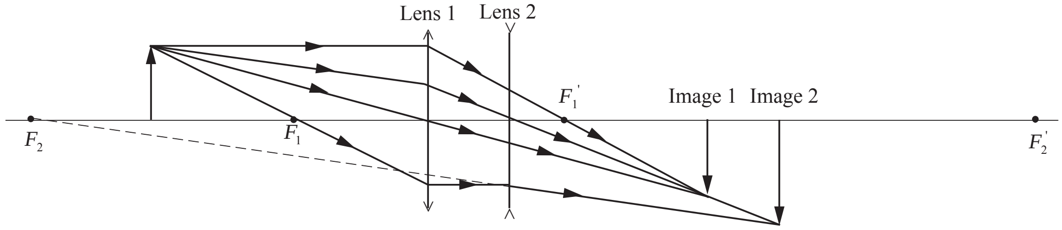
$$m_2 = -\frac{s'_2}{s_2} = -\frac{L - s_2}{s_2}$$

Substitute numerical values and evaluate m_2:

$$m_2 = -\frac{170\text{ cm} - 121\text{ cm}}{121\text{ cm}} = \boxed{-0.41}$$

59 ••• An object is 17.5 cm to the left of a lens that has a focal length of +8.50 cm. A second lens, which has a focal length of −30.0 cm, is 5.00 cm to the right of the first lens. (*a*) Find the distance between the object and the final image formed by the second lens. (*b*) What is the overall magnification? (*c*) Is the final image real or virtual? Is the final image upright or inverted?

Picture the Problem The ray diagram shows four rays from the head of the object that locate images I_1 and I_2. We can use the thin-lens equation to find the location of the image formed in the positive lens and then, knowing the separation of the two lenses, determine the object distance for the second lens and apply the thin lens a second time to find the location of the final image.



(*a*) Express the object-to-image distance *d*:

$$d = s_1 + 5\,\text{cm} + s_2' \qquad (1)$$

Apply the thin-lens equation to the positive lens:

$$\frac{1}{s_1} + \frac{1}{s_1'} = \frac{1}{f_1} \Rightarrow s_1' = \frac{f_1 s_1}{s_1 - f_1}$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(8.50\,\text{cm})(17.5\,\text{cm})}{17.5\,\text{cm} - 8.50\,\text{cm}} = 16.53\,\text{cm}$$

Find the object distance for the negative lens:

$$s_2 = 5.00\,\text{cm} - s_1' = 5.00\,\text{cm} - 16.53\,\text{cm}$$
$$= -11.53\,\text{cm}$$

The image distance s_2' is given by:

$$s_2' = \frac{f_2 s_2}{s_2 - f_2}$$

Substitute numerical values and evaluate s_2':

$$s_2' = \frac{(-30.0\,\text{cm})(-11.53\,\text{cm})}{-11.53\,\text{cm} - (-30.0\,\text{cm})} = 18.73\,\text{cm}$$

Substitute numerical values in equation (1) and evaluate *d*:

$$d = 17.5\,\text{cm} + 5.00\,\text{cm} + 18.73\,\text{cm}$$
$$= \boxed{41\,\text{cm}}$$

and the final image is 18.7 cm to the right of the second lens.

(*b*) The overall lateral magnification is given by:

$$m = m_1 m_2$$

Express m_1 and m_2:

$$m_1 = -\frac{s_1'}{s_1} \text{ and } m_2 = -\frac{s_2'}{s_2}$$

Substitute for m_1 and m_2 to obtain:

$$m = \left(-\frac{s_1'}{s_1}\right)\left(-\frac{s_2'}{s_2}\right) = \frac{s_1' s_2'}{s_1 s_2}$$

Substitute numerical values and evaluate *m*:

$$m = \frac{(16.53\,\text{cm})(18.73\,\text{cm})}{(17.5\,\text{cm})(-11.53\,\text{cm})} = \boxed{-1.53}$$

(*c*) Because $m < 0$, the image is inverted. Because $s_2' > 0$, the image is real.

Aberrations

60 • Chromatic aberration is a common defect of (*a*) concave and convex lenses, (*b*) concave lenses only, (*c*) concave and convex mirrors, (*d*) all lenses and mirrors.

Determine the Concept Chromatic aberrations are a consequence of the differential refraction of light of differing wavelengths by lenses. $\boxed{(a)}$ is correct.

61 • Discuss some of the reasons why most telescopes that are used by astronomers are reflecting rather than refracting telescopes.

Determine the Concept Reasons for the preference for reflectors include: 1) no chromatic aberrations, 2) cheaper to shape one side of a piece of glass than to shape both sides, 3) reflectors can be more easily supported from rear instead of edges, preventing sagging and focal length changes, and 4) support from rear makes larger sizes easier to handle.

62 • A symmetric double-convex lens has radii of curvature equal to 10.0 cm. It is made from glass that has an index of refraction equal to 1.530 for blue light and to 1.470 for red light. Find the focal length of this lens for (*a*) red light and (*b*) blue light.

Picture the Problem We can use the lens-maker's equation to find the focal length the this lens for the two colors of light.

The lens-maker's equation relates the radii of curvature and the index of refraction to the focal length of the lens:

$$\frac{1}{f}=\left(\frac{n}{n_{\text{air}}}-1\right)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

(*a*) For red light:

$$\frac{1}{f_{\text{red}}}=\left(\frac{1.470}{1.00}-1\right)\left(\frac{1}{10.0\,\text{cm}}-\frac{1}{-10.0\,\text{cm}}\right)$$

and $f_{\text{red}}=\boxed{10.6\,\text{cm}}$

(*b*) For blue light:

$$\frac{1}{f_{\text{blue}}}=\left(\frac{1.530}{1.00}-1\right)\left(\frac{1}{10.0\,\text{cm}}-\frac{1}{-10.0\,\text{cm}}\right)$$

and $f_{\text{blue}}=\boxed{9.43\,\text{cm}}$

The Eye

63 • Find the change in the focal length of the eye when an object originally at 3.0 m is brought to 30 cm from the eye.

Picture the Problem We can apply the thin-lens equation for the two values of s to find Δf.

Express the change Δf in the focal length:

$$\Delta f = f_{s=0.30\,\text{m}} - f_{s=3.0\,\text{m}}$$

Solve the thin-lens equation for s:

$$f = \frac{ss'}{s'+s}$$

Substitute for f to obtain:

$$\Delta f = \frac{s_{0.30\,\text{m}}s'_{0.30\,\text{m}}}{s'_{0.30\,\text{m}} + s_{0.30\,\text{m}}} - \frac{s_{3.0\,\text{m}}s'_{3.0\,\text{m}}}{s'_{3.0\,\text{m}} + s_{3.0\,\text{m}}}$$

Because $s'_{3.0\,\text{m}} = s'_{0.30\,\text{m}}$:

$$\Delta f = s'_{3.0\,\text{m}}\left[\frac{s_{0.30\,\text{m}}}{s'_{0.30\,\text{m}} + s_{0.30\,\text{m}}} - \frac{s_{3.0\,\text{m}}}{s'_{3.0\,\text{m}} + s_{3.0\,\text{m}}}\right]$$

Substitute numerical values and evaluate Δf:

$$\Delta f = (2.5\,\text{cm})\left[\frac{30\,\text{cm}}{2.5\,\text{cm}+30\,\text{cm}} - \frac{300\,\text{cm}}{2.5\,\text{cm}+300\,\text{cm}}\right] = -0.172\,\text{cm} = \boxed{-1.7\,\text{mm}}$$

64 • A farsighted person requires lenses that have powers equal to 1.75 D to read comfortably from a book that is 25.0 cm from his eyes. What is that person's near point without the lenses?

Picture the Problem We can use the thin-lens equation and the definition of the power of a lens to express the near point distance as a function of P and s.

From the thin-lens equation we have:

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}=P \Rightarrow s'=\frac{s}{Ps-1}$$

Substitute numerical values and evaluate s':

$$s' = \frac{25.0\,\text{cm}}{(1.75\,\text{m}^{-1})(0.250\,\text{m})-1} = -44.4\,\text{cm}$$

The person's near point without lenses is $\boxed{44.4\text{ cm}}$.

65 • [SSM] If two point objects close together are to be seen as two distinct objects, the images must fall on the retina on two different cones that are not adjacent. That is, there must be an unactivated cone between them. The separation of the cones is about 1.00 μm. Model the eye as a uniform 2.50-cm-diameter sphere that has a refractive index of 1.34. (*a*) What is the smallest angle the two points can subtend? (See Figure 32-61.) (*b*) How close together can two points be if they are 20.0 m from the eye?

Picture the Problem We can use the relationship between a distance measured along the arc of a circle and the angle subtended at its center to approximate the smallest angle the two points can subtend and the separation of the two points 20.0 m from the eye.

(*a*) Relate θ_{min} to the diameter of the eye and the distance between the activated cones:

$$d_{\text{eye}}\theta_{\text{min}} \approx 2.00\,\mu\text{m} \Rightarrow \theta_{\text{min}} = \frac{2.00\,\mu\text{m}}{d_{\text{eye}}}$$

Substitute numerical values and evaluate θ_{min}:

$$\theta_{\text{min}} = \frac{2.00\,\mu\text{m}}{2.50\,\text{cm}} = \boxed{80.0\,\mu\text{rad}}$$

(*b*) Let D represent the separation of the points R = 20.0 m from the eye to obtain:

$$D = R\theta_{\text{min}} = (20.0\,\text{m})(80.0\,\mu\text{rad}) = \boxed{1.60\,\text{mm}}$$

66 • Suppose the eye were designed like a camera that has a lens of fixed focal length equal to 2.50 cm that could move toward or away from the retina. Approximately how far would the lens have to move to focus the image of an object 25.0 cm from the eye onto the retina? *Hint: Find the distance from the retina to the image behind it for an object at 25.0 cm.*

Picture the Problem We can use the thin-lens equation to find the distance from the lens to the image and then take their difference to find the distance the lens would have to be moved.

Express the distance d that the lens would have to move:

$$d = s' - f$$

Solve the thin-lens equation for s':

$$s' = \frac{fs}{s-f}$$

Substitute for s' to obtain:

$$d=\frac{fs}{s-f}-f$$

Substitute numerical values and evaluate d:

$$d=\frac{(2.50\,\text{cm})(25.0\,\text{cm})}{25.0\,\text{cm}-2.50\,\text{cm}}-2.50\,\text{cm}$$
$$=0.28\,\text{cm}$$

That is, the lens would have to move $\boxed{0.28\,\text{cm}}$ toward the object.

67 •• **[SSM]** The Model Eye I: A simple model for the eye is a lens that has a variable power P located a fixed distance d in front of a screen, with the space between the lens and the screen filled by air. This "eye" can focus for all values of object distance s such that $x_{np} \le s \le x_{fp}$ where the subscripts on the variables refer to "near point" and "far point" respectively. This "eye" is said to be normal if it can focus on very distant objects. (*a*) Show that for a normal "eye," of this type, the required minimum value of P is given by $P_{min}=1/d$. (*b*) Show that the maximum value of P is given by $P_{max}=1/x_{np}+1/d$. (*c*) The difference between the maximum and minimum powers, symbolized by A, is defined as $A=P_{max}-P_{min}$ and is called the *accommodation*. Find the minimum power and accommodation for this model eye that has a screen distance of 2.50 cm, a far point distance of infinity and a near point distance of 25.0 cm.

Picture the Problem The thin-lens equation relates the image and object distances to the power of a lens.

(*a*) Use the thin-lens equation to relate the image and object distances to the power of the lens:

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}=P \qquad (1)$$

Because $s'=d$ and, for a distance object, $s=\infty$:

$$P_{min}=\frac{1}{s'}=\boxed{\frac{1}{d}}$$

(*b*) If x_{np} is the closest distance an object could be and still remain in clear focus on the screen, equation (1) becomes:

$$P_{max}=\boxed{\frac{1}{x_{np}}+\frac{1}{d}}$$

(*c*) Use our result in (*a*) to obtain:

$$P_{min}=\frac{1}{2.50\,\text{cm}}=\boxed{40.0\,\text{D}}$$

Use the results of (a) and (b) to express the accommodation of the model eye:

$$A = P_{\max} - P_{\min} = \frac{1}{x_{\text{np}}} + \frac{1}{d} - \frac{1}{d} = \frac{1}{x_{\text{np}}}$$

Substitute numerical values and evaluate A:

$$A = \frac{1}{25.0\,\text{cm}} = \boxed{4.00\,\text{D}}$$

68 •• The Model Eye II: In an eye that exhibits nearsightedness, the eye cannot focus on distant objects. (a) Show that for a nearsighted model eye capable of focusing out to a maximum distance x_{fp}, the minimum value of the power P is greater than that of a normal eye (that has a far point at infinity) and is given by $P_{\min} = 1/x_{\text{fp}} + 1/d$. (b) To correct for nearsightedness, a contact lens may be placed directly in front of the model-eye's lens. What power contact lens would be needed to correct the vision of a nearsighted model eye that has a far point distance of 50.0 cm?

Picture the Problem The thin-lens equation relates the image and object distances to the power of a lens.

(a) Use the thin-lens equation to relate the image and object distances to the power of the lens:

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f} = P$$

Because $s' = d$ and $s = x_{\text{fp}}$:

$$P_{\min} = \boxed{\frac{1}{x_{\text{fp}}} + \frac{1}{d}}$$

(b) To correct for the nearsightedness of this eye, we need a lens that will form an image 25.0 cm in front of the eye of an object at the eye's far point:

$$P_{\min} = \frac{1}{50.0\,\text{cm}} + \frac{1}{-25.0\,\text{cm}} = \boxed{-2.00\,\text{D}}$$

69 •• The Model Eye III: In an eye that exhibits farsightedness, the eye may be able to focus on distant objects but cannot focus on close objects. (a) Show that for a farsighted model eye capable of focusing only as close as a distance x'_{np}, the maximum value of the power P is given by $P_{\max} = 1/x'_{\text{np}} + 1/d$. (b) Show that, compared to a model eye capable of focusing as close as a distance x_{np} (where $x_{\text{np}} < x'_{\text{np}}$), the maximum power of the farsighted lens is too small by $1/x_{\text{np}} - 1/x'_{\text{np}}$. (c) What power contact lens would be needed to correct the vision of a farsighted model eye, with x'_{np} = 150 cm, so that the eye may focus on objects as close as 15 cm?

Picture the Problem The thin-lens equation relates the image and object distances to the power of a lens.

(*a*) Use the thin-lens equation to relate the image and object distances to the power of the lens:

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}=P$$

Because $s' = d$ and $s = x'_{np}$:

$$P'_{max}=\boxed{\frac{1}{x'_{np}}+\frac{1}{d}} \qquad (1)$$

(*b*) For a normal eye:

$$P_{max}=\frac{1}{x_{np}}+\frac{1}{d} \qquad (2)$$

The amount by which the power of the lens is too small is the difference between equations (2) and (1):

$$P_{max}-P'_{max}=\frac{1}{x_{np}}+\frac{1}{d}-\left(\frac{1}{x'_{np}}+\frac{1}{d}\right)$$
$$=\boxed{\frac{1}{x_{np}}-\frac{1}{x'_{np}}}$$

(*c*) For x_{np} = 15 cm and x'_{np} = 150 cm:

$$P_{max}-P'_{max}=\frac{1}{15\,\text{cm}}-\frac{1}{150\,\text{cm}}$$
$$=\boxed{6.0\,\text{D}}$$

70 •• A person who has a near point of 80 cm needs to read from a computer screen that is only 45 cm from her eye. (*a*) Find the focal length of the lenses in reading glasses that will produce an image of the screen at a distance of 80 cm from her eye. (*b*) What is the power of the lenses?

Picture the Problem We can use the thin-lens equation to find *f* and the definition of the power of a lens to find *P*.

(*a*) Solve the thin-lens equation for *f*:

$$f=\frac{ss'}{s'+s}$$

Noting that $s' < 0$, substitute numerical values and evaluate *f*:

$$f=\frac{(45\,\text{cm})(-80\,\text{cm})}{-80\,\text{cm}+45\,\text{cm}}=103\,\text{cm}$$
$$=\boxed{1.0\,\text{m}}$$

(*b*) Use the definition of the power of a lens to obtain:

$$P=\frac{1}{f}=\frac{1}{1.03\,\text{m}}=\boxed{0.97\,\text{D}}$$

71 •• A nearsighted person cannot focus clearly on objects that are more distant than 2.25 m from her eye. What power lenses are required for her to see distant objects clearly?

Picture the Problem We can use the thin-lens equation to find *f* and the definition of the power of a lens to find *P*.

Express the required power of the lens:

$$P = \frac{1}{f}$$

The thin-lens equation is:

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f}$$

For $s = \infty$:

$$\frac{1}{s'} = \frac{1}{f} \Rightarrow f = s'$$

Substitute for *f* to obtain:

$$P = \frac{1}{s'}$$

Substitute for s' and evaluate *P*:

$$P = \frac{1}{2.25\,\text{m}} = \boxed{0.444\,\text{D}}$$

72 •• Because the index of refraction of the lens of the eye is not very different from that of the surrounding material, most of the refraction takes place at the cornea, where the index changes abruptly from 1.00 (air) to approximately 1.38. (*a*) Modeling the cornea, aqueous humor, lens and vitreous humor is a transparent homogeneous solid sphere that has an index of refraction of 1.38, calculate the sphere's radius if it focuses parallel light on the retina a distance 2.50 cm away. (*b*) Do you expect your result to be larger or smaller than the actual radius of the cornea? Explain your answer.

Picture the Problem We can use the equation for refraction at a single surface (Equation 32-6) with $s = \infty$ to find the radius of the cornea modeled as a homogeneous sphere with an index of refraction of 1.38.

(*a*) Use Equation 32-6 to relate the radius of the cornea to its index of refraction and that of air:

$$\frac{n_1}{s} + \frac{n_2}{s'} = \frac{n_2 - n_1}{r}$$

Because $n_2 = n$, $n_1 = 1$, and $s = \infty$:

$$\frac{n}{s'} = \frac{n-1}{r} \Rightarrow r = \frac{s'(n-1)}{n} = \left(1 - \frac{1}{n}\right)s'$$

Substitute numerical values and evaluate r:

$$r = \left(1 - \frac{1}{1.38}\right)(2.50\,\text{cm}) = \boxed{0.688\,\text{cm}}$$

(*b*) The calculated value for the distance to the retina is too large. The eye is not a homogeneous sphere, and in a real eye additional refraction occurs at the lens. By modeling the eye as a homogeneous solid sphere we are ignoring the refraction that takes place at the lens.

73 •• The near point of a certain person's eyes is 80 cm. Reading glasses are prescribed so that he can read a book at 25 cm from his eye. The glasses are 2.0 cm from the eye. What diopter lenses should be used in the glasses?

Picture the Problem We can use the definition of the power of a lens and the thin-lens equation to find the power of the lens that should be used in the glasses.

Express the power of the lens that should be used in the glasses:

$$P = P_{\text{eye}} + P_{\text{lens}} = \frac{1}{f_{\text{eye}}} + \frac{1}{f_{\text{glasses}}} \quad (1)$$

Because the glasses are 2.0 cm from the eye:

$$s' = -80\,\text{cm} + 2.0\,\text{cm} = -78\,\text{cm}$$

and

$$s = 25\,\text{cm} - 2.0\,\text{cm} = 23\,\text{cm}$$

Apply the thin-lens equation to the eye with $s' = \infty$:

$$\frac{1}{s} = \frac{1}{f_{\text{eye}}} \Rightarrow f_{\text{eye}} = s$$

Apply the thin-lens equation to the glasses with $s = \infty$:

$$\frac{1}{s'} = \frac{1}{f_{\text{glasses}}} \Rightarrow f_{\text{glasses}} = s'$$

Substitute for f_{eye} and f_{glasses} in equation (1) to obtain:

$$P = \frac{1}{s} + \frac{1}{s'}$$

Substitute numerical values and evaluate P:

$$P = \frac{1}{0.23\,\text{m}} + \frac{1}{-0.78\,\text{m}} = \boxed{3.1\,\text{D}}$$

74 ••• At age 45, a person is fitted for reading glasses that have a power equal to 2.10 D in order to read at 25 cm. By the time she reaches the age of 55, she discovers herself holding her newspaper at a distance of 40 cm in order to see it clearly with her glasses on. (*a*) Where was her near point at age 45? (*b*) Where is her near point at age 55? (*c*) What power is now required for the lenses of her reading glasses so that she can again read at 25 cm? Assume the glasses are placed 2.2 cm from her eyes.

Picture the Problem We can use the thin-lens equation and the distance from her eyes to her glasses to derive an expression for the location of her near point.

(a) Express her near point, x_{np}, at age 45 in terms of the location of her glasses:

$$x_{np} = |s'| + 2.2\,\text{cm} \qquad (1)$$

Because the glasses are 2.2 cm from her eye:

$$s = 25\ \text{cm} - 2.2\ \text{cm} = 22.8\ \text{cm}$$

Apply the thin-lens equation to the glasses:

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f_{\text{glasses}}} = P$$

Solving for s' yields:

$$s' = \frac{s}{Ps - 1} = \frac{1}{P - \frac{1}{s}}$$

Substitute in equation (1) to obtain:

$$x_{np} = \left|\frac{1}{P - \frac{1}{s}}\right| + 2.2\,\text{cm} \qquad (2)$$

Substitute numerical values and evaluate x_{np}:

$$x_{np} = \left|\frac{1}{2.10\,\text{m}^{-1} - \frac{1}{0.228\,\text{m}}}\right| + 2.2\,\text{cm} = \boxed{46\,\text{cm}}$$

(b) At age 55:

$$s = 40\ \text{cm} - 2.2\ \text{cm} = 37.8\ \text{cm}$$

Substitute numerical values in equation (2) and evaluate s':

$$x_{np} = \left|\frac{1}{2.10\,\text{m}^{-1} - \frac{1}{0.378\,\text{m}}}\right| + 2.2\,\text{cm} = \boxed{1.9\ \text{m}}$$

(c) Solve the thin-lens equation for f:

$$f = \frac{ss'}{s' + s}$$

From the definition of P:

$$P = \frac{1}{f} = \frac{s' + s}{s's}$$

For s = 22.8 cm and s' = 183.3 cm:

$$P = \frac{183.3\,\text{cm} + 22.8\,\text{cm}}{(183.3\,\text{cm})(22.8\,\text{cm})} = \boxed{4.9\,\text{D}}$$

The Simple Magnifier

75 • **[SSM]** What is the magnifying power of a lens that has a focal length equal to 7.0 cm when the image is viewed at infinity by a person whose near point is at 35 cm?

Picture the Problem We can use the definition of the magnifying power of a lens to find the magnifying power of this lens.

The magnifying power of the lens is given by:

$$M = \frac{x_{\text{np}}}{f}$$

Substitute numerical values and evaluate M:

$$M = \frac{35\,\text{cm}}{7.0\,\text{cm}} = \boxed{5.0}$$

76 •• A lens that has a focal length equal to 6.0 cm is used as a simple magnifier by one person whose near point is 25 cm and by another person whose near point is 40 cm. (*a*) What is the effective magnifying power of the lens for each person? (*b*) Compare the sizes of the images on the retinas when each person looks at the same object with the magnifier.

Picture the Problem Let the numerals 1 and 2 denote the 1st and 2nd persons, respectively. We can use the definition of magnifying power to find the effective magnifying power of the lens for each person. The relative sizes of the images on the retinas of the two persons is given by the ratio of the effective magnifying powers.

(*a*) The magnifying power of the lens is given by:

$$M = \frac{x_{\text{np}}}{f}$$

Substitute numerical values and evaluate M_1 and M_2:

$$M_1 = \frac{25\,\text{cm}}{6.0\,\text{cm}} = 4.17 = \boxed{4.2}$$

and

$$M_2 = \frac{40\,\text{cm}}{6.0\,\text{cm}} = 6.67 = \boxed{6.7}$$

If $x_{np} = 25$ cm, then $M = 4.2$, and if $x_{np} = 40$ cm, then $M = 6.7$.

(*b*) From the definition of magnifying power we have:

$$\frac{M_1}{M_2} = \frac{\dfrac{y_1}{f}}{\dfrac{y_2}{f}} = \frac{y_1}{y_2}$$

Substitute for M_1 and M_2 and evaluate the ratio of y_1 to y_2:

$$\frac{y_1}{y_2} = \frac{4.17}{6.67} = \boxed{0.63}$$

For a person with $x_{np} = 40$ cm, the image on the retina is 1.6 times larger than it is for a person with $x_{np} = 25$ cm.

77 •• [SSM] In your botany class, you examine a leaf using a convex 12-D lens as a simple magnifier. What is the angular magnification of the leaf if image formed by the lens (*a*) is at infinity and (*b*) is at 25 cm?

Picture the Problem We can use the definition of angular magnification to find the expected angular magnification if the final image is at infinity and the thin-lens equation and the expression for the magnification of a thin lens to find the angular magnification when the final image is at 25 cm.

(*a*) Express the angular magnification when the final image is at infinity:

$$M = \frac{x_{np}}{f} = x_{np}P$$

where P is the power of the lens.

Substitute numerical values and evaluate M:

$$M = (25\,\text{cm})(12\,\text{m}^{-1}) = \boxed{3.0}$$

(*b*) Express the magnification of the lens when the final image is at 25 cm:

$$m = -\frac{s'}{s}$$

Solve the thin-lens equation for s:

$$s = \frac{fs'}{s' - f}$$

Substitute for s and simplify to obtain:

$$m = -\frac{s'}{\dfrac{fs'}{s'-f}} = -\frac{s'-f}{f} = -\frac{s'}{f} + 1$$
$$= 1 - s'P$$

Substitute numerical values and evaluate m:

$$m = 1 - (-0.25\,\text{m})(12\,\text{m}^{-1}) = \boxed{4.0}$$

The Microscope

78 •• Your laboratory microscope objective has a focal length of 17.0 mm. It forms an image of a tiny specimen at 16.0 cm from its second focal point. (*a*) How far from the objective is the specimen located? (*b*) What is the magnifying power for you if your near point distance is 25.0 cm and the focal length of the eyepiece is 51.0 mm?

Picture the Problem We can use the thin-lens equation to find the location of the object and the expression for the magnifying power of a microscope to find the magnifying power of the given microscope for a person whose near point is at 25.0 cm.

(*a*) Using the thin-lens equation, relate the object distance s to the focal length of the objective lens f_0:

$$\frac{1}{s} + \frac{1}{s'} = \frac{1}{f_0} \Rightarrow s = \frac{f_0 s'}{s' - f_0}$$

The image distance for the image formed by the objective lens is:

$$s' = f_0 + L = 1.70\,\text{cm} + 16.0\,\text{cm} = 17.7\,\text{cm}$$

Substitute numerical values and evaluate s:

$$s = \frac{(1.70\,\text{cm})(17.7\,\text{cm})}{17.7\,\text{cm} - 1.70\,\text{cm}} = \boxed{18.8\ \text{mm}}$$

(*b*) Express the magnifying power of a microscope:

$$M = -\frac{L}{f_0}\frac{x_{\text{np}}}{f_{\text{e}}}$$

Substitute numerical values and evaluate M:

$$M = -\left(\frac{16.0\,\text{cm}}{1.70\,\text{cm}}\right)\left(\frac{25.0\,\text{cm}}{5.10\,\text{cm}}\right) = \boxed{-46.1}$$

79 •• **[SSM]** Your laboratory microscope objective has a focal length of 17.0 mm. It forms an image of a tiny specimen at 16.0 cm from its second focal point. (*a*) How far from the objective is the specimen located? (*b*) What is the magnifying power for you if your near point distance is 25.0 cm and the focal length of the eyepiece is 51.0 mm?

Picture the Problem The lateral magnification of the objective is $m_{\text{o}} = -L/f_{\text{o}}$ and the magnifying power of the microscope is $M = m_{\text{o}} M_{\text{e}}$.

(*a*) The lateral magnification of the objective is given by:

$$m_o = -\frac{L}{f_o}$$

Substitute numerical values and evaluate m_o:

$$m_o = -\frac{16\,\text{cm}}{8.5\,\text{mm}} = -18.8 = \boxed{-19}$$

(*b*) The magnifying power of the microscope is given by:

$$M = m_o M_e$$

where M_e is the angular magnification of the lens.

Substitute numerical values and evaluate M:

$$M = (-18.8)(10) = \boxed{-1.9\times10^2}$$

80 •• A crude, symmetric handheld microscope consists of two 20-D lenses fastened at the ends of a tube 30 cm long. (*a*) What is the tube length of this microscope? (*b*) What is the lateral magnification of the objective? (*c*) What is the magnifying power of the microscope? (*d*) How far from the objective should the object be placed?

Picture the Problem We can find the tube length from the length of the tube to which the lenses are fastened and the focal lengths of the objective and eyepiece. We can use their definitions to find the lateral magnification of the objective and the magnifying power of the microscope. The distance of the object from the objective can be found using the thin-lens equation.

(*a*) The tube length L is given by:

$$L = D - f_o - f_e$$
$$= 0.30\,\text{m} - \frac{2}{20\,\text{m}^{-1}} = \boxed{20\,\text{cm}}$$

(*b*) The lateral magnification of the objective m_o is given by:

$$m_o = -\frac{L}{f_o} = -\frac{20\,\text{cm}}{5.0\,\text{cm}} = \boxed{-4.0}$$

(*c*) The magnifying power of the microscope is given by:

$$M = m_o M_e = m_o \frac{x_{np}}{f_e}$$

Substitute numerical values and evaluate M:

$$M = (-4)\frac{25\,\text{cm}}{5.0\,\text{cm}} = \boxed{-20}$$

(*d*) From the thin-lens equation we have:

$$\frac{1}{s_o} + \frac{1}{s_o'} = \frac{1}{f_o}$$

where $s_o' = f_o + L$

Substitute for s_o' to obtain:

$$\frac{1}{s_o}+\frac{1}{f_o+L}=\frac{1}{f_o}\Rightarrow s_o=\frac{f_o(f_o+L)}{L}$$

Substitute numerical values and evaluate s_o:

$$s_o=\frac{(5.0\,\text{cm})(5.0\,\text{cm}+20\,\text{cm})}{20\,\text{cm}}=\boxed{6.3\,\text{cm}}$$

81 •• A compound microscope has an objective lens that has a power of 45 D and an eyepiece that has a power of 80 D. The lenses are separated by 28 cm. Assuming that the final image is formed by the microscopy is 25 cm from the eye, what is the magnifying power?

Picture the Problem The magnifying power of a compound microscope is the product of the magnifying powers of the objective and the eyepiece.

Express the magnifying power of the microscope in terms of the magnifying powers of the objective and eyepiece:

$$M=m_o m_e \qquad (1)$$

The magnification of the eyepiece is given by:

$$m_e=\frac{x_{np}}{f_e}+1=P_e x_{np}+1$$

The magnification of the objective is given by:

$$m_o=-\frac{L}{f_o}$$

where $L=D-f_o-f_e$

Substitute for L to obtain:

$$m_o=-\frac{D-f_o-f_e}{f_o}$$

Substitute for m_e and m_o in equation (1) to obtain:

$$M=(P_e x_{np}+1)\left(-\frac{D-f_o-f_e}{f_o}\right)$$

Substitute numerical values and evaluate M:

$$M=[(80\,\text{D})(0.25\,\text{m})+1]\left(-\frac{28\,\text{cm}-2.22\,\text{cm}-1.25\,\text{cm}}{2.22\,\text{cm}}\right)=\boxed{-230}$$

82 ••• A microscope has a magnifying power of 600. The eyepiece has an angular magnification of 15.0. The objective lens is 22.0 cm from the eyepiece. Calculate (*a*) the focal length of the eyepiece, (*b*) the location of the object so that it is in focus for a normal relaxed eye, and (*c*) the focal length of the objective lens.

Picture the Problem We can find the focal length of the eyepiece from its angular magnification and the near point of a normal eye. The location of the object such that it is in focus for a normal relaxed eye can be found from the lateral magnification of the eyepiece and the magnifying power of the microscope. Finally, we can use the thin-lens equation to find the focal length of the objective lens.

(*a*) The focal length of the eyepiece is related to its angular magnifying power:

$$M_e = \frac{x_{np}}{f_e} \Rightarrow f_e = \frac{x_{np}}{M_e}$$

Substitute numerical values and evaluate f_e:

$$f_e = \frac{25.0\,\text{cm}}{15.0} = \boxed{1.67\,\text{cm}}$$

(*b*) Relate s to s' through the lateral magnification of the objective:

$$m_o = -\frac{s'}{s} \Rightarrow s = -\frac{s'}{m_o}$$

Relate the magnifying power of the microscope M to the lateral magnification of its objective m_0 and the angular magnification of its eyepiece M_e:

$$M = m_o M_e \Rightarrow m_o = \frac{M}{M_e}$$

Substitute for m_o to obtain:

$$s = -\frac{s' M_e}{M}$$

Evaluate s':

$$s' = 22\,\text{cm} - f_e$$
$$= 22\,\text{cm} - 1.67\,\text{cm} = 20.33\,\text{cm}$$

Substitute numerical values and evaluate s:

$$s = -\frac{(20.33\,\text{cm})(15.0)}{-600} = \boxed{0.508\,\text{cm}}$$

(*c*) Solving the thin-lens equation for f_o yields:

$$f_o = \frac{ss'}{s' + s}$$

Substitute numerical values and evaluate f_o:

$$f_o = \frac{(0.508\,\text{cm})(20.33\,\text{cm})}{20.33\,\text{cm} + 0.508\,\text{cm}} = \boxed{0.496\,\text{cm}}$$

The Telescope

83 • **[SSM]** You have a simple telescope that has an objective which has a focal length of 100 cm and an eyepiece which has a focal length of 5.00 cm. You are using it to look at the moon, which subtends an angle of about 9.00 mrad. (*a*) What is the diameter of the image formed by the objective? (*b*) What angle is subtended by the image formed at infinity by the eyepiece? (*c*) What is the magnifying power of your telescope?

Picture the Problem Because of the great distance to the moon, its image formed by the objective lens is at the focal point of the objective lens and we can use $D = f_o\theta$ to find the diameter D of the image of the moon. Because angle subtended by the final image at infinity is given by $\theta_e = M\theta_o = M\theta$, we can solve (*b*) and (*c*) together by first using $M = -f_o/f_e$ to find the magnifying power of the telescope.

(*a*) Relate the diameter D of the image of the moon to the image distance and the angle subtended by the moon:

$$D = s_o'\theta$$

Because the image of the moon is at the focal point of the objective lens:

$$s_o' = f_o \text{ and } D = f_o\theta$$

Substitute numerical values and evaluate D:

$$D = (100\,\text{cm})(9.00\,\text{mrad}) = \boxed{9.00\,\text{mm}}$$

(*b*) and (*c*) Relate the angle subtended by the final image at infinity to the magnification of the telescope and the angle subtended at the objective:

$$\theta_e = M\theta_o = M\theta$$

Express the magnifying power of the telescope:

$$M = -\frac{f_o}{f_e}$$

Substitute numerical values and evaluate M and θ_e:

$$M = -\frac{100\,\text{cm}}{5.00\,\text{cm}} = \boxed{-20.0}$$

and

$$\theta_e = |-20.0|(9.00\,\text{mrad}) = \boxed{180\ \text{mrad}}$$

84 • The objective lens of the refracting telescope at the Yerkes Observatory has a focal length of 19.5 m. The moon subtends an angle of about 9.00 mrad. When the telescope is used to look at the moon, what is the diameter of the image of the moon formed by the objective?

Picture the Problem Because of the great distance to the moon, its image formed by the objective lens is at the focal point of the objective lens and we can use $D = f_o\theta$ to find the diameter D of the image of the moon.

Relate the diameter D of the image of the moon to the image distance and the angle subtended by the moon:

$$D = s_o'\theta$$

Because the image of the moon is at the focal point of the objective lens:

$$s_o' = f_o \text{ and } D = f_o\theta$$

Substitute numerical values and evaluate D:

$$D = (19.5\,\text{m})(9.00\,\text{mrad}) = \boxed{17.6\,\text{cm}}$$

85 •• The 200-in (5.08-m) diameter mirror of the reflecting telescope at Mt. Palomar has a focal length of 16.8 m. (*a*) By what factor is the light-gathering power increased over the 40.0-in (1.02-m) diameter refracting lens of the Yerkes Observatory telescope? (*b*) If the focal length of the eyepiece is 1.25 cm, what is the magnifying power of the 200-in telescope?

Picture the Problem Because the light-gathering power of a mirror is proportional to its area, we can compare the light-gathering powers of these mirrors by finding the ratio of their areas. We can use the ratio of the focal lengths of the objective and eyepiece lenses to find the magnifying power of the Palomar telescope.

(*a*) Express the ratio of the light-gathering powers of the Palomar and Yerkes mirrors:

$$\frac{P_{\text{Palomar}}}{P_{\text{Yerkes}}}=\frac{A_{\substack{\text{Palomar}\\\text{mirror}}}}{A_{\substack{\text{Yerkes}\\\text{mirror}}}}=\frac{\frac{\pi}{4}d^2_{\substack{\text{Palomar}\\\text{mirror}}}}{\frac{\pi}{4}d^2_{\substack{\text{Yerkes}\\\text{mirror}}}}=\frac{d^2_{\substack{\text{Palomar}\\\text{mirror}}}}{d^2_{\substack{\text{Yerkes}\\\text{mirror}}}}$$

Substitute numerical values and evaluate $P_{\text{Palomar}}/P_{\text{Yerkes}}$:

$$\frac{P_{\text{Palomar}}}{P_{\text{Yerkes}}}=\frac{(200\,\text{in})^2}{(40.0\,\text{in})^2}=\boxed{25.0}$$

(*b*) Express the magnifying power of the Palomar telescope:

$$M=-\frac{f_o}{f_e}$$

Substitute numerical values and evaluate M:

$$M=-\frac{16.8\,\text{m}}{1.25\,\text{cm}}=\boxed{-1340}$$

86 •• An astronomical telescope has a magnifying power of 7.0. The two lenses are 32 cm apart. Find the focal length of each lens.

Picture the Problem We can use the expression for the magnifying power of a telescope and the fact that the length of a telescope is the sum of focal lengths of its objective and eyepiece lenses to obtain simultaneous equations in f_o and f_e.

The magnifying power of the telescope is given by:

$$M=-\frac{f_o}{f_e}=-7$$

The length of the telescope is the sum of the focal lengths of the objective and eyepiece lenses:

$$L=f_o+f_e=32\,\text{cm}$$

Solve these equations simultaneously to obtain:

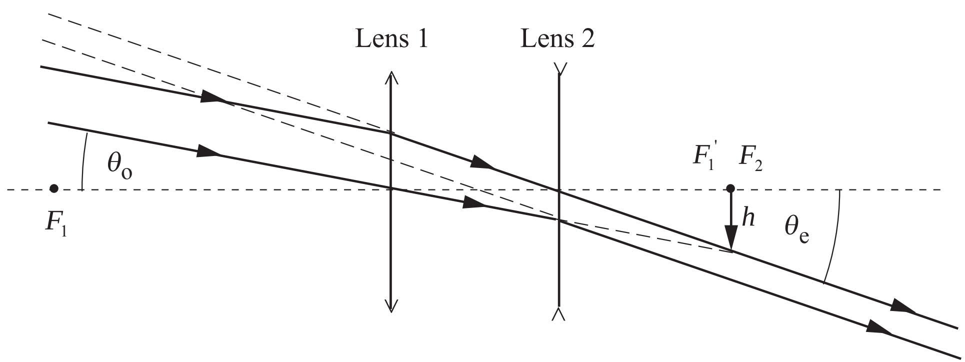
$$f_o=\boxed{28\,\text{cm}}\text{ and } f_e=\boxed{4\,\text{cm}}$$

87 •• **[SSM]** A disadvantage of the astronomical telescope for terrestrial use (for example, at a football game) is that the image is inverted. A Galilean telescope uses a converging lens as its objective, but a diverging lens as its eyepiece. The image formed by the objective is at the second focal point of the eyepiece (the focal point on the refracted side of the eyepiece), so that the final image is virtual, upright, and at infinity. (*a*) Show that the magnifying power is given by $M = -f_o/f_e$, where f_o is the focal length of the objective and f_e is that of the

eyepiece (which is negative). (*b*) Draw a ray diagram to show that the final image is indeed virtual, upright, and at infinity.

Picture the Problem The magnification of a telescope is the ratio of the angle subtended at the eyepiece lens to the angle subtended at the objective lens. We can use the geometry of the ray diagram to express both θ_e and θ_o.

(*b*) The ray diagram is shown below:



(*a*) Express the magnifying power M of the telescope:

$$M = \frac{\theta_e}{\theta_o}$$

Because the image formed by the objective lens is at the focal point, F'_1:

$$\theta_o = \frac{h}{f_o}$$

where we have assumed that $\theta_o << 1$ so that $\tan \theta_o \approx \theta_o$.

Express the angle subtended by the eyepiece:

$$\theta_e = \frac{h}{f_e}$$ where f_e is negative.

Substitute to obtain:

$$M = \frac{\frac{h}{f_e}}{\frac{h}{f_o}} = \frac{f_o}{f_e}$$

and $M = \boxed{-\frac{f_o}{f_e}}$ is positive.

Remarks: Because the object for the eyepiece is at its focal point, the image is at infinity. As is also evident from the ray diagram, the image is virtual and upright.

88 •• A Galilean telescope (see Problem 87) is designed so that the final image is at the near point, which is 25 cm (rather than at infinity). The focal length of the objective is 100 cm and the focal length of the eyepiece is –5.0 cm. (*a*) If the object distance is 30.0 m, where is the image of the objective? (*b*) What is the object distance for the eyepiece so that the final image is at the near point? (*c*) How far apart are the lenses? (*d*) If the object height is 1.5 m, what is the height of the final image? What is the angular magnification?

Picture the Problem We can use the thin-lens equation to find the image distance for the objective lens and the object distance for the eyepiece lens. The separation of the lenses is the sum of these distances. We can use the definition of the angular magnification and the angles subtended at the objective and eyepiece lenses to find the height of the final image.

(*a*) Solve the thin-lens equation for s_o':

$$s_o' = \frac{f_o s_o}{s_o - f_o}$$

Substitute numerical values and evaluate s_o':

$$s_o' = \frac{(1.00\,\text{m})(30.0\,\text{m})}{30.0\,\text{m} - 1.00\,\text{m}} = \boxed{103\text{ cm}}$$

(*b*) Solve the thin-lens equation for s_e:

$$s_e = \frac{f_e s_e'}{s_e' - f_e}$$

Noting that $s_e' = -25$ cm, substitute numerical values and evaluate s_e:

$$s_e = \frac{(-5.0\,\text{cm})(-25\,\text{cm})}{-25\,\text{cm} - (-5.0\,\text{cm})_e} = -6.25\,\text{cm}$$

$$\boxed{-6.3\,\text{cm}}$$

where the minus sign tells us that the object of the eyepiece is virtual.

(*c*) Express the separation D of the lenses:

$$D = s_o' + s_e$$

Substitute numerical values and evaluate D:

$$D = 103\,\text{cm} - 6\,\text{cm} \approx \boxed{97\text{ cm}}$$

(*d*) Express the height h' of the final image in terms of the magnification M of the telescope:

$$h' = Mh$$

The magnification of the telescope is the product of the magnifications of the objective and eyepiece lenses:

$$M = m_o m_e = \frac{s_o'}{s_o}\frac{s_e'}{s_e}$$

Substitute for M to obtain:

$$h' = \frac{s_o'}{s_o}\frac{s_e'}{s_e}h$$

Substitute numerical values and evaluate h':

$$h' = \left(\frac{103.45\,\text{cm}}{3000\,\text{cm}}\right)\left(\frac{-25\,\text{cm}}{-6.25\,\text{cm}}\right)(1.5\,\text{m}) = \boxed{21\,\text{cm}}$$

Express the angular magnification of the telescope:

$$M = \frac{\theta_e}{\theta_o}$$

The angle subtended by the object is:

$$\theta_o = \frac{h}{s_o}$$

The angle subtended by the image is:

$$\theta_e = \tan^{-1}\left(\frac{h'}{s_e}\right)$$

Substitute for θ_e and θ_o and simplify to obtain:

$$M = \frac{\tan^{-1}\left(\frac{h'}{s_e}\right)}{\frac{h}{s_o}} = \frac{s_o}{h}\tan^{-1}\left(\frac{h'}{s_e}\right)$$

Substitute numerical values and evaluate M:

$$M = \frac{30\,\text{m}}{1.5\,\text{m}}\tan^{-1}\left(\frac{20.7\,\text{cm}}{6.25\,\text{cm}}\right) = \boxed{26}$$

89 ••• If you look into the wrong end of a telescope, that is, into the objective, you will see distant objects reduced in angular size. For a refracting telescope that has an objective with a focal length equal to 2.25 m and an eyepiece with a focal length equal to 1.50 cm, by what factor is the angular size of the object changed?

Picture the Problem The roles of the objective and eyepiece lenses are reversed.

Express the magnifying power of the ″wrong end″ telescope:

$$M = -\frac{f_e}{f_o}$$

Substitute numerical values and evaluate M:

$$M = -\frac{1.50\,\text{cm}}{2.25\,\text{m}} = \boxed{-6.67\times10^{-3}}$$

General Problems

90 • To focus a camera, the distance between the lens and the image-sensing surface is varied. A wide-angle lens of a camera has a focal length of 28 mm. By how much must the lens move to change from focusing on an object at infinity to an object at a distance of 5.00 m in front of the camera?

Picture the Problem We can express the distance Δs that the lens must move as the difference between the image distances when the object is at 30 m and when it is at infinity and then express these image distances using the thin-lens equation.

Express the distance Δs that the lens must move to change from focusing on an object at infinity to one at a distance of 5 m:

$$\Delta s = s'_5 - s'_\infty$$

Solve the thin-lens equation for s' to obtain:

$$s' = \frac{fs}{s-f}$$

Substitute s'_5 and s'_∞ and simplify to obtain:

$$\Delta s = \frac{fs_5}{s_5 - f} - \frac{fs_\infty}{s_\infty - f} = \frac{fs_5}{s_5 - f} - \frac{f}{1 - f/s_\infty} = f\left[\frac{s_5}{s_5 - f} - 1\right]$$

Substitute numerical values and evaluate Δs:

$$\Delta s = (28\,\text{mm})\left[\frac{5.0\,\text{m}}{5.00\,\text{m} - 0.028\,\text{m}} - 1\right] = \boxed{0.16\,\text{mm}}$$

91 • A converging lens that has a focal length equal to 10 cm is used to obtain an image that is twice the height of the object. Find the object and image distances if (a) the image is to be upright and (b) the image is to be inverted. Draw a ray diagram for each case.

Picture the Problem We can use the thin-lens and magnification equations to obtain simultaneous equations that we can solve to find the image and object distances for the two situations described in the problem statement.

(*a*) Use the thin-lens equation to relate the image and object distances to the focal length of the lens:

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$$

Because the image is twice as large as the object:

$$m=-\frac{s'}{s}\Rightarrow s'=-2s$$

Substitute for s' to obtain:

$$\frac{1}{s}+\frac{1}{-2s}=\frac{1}{f}\Rightarrow s=\tfrac{1}{2}f$$

Substitute numerical values and evaluate s and s':

$$s=\tfrac{1}{2}(10\,\text{cm})=\boxed{5.0\,\text{cm}}$$

and

$$s'=-2(5.0\,\text{cm})=\boxed{-10\,\text{cm}}$$

(*b*) If the image is inverted, then:

$$s'=2s\ \text{ and }\ \frac{1}{s}+\frac{1}{2s}=\frac{1}{f}\Rightarrow s=\tfrac{3}{2}f$$

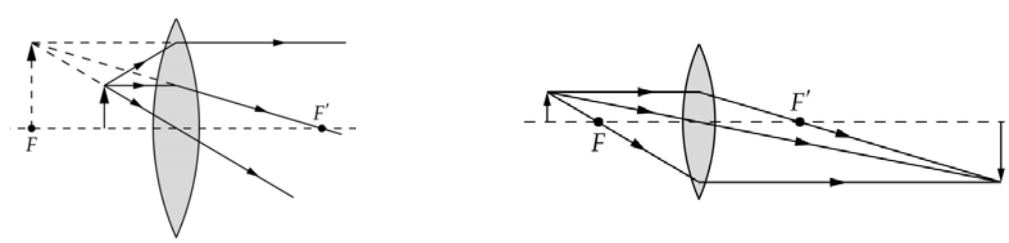
Substitute numerical values and evaluate s and s':

$$s=\tfrac{1}{2}\left[3(10\,\text{cm})\right]=\boxed{15\,\text{cm}}$$

and

$$s'=2(15\,\text{cm})=\boxed{30\,\text{cm}}$$

The ray diagrams for (*a*) (left) and (*b*) (right) follow:

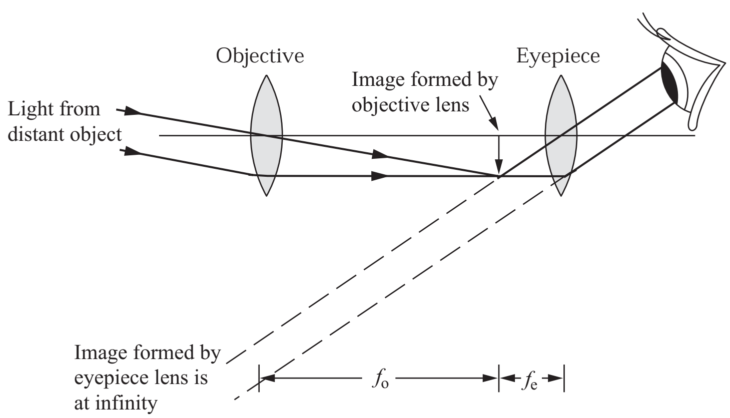


92 •• You are given two converging lenses that have focal lengths of 75 mm and 25 mm. (*a*) Show how the lenses should be arranged to form a telescope. State which lens to use as the objective, which lens to use as the eyepiece, how far apart to place the lenses and, what angular magnification you expect. (*b*) Draw a ray diagram to show how rays from a distant object are refracted by the two lenses.

Picture the Problem In an astronomical telescope the eyepiece (short focal length) and objective (long focal length) lenses are separated by the sum of their focal lengths. Given these two lenses, we'll use the 25 mm lens as the eyepiece lens and the 75 mm lens as the objective lens and mount them 100 mm apart. The angular magnification is then $M = -\frac{f_0}{f_e} = -\frac{75\,\text{mm}}{25\,\text{mm}} = -3$.

(*a*) The lens with a focal length of 75 mm should be the objective. The two lenses should be separated by 100 mm. The angular magnification is –3.

(*b*) A ray diagram showing how rays from a distant object are refracted by the two lenses follows. A real and inverted image of the distant object is formed by the objective lens near its second focal point. The eyepiece lens forms an enlarged and inverted image of the image formed by the objective lens.



93 •• [SSM] (*a*) Show how the same two lenses in Problem 92 should be arranged to form a compound microscope that has a tube length of 160 mm. State which lens to use as the objective, which lens to use as the eyepiece, how far apart to place the lenses, and what overall magnification you expect to get, assuming the user has a near point of 25 cm. (*b*) Draw a ray diagram to show how rays from a close object are refracted by the lenses.

Picture the Problem

Because the focal lengths appear in the magnification formula as a product, it would appear that it does not matter in which order we use them. The usual arrangement would be to use the shorter focal length lens as the objective but we get the same magnification in the reverse order. What difference does it make then? None in this problem. However, it is generally true that the smaller the focal length of a lens, the smaller its diameter. This condition makes it harder to use the shorter focal length lens, with its smaller diameter, as the eyepiece lens.

In a compound microscope, the lenses are separated by:

$$\delta = L + f_e + f_0$$

Substitute numerical values and evaluate δ:

$$\delta = 16\,\text{cm} + 7.5\,\text{cm} + 2.5\,\text{cm} = 26\,\text{cm}$$

The overall magnification of a compound microscope is given by:

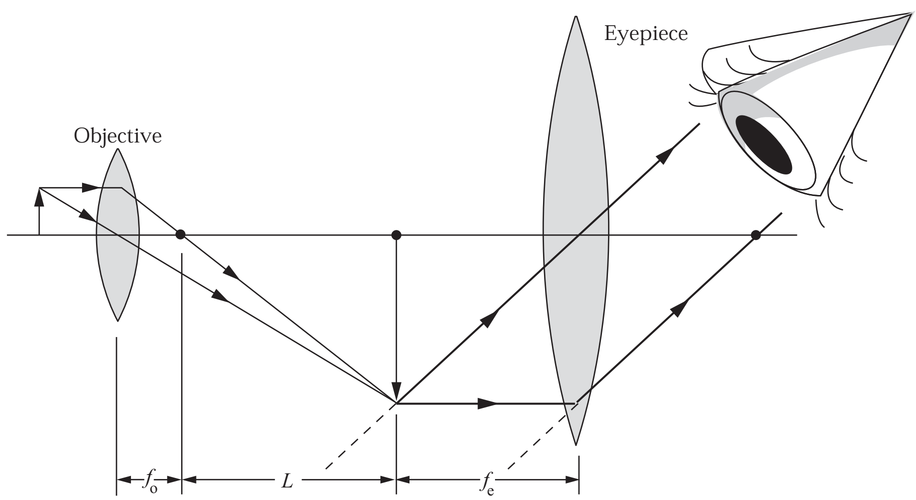
$$M = m_0 M_e = -\frac{L}{f_0}\frac{x_{np}}{f_e}$$

Substitute numerical values and evaluate M:

$$M = -\left(\frac{16\,\text{cm}}{7.5\,\text{cm}}\right)\left(\frac{25\,\text{cm}}{2.5\,\text{cm}}\right) = -21$$

The lens with a focal length of 25 mm should be the objective. The two lenses should be separated by 210 mm. The angular magnification is –21.

(*b*) A ray diagram showing how rays from a near-by object are refracted by the lenses follows. A real and inverted image of the near-by object is formed by the objective lens at the first focal point of the eyepiece lens. The eyepiece lens forms an inverted and virtual image of this image at infinity.



94 •• On a vacation, you are scuba-diving and using a diving mask that has a face plate and that bulges outward with a radius of curvature of 0.50 m. As a result, a convex spherical surface exists between the water and the air in the mask. A fish swims by you 2.5 m in front of your mask. (*a*) How far in front of the mask does the fish appear to be? (*b*) What is the lateral magnification of the image of the fish?

Picture the Problem We can use the equation for refraction at a single surface to locate the image of the fish and the expression for the magnification due to refraction at a spherical surface to find the magnification of the image.

(*a*) Use the equation describing refraction at a single surface to relate the image and object distances:

$$\frac{n_1}{s}+\frac{n_2}{s'}=\frac{n_2-n_1}{r}$$

Solving for s' yields:

$$s'=\frac{n_2 rs}{(n_2-n_1)s-n_1 r}$$

Substitute numerical values and evaluate s':

$$s'=\frac{(1)(0.50\,\text{m})(2.5\,\text{m})}{(1-1.33)(2.5\,\text{m})-(1.33)(0.50\,\text{m})}$$
$$=-0.839\,\text{m}=\boxed{-84\,\text{cm}}$$

Note that the fish appears to be only 84 cm in front of your mask.

(*b*) Express the magnification due to refraction at a spherical surface:

$$m=-\frac{n_1 s'}{n_2 s}$$

Substitute numerical values and evaluate m:

$$m=-\frac{(1.33)(-0.839\,\text{m})}{(1)(2.5\,\text{m})}=\boxed{0.45}$$

Note that the fish appears to be smaller than it actually is.

95 •• [SSM] A 35-mm digital camera has a rectangular array of CCDs (light sensors) that is 24 mm by 36 mm. It is used to take a picture of a person 175-cm tall so that the image just fills the height (24 mm) of the CCD array. How far should the person stand from the camera if the focal length of the lens is 50 mm?

Picture the Problem We can use the thin-lens equation and the definition of the magnification of an image to determine where the person should stand.

Use the thin-lens equation to relate s and s':

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$$

The magnification of the image is given by:

$$m=-\frac{s'}{s}=-\frac{2.4\,\text{cm}}{175\,\text{cm}}=-1.37\times10^{-2}$$

and

$$s'=-ms$$

Substitute for s' to obtain:

$$\frac{1}{s}-\frac{1}{ms}=\frac{1}{f}\Rightarrow s=\left(1-\frac{1}{m}\right)f$$

Substitute numerical values and evaluate s:

$$s=\left(1-\frac{1}{-1.37\times10^{-2}}\right)(50\,\text{mm})=\boxed{3.7\,\text{m}}$$

96 •• A 35-mm camera that has interchangeable lenses is used to take a picture of a hawk that has a wing span of 2.0 m. The hawk is 30 m away. What would be the ideal focal length of the lens used so that the image of the wings just fills the width of the light sensitive area of the camera, which is 36 mm?

Picture the Problem We can use the thin-lens equation and the definition of the magnification of an image to determine the ideal focal length of the lens.

Use the thin-lens equation to relate s and s':

$$\frac{1}{s}+\frac{1}{s'}=\frac{1}{f}$$

The magnification of the image is given by:

$$m=-\frac{s'}{s}=-\frac{3.6\,\text{cm}}{200\,\text{cm}}=-1.80\times10^{-2}$$

and

$$s'=-ms$$

Substitute for s' to obtain:

$$\frac{1}{s}-\frac{1}{ms}=\frac{1}{f}\Rightarrow f=\frac{s}{1-\frac{1}{m}}$$

Substitute numerical values and evaluate f:

$$f=\frac{30\,\text{m}}{1-\frac{1}{-1.80\times10^{-2}}}=\boxed{53\,\text{cm}}$$

97 •• An object is placed 12.0 cm in front of a lens that has a focal length equal to 10.0 cm. A second lens that has a focal length equal to 12.5 cm is placed 20.0 cm in back of the first lens. (*a*) Find the position of the final image. (*b*) What is the magnification of the image? (*c*) Sketch a ray diagram showing the final image.

Picture the Problem Let the numeral 1 refer to the first lens and the numeral 2 to the second lens. We apply the thin-lens equation twice; once to locate the image formed by the first lens and a second time to find the image formed by the second lens. The magnification of the image is the product of the magnifications produced by the two lenses.

(*a*) Solve the thin-lens equation for the location of the image formed by the first lens:

$$s_1' = \frac{f_1 s_1}{s_1 - f_1}$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(10\,\text{cm})(12\,\text{cm})}{12\,\text{cm} - 10\,\text{cm}} = 60\,\text{cm}$$

Because the second lens is 20 cm to the right of the first lens:

$$s_2 = 20\,\text{cm} - 60\,\text{cm} = -40\,\text{cm}$$

Solve the thin-lens equation for the location of the image formed by the second lens:

$$s_2' = \frac{f_2 s_2}{s_2 - f_2}$$

Substitute numerical values and evaluate s_2':

$$s_2' = \frac{(12.5\,\text{cm})(-40\,\text{cm})}{-40\,\text{cm} - 12.5\,\text{cm}} = \boxed{9.5\,\text{cm}}$$

i.e., the final image is 9.5 cm in back of the second lens.

(*b*) Express the magnification of the final image:

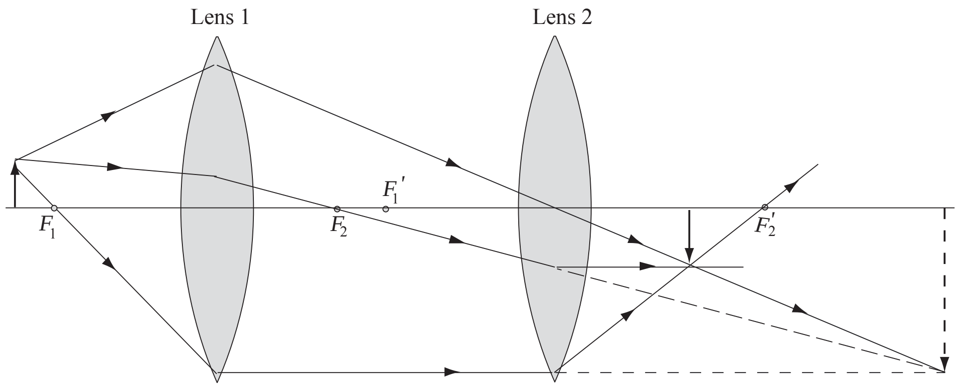
$$m = m_1 m_2 = \left(-\frac{s_1'}{s_1}\right)\left(-\frac{s_2'}{s_2}\right) = \frac{s_1' s_2'}{s_1 s_2}$$

Substitute numerical values and evaluate *m*:

$$m = \frac{(60\,\text{cm})(9.52\,\text{cm})}{(12\,\text{cm})(-40\,\text{cm})} = \boxed{-1.2}$$

i.e., the final image is about 20% larger than the object and is inverted.

(*c*) The enlarged, inverted image formed by the first lens serves as a virtual object for the second lens. The image formed from this virtual object is the real, inverted image shown in the diagram.



98 •• (*a*) Show that if f_a is the focal length of a thin lens in air, its focal length in water is given by $f_w = (n_w/n_a)(n-n_a)/(n-n_w)\,f_a$ where n_w is the index of refraction of water, n is that of the lens material and n_a is that of air.
(*b*) Calculate the focal length in air and in water of a double concave lens that has an index of refraction of 1.50 and radii of magnitude 30 cm and 35 cm.

Picture the Problem We can apply the equation for refraction at a surface to both surfaces of the lens and add the resulting equations to obtain an equation relating the image and object distances to the indices of refraction. We can then use the lens maker's equation to complete the derivation of the given relationship between f' and f.

(*a*) Relate s and s' at the water-lens interface:

$$\frac{n_w}{s}+\frac{n}{s_1'}=\frac{n-n_w}{r_1}$$

Relate s and s' at the lens-water interface:

$$\frac{n}{-s_1'}+\frac{n}{s'}=\frac{n_w-n}{r_2}$$

Add these equations to obtain:

$$n_w\left(\frac{1}{s}+\frac{1}{s'}\right)=(n-n_w)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

Let $\dfrac{1}{f_w}=\dfrac{1}{s}+\dfrac{1}{s'}$ to obtain:

$$\frac{n_w}{f_w}=(n-n_w)\left(\frac{1}{r_1}-\frac{1}{r_2}\right) \qquad (1)$$

The lens-maker's equation is:

$$\frac{1}{f_a}=\left(\frac{n}{n_a}-1\right)\left(\frac{1}{r_1}-\frac{1}{r_2}\right)$$

and

$$\frac{1}{r_1}-\frac{1}{r_2}=\frac{1}{\left(\frac{n}{n_a}-1\right)f_a}=\frac{n_a}{(n-n_a)f_a}$$

Substitute for $\frac{1}{r_1}-\frac{1}{r_2}$ in equation (1) to obtain:

$$\frac{n_w}{f_w}=(n-n_w)\left(\frac{n_a}{(n-n_a)f_a}\right)$$

Solving for f' yields:

$$f_w=\boxed{\frac{n_w(n-n_a)}{n_a(n-n_w)}f_a}$$

(*b*) Use the lens-maker's equation to find the focal length of the lens in air:

$$\frac{1}{f_a}=\left(\frac{1.50}{1.00}-1\right)\left(\frac{1}{-30\,\text{cm}}-\frac{1}{35\,\text{cm}}\right)$$

and

$$f=-32.3\,\text{cm}=\boxed{-32\,\text{cm}}$$

Use the result derived in Part (*a*) to find f_w:

$$f_w=\frac{(1.33)(1.50-1)}{1.50-1.33}(-32.3\,\text{cm})$$

$$=\boxed{-1.3\,\text{m}}$$

99 •• While parked in your car, you see a jogger in your rear view mirror, which is convex and has a radius of curvature whose magnitude is equal to 2.00 m. The jogger is 5.00 m from the mirror and is approaching at 3.50 m/s. How fast is the image of the jogger moving relative to the mirror?

Picture the Problem The speed of the jogger as seen in the mirror is $v'=ds'/dt$. We can use the mirror equation to derive an expression for v' in terms of f and ds/dt.

Solve the mirror equation for s':

$$s'=\left(\frac{1}{f}-\frac{1}{s}\right)^{-1} \qquad (1)$$

Differentiate s' with respect to time to obtain:

$$v' = \frac{ds'}{dt} = \frac{d}{dt}\left(\frac{1}{f} - \frac{1}{s}\right)^{-1} = -\left(\frac{1}{f} - \frac{1}{s}\right)^{-2}\left(\frac{1}{s^2}\right)\frac{ds}{dt}$$

Simplify this result to obtain:

$$v' = -\left(\frac{s'}{s}\right)^2 v \qquad (2)$$

Rewrite equation (1) in terms of r:

$$s' = \left(\frac{2}{r} - \frac{1}{s}\right)^{-1}$$

Find s' when $s = 5.00$ m:

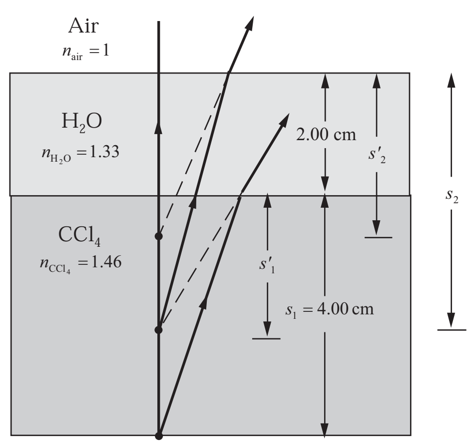
$$s' = \left(\frac{2}{-2.00\,\text{m}} - \frac{1}{5.00\,\text{m}}\right)^{-1} = -0.8333\,\text{m}$$

Use equation (2) to find $|v'|$ when $|v| = 3.50$ m/s:

$$|v'| = \left|-\left(\frac{-0.8333\,\text{m}}{5.00\,\text{m}}\right)^2(3.50\,\text{m/s})\right| = \boxed{9.72\,\text{cm/s}}$$

100 •• A 2.00-cm-thick layer of water ($n = 1.33$) floats on top of a 4.00-cm-thick layer of carbon tetrachloride ($n = 1.46$) in a tank. How far below the top surface of the water does the bottom of the tank appear, according to an observer looking down from above at normal incidence?

Picture the Problem Let the numeral 1 denote the CCl_4-H_2O interface and the numeral 2 the H_2O-air interface. We can locate the final image by applying the equation for refraction at a single surface to both interfaces. The ray diagram shown below shows a spot at the bottom of the tank and the rays of light emanating from it that form the intermediate and final images.



Use the equation for refraction at a single surface to relate s and s' at the CCl_4-H_2O interface:

$$\frac{n_{CCl_4}}{s_1}+\frac{n_{H_2O}}{s_1'}=\frac{n_{H_2O}-n_{CCl_4}}{r}$$

or, because $r = \infty$,

$$\frac{n_{CCl_4}}{s_1}+\frac{n_{H_2O}}{s_1'}=0 \Rightarrow s_1' = -\frac{n_{H_2O}s_1}{n_{CCl_4}} \quad (1)$$

Substitute numerical values and evaluate s_1':

$$s_1' = -\frac{(1.33)(4.00\text{ cm})}{1.46} = -3.64\text{ cm}$$

The depth of this image, as viewed from the H_2O-air interface is:

$$s_2 = 2.00\text{ cm} - s_1' = 2.00\text{ cm} - (-3.64\text{ cm}) = 5.64\text{ cm}$$

At the H_2O-air interface equation (1) becomes:

$$s_2' = -\frac{n_{air}s_2}{n_{H_2O}}$$

Substitute numerical values and evaluate s_2':

$$s_2' = -\frac{(1)(5.64\text{ cm})}{1.33} = -4.24\text{ cm}$$

$\boxed{\text{The apparent depth is } 4.24\text{ cm.}}$

101 ••• [SSM] An object is 15.0 cm in front of a thin converging lens that has a focal length equal to 10.0 cm. A concave mirror that has a radius equal to 10.0 cm is 25.0 cm in back of the lens. (*a*) Find the position of the final image formed by the mirror-lens combination. (*b*) Is the image real or virtual? Is the image upright or inverted? (*c*) On a diagram, show where your eye must be to see this image.

Picture the Problem We can use the thin-lens equation to locate the first image formed by the converging lens, the mirror equation to locate the image formed in the mirror, and the thin-lens equation a second time to locate the final image formed by the converging lens as the rays pass back through it.

(*a*) Solve the thin-lens equation for s_1':

$$s_1' = \frac{fs_1}{s_1 - f}$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(10.0\text{ cm})(15.0\text{ cm})}{15.0\text{ cm} - 10.0\text{ cm}} = 30\text{ cm}$$

Because the image formed by the converging lens is behind the mirror:

$$s_2 = 25\text{ cm} - 30\text{ cm} = -5\text{ cm}$$

Solve the mirror equation for s_2':

$$s_2' = \frac{fs_2}{s_2 - f}$$

Substitute numerical values and evaluate s_2':

$$s_2' = \frac{(5\,\text{cm})(-5\,\text{cm})}{-5\,\text{cm} - 5\,\text{cm}} = 2.50\,\text{cm} \text{ and the}$$

image is 22.5 cm from the lens; i.e., $s_3 = 22.5$ cm.

Solve the thin-lens equation for s_3':

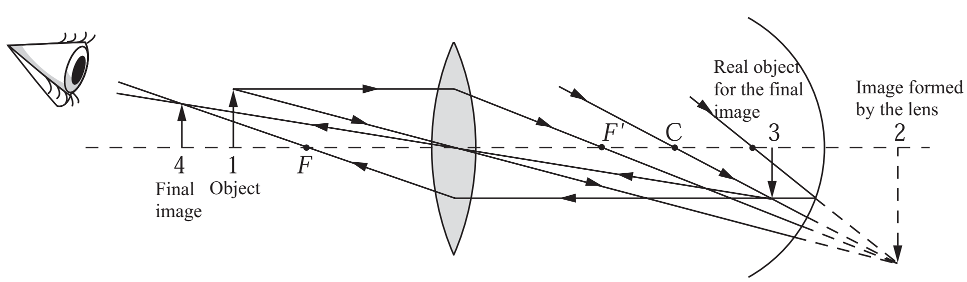
$$s_3' = \frac{fs_3}{s_3 - f}$$

Substitute numerical values and evaluate s_3':

$$s_3' = \frac{(10.0\,\text{cm})(22.5\,\text{cm})}{22.5\,\text{cm} - 10.0\,\text{cm}} = 18\,\text{cm}$$

The final position of the image is 18 cm from the lens, on the same side as the original object.

(*b*) The ray diagram is shown below. The numeral 1 represents the object. The parallel and central rays from 1 are shown; one passes through the center of the converging lens, the other is paraxial and then passes through the focal point F'. The two rays intersect behind the mirror, and the image formed there, identified by the numeral 2, serves as a virtual object for the mirror. Two rays are shown emanating from this virtual image, one through the center of the mirror, the other passing through its focal point (halfway between C and the mirror surface) and then continuing as a paraxial ray. These two rays intersect in front of the mirror, forming a real image, identified by the numeral 3. Finally, the image 3 serves as a real object for the lens; again we show two rays, a paraxial ray that then passes through the focal point F and a ray through the center of the lens. These two rays intersect to form the final $\boxed{\text{real, upright,}}$ and diminished image, identified as 4.



(*c*) To see this image the eye must be to the left of the final image.

102 ••• When a bright light source is placed 30 cm in front of a lens, there is an upright image 7.5 cm from the lens. There is also a faint inverted image 6.0 cm from the lens on the incident-light side due to reflection from the front surface of the lens. When the lens is turned around, this weaker, inverted image is 10 cm in front of the lens. Find the index of refraction of the lens.

Picture the Problem The mirror surfaces must be concave to create inverted images on reflection. Therefore, the lens is a diverging lens. Let the numeral 1 denote the lens in its initial orientation and the numeral 2 the lens in its second orientation. We can use the mirror equation to find the magnitudes of the radii of the lens' surfaces, the thin-lens equation to find its focal length, and the lens maker's equation to find its index of refraction.

Solve the mirror equation for $|r_1|$:

$$|r_1| = \frac{2s_1s_1'}{s_1' + s_1}$$

Substitute numerical values and evaluate $|r_1|$:

$$|r_1| = \frac{2(30\,\text{cm})(6.0\,\text{cm})}{6.0\,\text{cm} + 30\,\text{cm}} = 10.0\,\text{cm}$$

Solve the mirror equation for $|r_2|$:

$$|r_2| = \frac{2s_2s_2'}{s_2' + s_2}$$

Substitute numerical values and evaluate $|r_2|$:

$$|r_2| = \frac{2(30\,\text{cm})(10\,\text{cm})}{10\,\text{cm} + 30\,\text{cm}} = 15.0\,\text{cm}$$

Solve the thin-lens equation for *f*:

$$f = \frac{ss'}{s' + s}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{(30\,\text{cm})(-7.5\,\text{cm})}{-7.5\,\text{cm} + 30\,\text{cm}} = -10.0\,\text{cm}$$

Solve the lens-maker's equation for n to obtain:

$$n = \frac{n_\text{a}}{f\left(\frac{1}{r_1} - \frac{1}{r_2}\right)} + n_\text{air}$$

Because the lens is a diverging lens, $r_1 = -10$ cm and $r_2 = 15$ cm. Substitute numerical values and evaluate n:

$$n = \frac{1.00}{(-10\,\text{cm})\left(\frac{1}{-10\,\text{cm}} - \frac{1}{15\,\text{cm}}\right)} + 1.00$$

$$= \boxed{1.6}$$

103 ••• A concave mirror that has a radius of curvature equal to 50.0 cm is oriented with its axis vertical. The mirror is filled with water that has an index of refraction equal to 1.33 and a maximum depth of 1.00 cm. At what height above the vertex of the mirror must an object be placed so that its image is at the same position as the object?

Picture the Problem Assume that the object is very small compared to r so that all incident and reflected rays traverse 1 cm of water. The problem involves two refractions at the air–water interface and one reflection at the mirror. Let the numeral 1 refer to the first refraction at the air–water interface, the numeral 2 to the reflection in the mirror surface, and the numeral 3 to the second refraction at the water–air interface.

Use the equation for refraction at a single surface to relate s_1 and s_1':

$$\frac{n_1}{s_1}+\frac{n_2}{s_1'}=\frac{n_2-n_1}{r}$$

or, because $r=\infty$,

$$\frac{n_1}{s_1}+\frac{n_2}{s_1'}=0\Rightarrow s_1'=-\frac{n_2 s_1}{n_1}$$

Let $n_2 = n$. Because $n_1 = 1$:

$$s_1'=-ns_1$$

Find the object distance for the mirror:

$$s_2=1-s_1'=1+ns_1$$

where 1 has units of cm.

Solve the mirror equation for s_2':

$$s_2'=\left(\frac{2}{r}-\frac{1}{s_2}\right)^{-1}$$

Substitute for s_2:

$$s_2'=\left(\frac{2}{r}-\frac{1}{1+ns_1}\right)^{-1}$$

Find the object distance s_3 for the water–air interface:

$$s_3=1-s_2'=1-\left(\frac{2}{r}-\frac{1}{1+ns_1}\right)^{-1}$$

Use the equation for refraction at a single surface to relate s_3 and s_3':

$$\frac{n_1}{s_3}+\frac{n_2}{s_3'}=\frac{n_2-n_1}{r}$$

or, because $r=\infty$,

$$\frac{n_1}{s_3}+\frac{n_2}{s_3'}=0\Rightarrow s_3'=-\frac{n_2 s_3}{n_1}$$

Because $n_2 = 1$ and $n_1 = n$:

$$s_3{}' = -\frac{s_3}{n} = -\frac{1-\left(\frac{2}{r}-\frac{1}{1+ns_1}\right)^{-1}}{n}$$

Equate $s_3{}'$ and s_1:

$$s_1 = -\frac{1-\left(\frac{2}{r}-\frac{1}{1+ns_1}\right)^{-1}}{n}$$

Simplifying yields:

$$s_1^2 + \frac{2-r}{n}s_1 + \frac{1-r}{n^2} = 0$$

Substitute numerical values and simplify:

$$s_1^2 + \frac{2.00\,\text{cm} - 50.0\,\text{cm}}{1.33}s_1 + \frac{1.00\,\text{cm} - 50.0\,\text{cm}}{(1.33)^2} = 0$$

or

$$s_1^2 - 36.09s_1 - 27.70 = 0$$

where s_1 is in cm.

Solve for the positive value of s_1 to obtain:

$$s_1 = \boxed{37\,\text{cm}}$$

104 ••• A concave side of a lens has a radius of curvature of magnitude equal to 17.0 cm, and the convex side of the lens that has a radius of curvature of magnitude equal to 8.00 cm. The focal length of the lens in air is 27.5 cm. When the lens is placed in a liquid that has an unknown index of refraction, the focal length increases to 109 cm. What is the index of refraction of the liquid?

Picture the Problem We can use the lens maker's equation, in conjunction with the result given in Problem 108, to find the index of refraction of the liquid.

Solve the lens-maker's equation for n:

$$n = \frac{n_{\text{air}}}{f\left(\frac{1}{r_1}-\frac{1}{r_2}\right)} + n_{\text{air}}$$

Substitute numerical values and evaluate n:

$$n = \frac{1.00}{(27.5\,\text{cm})\left(\frac{1}{-17.0\,\text{cm}} - \frac{1}{-8.00\,\text{cm}}\right)} + 1.00 = 1.55$$

From Problem 98, the focal length of the lens in the liquid, f_L, is related to the focal length of the lens in air, f, according to:

$$f_L = \frac{n_L(n - n_{air})}{n_{air}(n - n_L)} f$$

Solving for n_L yields:

$$n_L = \frac{n_{air} n f_L}{(n - n_{air}) f + n_{air} f_L}$$

Substitute numerical values and evaluate n_L:

$$n_L = \frac{(1.55)(1.00)(109\,\text{cm})}{(1.55 - 1.00)(27.5\,\text{cm}) + (1.00)(109\,\text{cm})} = \boxed{1.4}$$

105 ••• A solid glass ball of radius 10.0 cm has an index of refraction equal to 1.500. The right half of the ball is silvered so that it acts as a concave mirror (Figure 32-63). Find the position of the final image formed for an object located at (*a*) 40.0 cm, and (*b*) 30.0 cm to the left of the center of the ball.

Picture the Problem The problem involves two refractions and one reflection. We can use the refraction at spherical surface equation and the mirror equation to find the images formed in the two refractions and one reflection. Let the numeral 1 refer to the first refraction at the air-glass interface, the numeral 2 to the reflection from the silvered surface, and the numeral 3 refer to the refraction at the glass-air interface.

(*a*) The image and object distances for the refraction at the surface of the ball are related according to:

$$\frac{n_1}{s_1} + \frac{n_2}{s_1'} = \frac{n_2 - n_1}{r}$$

Solve for s_1' to obtain:

$$s_1' = \frac{n_2 r s_1}{(n_2 - n_1)s_1 - n_1 r}$$

Substitute numerical values and evaluate s_1':

$$s_1' = \frac{(1.500)(10.0\,\text{cm})(30.0\,\text{cm})}{(1.500 - 1)(30.0\,\text{cm}) - (1)(10.0\,\text{cm})} = 90.0\,\text{cm}$$

The object for the mirror surface is behind the mirror and its distance from the surface of the mirror is:

$$s_2 = 20.0\,\text{cm} - 90.0\,\text{cm} = -70.0\,\text{cm}$$

Use the mirror equation to relate s_2 and s_2':

$$\frac{1}{s_2}+\frac{1}{s_2'}=\frac{2}{r}\Rightarrow s_2'=\frac{rs_2}{2s_2-r}$$

Substitute numerical values and evaluate s_2':

$$s_2'=\frac{(10.0\,\text{cm})(-70.0\,\text{cm})}{2(-70.0\,\text{cm})-10.0\,\text{cm}}=4.67\,\text{cm}$$

The object for the second refraction at the glass-air interface is in front of the mirrored surface and its distance from the glass-air interface is:

$$s_3=20.0\,\text{cm}-4.67\,\text{cm}=15.3\,\text{cm}$$

The image and object distances for the second refraction are related according to:

$$\frac{n_1}{s_3}+\frac{n_2}{s_3'}=\frac{n_2-n_1}{r}$$

Solve for s_3' to obtain:

$$s_3'=\frac{n_2rs_3}{(n_2-n_1)s_3-n_1r}$$

Noting that $r=-10.0$ cm, substitute numerical values and evaluate s_3':

$$s_3'=\frac{(1)(-10.0\,\text{cm})(15.3\,\text{cm})}{(1.500-1)(15.3\,\text{cm})-(1.500)(-10.0\,\text{cm})}=-6.76\,\text{cm}$$

The final image is 3.2 cm to the left of the center of the ball.

(*b*) With $s_1 = 20.0$ cm:

$$s_1'=\frac{(1.500)(10.0\,\text{cm})(20.0\,\text{cm})}{(1.500-1)(20.0\,\text{cm})-(1)(10.0\,\text{cm})}$$
$$=\text{undefined}$$

Because s_1' is undefined, no image is formed when the object is 20.0 cm to the left of the glass ball. (Alternatively, an image is formed an infinite distance to the left of the ball.)

106 ••• (*a*) Show that a small change dn in the index of refraction of a lens material produces a small change in the focal length df given approximately by $df/f=-dn/(n-n_{\text{air}})$. (*b*) Use this result to estimate the focal length of a thin lens for blue light, for which $n = 1.530$, if the focal length for red light, for which $n = 1.470$, is 20.0 cm.

Picture the Problem We can solve the lens maker's equation for f and then differentiate with respect to n and simplify to obtain $df/f=-dn/(n-n_{\text{air}})$.

(*a*) The lens maker's equation is:

$$\frac{1}{f}=\left(\frac{n}{n_{\text{air}}}-1\right)\left(\frac{1}{r_1}-\frac{1}{r_2}\right) \qquad (1)$$

Differentiating both sides gives:

$$-\frac{df}{f^2}=\frac{dn}{n_{\text{air}}}\left(\frac{1}{r_1}-\frac{1}{r_2}\right) \qquad (2)$$

Diving equation (2) by equation (1) and simplifying yields:

$$\frac{-\dfrac{df}{f^2}}{\dfrac{1}{f}}=\frac{\dfrac{dn}{n_{\text{air}}}\left(\dfrac{1}{r_1}-\dfrac{1}{r_2}\right)}{\left(\dfrac{n}{n_{\text{air}}}-1\right)\left(\dfrac{1}{r_1}-\dfrac{1}{r_2}\right)}=\frac{\dfrac{dn}{n_{\text{air}}}}{\dfrac{n}{n_{\text{air}}}-1}=\frac{\dfrac{dn}{n_{\text{air}}}}{\dfrac{n-n_{\text{air}}}{n_{\text{air}}}}$$

Simplifying both sides yields:

$$\frac{df}{f}=\boxed{-\frac{dn}{n-n_{\text{air}}}}$$

(*b*) Express the focal length for blue light in terms of the focal length for red light:

$$f_{\text{blue}}=f_{\text{red}}+\Delta f \qquad (1)$$

Approximate *df*/*f* by $\Delta f/f$ and *dn* by Δn to obtain:

$$\frac{\Delta f}{f}\approx -\frac{\Delta n}{n-n_{\text{air}}}$$

Solving for Δf yields :

$$\Delta f=-\frac{f\,\Delta n}{n-n_{\text{air}}}$$

Substitute for Δf in equation (1) to obtain:

$$f_{\text{blue}}=f_{\text{red}}-\frac{f_{\text{red}}\Delta n}{n-n_{\text{air}}}$$

$$=f_{\text{red}}\left(1-\frac{\Delta n}{n_{\text{red}}-n_{\text{air}}}\right)$$

Substitute numerical values and evaluate f_{blue}:

$$f_{\text{blue}}=(20.0\,\text{cm})\left(1-\frac{1.530-1.470}{1.470-1.00}\right)=\boxed{17\,\text{cm}}$$

107 ••• **[SSM]** The lateral magnification of a spherical mirror or a thin lens is given by $m = -s'/s$. Show that for objects of small horizontal extent, the longitudinal magnification is approximately $-m^2$. *Hint:* Show that $ds'/ds = -s'^2/s^2$.

Picture the Problem Examine the amount by which the image distance s' changes due to a change in s.

Solve the thin-lens equation for s':

$$s' = \left(\frac{1}{f} - \frac{1}{s}\right)^{-1}$$

Differentiate s' with respect to s:

$$\frac{ds'}{ds} = \frac{d}{ds}\left[\left(\frac{1}{f} - \frac{1}{s}\right)^{-1}\right] = -\frac{1}{\left(\frac{1}{f} - \frac{1}{s}\right)^2}\frac{1}{s^2} = -\frac{s'^2}{s^2} = -m^2$$

$$\boxed{\text{The image of an object of length } \Delta s \text{ will have a length } -m^2\Delta s.}$$

Chapter 33
Interference and Diffraction

Conceptual Problems

1 • A phase difference due to path-length difference is observed for monochromatic visible light. Which phase difference requires the least (minimum) path length difference? (*a*) 90° (*b*) 180° (*c*) 270° (*d*) the answer depends on the wavelength of the light.

Determine the Concept The phase difference δ due to a path difference Δr are related according to $\delta/2\pi = \Delta r/\lambda$. Therefore, the least path length difference corresponds to the smallest phase difference. $\boxed{(a)}$ is correct.

2 • Which of the following pairs of light sources are coherent: (*a*) two candles, (*b*) one point source and its image in a plane mirror, (*c*) two pinholes uniformly illuminated by the same point source, (*d*) two headlights of a car, (*e*) two images of a point source due to reflection from the front and back surfaces of a soap film.

Determine the Concept Coherent sources have a constant phase difference. The pairs of light sources that satisfy this criterion are (*b*), (*c*), and (*e*).

3 • **[SSM]** The spacing between Newton's rings decreases rapidly as the diameter of the rings increases. Explain qualitatively why this occurs.

Determine the Concept The thickness of the air space between the flat glass and the lens is approximately proportional to the square of *d*, the diameter of the ring. Consequently, the separation between adjacent rings is proportional to 1/*d*.

4 • If the angle of a wedge-shaped air film, such as that in Example 32-2 is too large, fringes are not observed. Why?

Determine the Concept There are two possible reasons that fringes might not be observed. (1) The distance between adjacent fringes is so small that the fringes are not resolved by the eye. (2) Twice the thickness of the air space is greater than the coherence length of the light. If this is the case, fringes would be observed in the region close to the point where the thickness of the air space approaches zero.

5 • Why must a film that is used to observe interference colors be thin?

Determine the Concept Colors are observed when the light reflected off the front and back surfaces of the film interfere destructively for some wavelengths and

constructively for other wavelengths. For this interference to occur, the phase difference between the light reflected off the front and back surfaces of the film must be constant. This means that twice the thickness of the film must be less than the coherence length of the light. The film is called a thin film if twice its thickness is less than the coherence length of the light.

6 • A loop of wire is dipped in soapy water and held up so that the soap film is vertical. (*a*) Viewed by reflection with white light, the top of the film appears black. Explain why. (*b*) Below the black region are colored bands. Is the first band red or violet?

(*a*) The phase change due to reflection from the front surface of the film is 180°; the phase change due to reflection from the back surface of the film is 0°. As the film thins toward the top, the phase change due to the path length difference between the two reflected waves (the phase difference associated with the film's thickness) becomes negligible and the two reflected waves interfere destructively.

(*b*) The first constructive interference will arise when twice the thickness of the film is equal to half the wavelength of the color with the shortest wavelength. Therefore, the first band will be violet (shortest visible wavelength).

7 • **[SSM]** A two-slit interference pattern is formed using monochromatic laser light with a wavelength of 640 nm. At the second maximum from the central maximum, what is the path-length difference between the light coming from each of the slits? (*a*) 640 nm (*b*) 320 nm (*c*) 960 nm (*d*) 1280 nm.

Determine the Concept For constructive interference, the path difference is an integer multiple of λ; that is, $\Delta r = m\lambda$. For $m = 2$, $\Delta r = 2(640\text{ nm})$. $\boxed{(d)}$ is correct.

8 • A two-slit interference pattern is formed using monochromatic laser light with a wavelength of 640 nm. At the first minimum from the central maximum, what is the path-length difference between the light coming from each of the slits? (*a*) 640 nm (*b*) 320 nm (*c*) 960 nm (*d*) 1280 nm.

Determine the Concept For destructive interference, the path difference is an odd-integer multiple of $\frac{1}{2}\lambda$; that is $\Delta r = m\left(\frac{1}{2}\lambda\right), m = 1, 3, 5, \ldots$. For the first minimum, $m = 1$ and $\Delta r = \frac{1}{2}(640\text{ nm}) = 320\text{ nm}$. $\boxed{(b)}$ is correct.

9 • A two-slit interference pattern is formed using monochromatic laser light with a wavelength of 450 nm. What happens to the distance between the first maximum and the central maximum as the two slits are moved closer together? (*a*) The distance increases. (*b*) The distance decreases. (*c*) The distance remains the same.

Determine the Concept The relationship between the slit separation d and the angular position θ_m of each maximum is given by $d\sin\theta_m = m\lambda, m = 0,1,2,...$ (Equation 33-2). Because d and $\sin\theta_m$ are inversely proportional for a given wavelength and interference maximum (value of m), decreasing d increases $\sin\theta_m$ and θ_m. $\boxed{(a)}$ is correct.

10 • A two-slit interference pattern is formed using two different monochromatic lasers, one green and one red. Which color light has its first maximum closer to the central maximum? (*a*) Green, (*b*) red, (*c*) both maxima are in the same location.

Determine the Concept The relationship between the slit separation d, the angular position θ_m of each maximum, and the wavelength of the light illuminating the slits is given by $d\sin\theta_m = m\lambda,\ m = 0,1,2,...$ (Equation 33-2). Because λ and $\sin\theta_m$ are directly proportional for a given interference maximum (value of m) and the wavelength of green light is shorter than the wavelength of red light, $\boxed{(a)}$ is correct.

11 • A single slit diffraction pattern is formed using monochromatic laser light with a wavelength of 450 nm. What happens to the distance between the first maximum and the central maximum as the slit is made narrower? (*a*) The distance increases. (*b*) The distance decreases. (*c*) The distance remains the same.

Determine the Concept The relationship between the slit width a, the angular position θ_m of each maximum, and the wavelength of the light illuminating the slit is given by $a\sin\theta_m = m\lambda,\ m = 1,2,3,...$ (Equation 33-11). Because a and $\sin\theta_m$ are inversely proportional for a given diffraction maximum (value of m), narrowing the slit increases $\sin\theta_m$ and θ_m. $\boxed{(a)}$ is correct.

12 • Equation 33-2 which is $d \sin \theta_\mathrm{m} = m\lambda$, and Equation 33-11, which is $a \sin \theta_\mathrm{m} = m\lambda$, are sometimes confused. For each equation, define the symbols and explain the equation's application.

Determine the Concept Equation 33-2 expresses the condition for an intensity maximum in two-slit interference. Here d is the slit separation, λ the wavelength of the light, m an integer, and θ_m the angle at which the interference maximum appears. Equation 33-11 expresses the condition for an intensity minimum in single-slit diffraction. Here a is the width of the slit, λ the wavelength of the light, and θ_m the angle at which the minimum appears, and m is a nonzero integer.

13 • When a diffraction grating is illuminated by white light, the first-order maximum of green light (*a*) is closer to the central maximum than the first-order maximum of red light. (*b*) is closer to the central maximum than the first-order maximum of blue light. (*c*) overlaps the second-order maximum of red light. (*d*) overlaps the second-order maximum of blue light.

Picture the Problem We can solve $d\sin\theta = m\lambda$ for θ with $m = 1$ to express the location of the first-order maximum as a function of the wavelength of the light.

The interference maxima in a diffraction pattern are at angles θ given by:

$$d\sin\theta = m\lambda$$

where d is the separation of the slits and $m = 0, 1, 2, \ldots$

Solve for the angular location θ_1 of the first-order maximum :

$$\theta_1 = \sin^{-1}\left(\frac{\lambda}{d}\right)$$

Because $\lambda_{\text{green light}} < \lambda_{\text{red light}}$:

$\theta_{\text{green light}} < \theta_{\text{red light}}$ and $\boxed{(a)}$ is correct.

14 • A double-slit interference experiment is set up in a chamber that can be evacuated. Using light from a helium-neon laser, an interference pattern is observed when the chamber is open to air. As the chamber is evacuated, one will note that (*a*) the interference fringes remain fixed. (*b*) the interference fringes move closer together. (*c*) the interference fringes move farther apart. (*d*) the interference fringes disappear completely.

Determine the Concept

The distance on the screen to *m*th bright fringe is given by:

$$y_m = m\frac{\lambda_n L}{d}$$

where L is the distance from the slits to the screen, λ_n is the wavelength of the light in a medium whose index of refraction is n, and d is the separation of the slits.

The separation of the interference fringes is given by:

$$y_{m+1} - y_m = (m+1)\frac{\lambda_n L}{d} - m\frac{\lambda_n L}{d} = \frac{\lambda_n L}{d}$$

Because the index of refraction of a vacuum is slightly less than the index of refraction of air, the removal of air increases λ_n and, hence, $y_m - y_{m-1}$. $\boxed{(c)}$ is correct.

15 • **[SSM]** True or false:

(*a*) When waves interfere destructively, the energy is converted into heat energy.
(*b*) Interference patterns are observed only if the relative phases of the waves that superimpose remain constant.
(*c*) In the Fraunhofer diffraction pattern for a single slit, the narrower the slit, the wider the central maximum of the diffraction pattern.
(*d*) A circular aperture can produce both a Fraunhofer diffraction pattern and a Fresnel diffraction pattern.
(*e*) The ability to resolve two point sources depends on the wavelength of the light.

(*a*) False. When destructive interference of light waves occurs, the energy is no longer distributed evenly. For example, light from a two-slit device forms a pattern with very bright and very dark parts. There is practically no energy at the dark fringes and a great deal of energy at the bright fringe. The total energy over the entire pattern equals the energy from one slit plus the energy from the second slit. Interference re-distributes the energy.

(*b*) True.

(*c*) True. The width of the central maximum in the diffraction pattern is given by $\theta_m = \sin^{-1}\frac{m\lambda}{a}$ where *a* is the width of the slit. Hence, the narrower the slit, the wider the central maximum of the diffraction pattern.

(*d*) True.

(*e*) True. The critical angle for the resolution of two sources is directly proportional to the wavelength of the light emitted by the sources ($\alpha_c = 1.22\frac{\lambda}{D}$).

16 • You observe two very closely-spaced sources of white light through a circular opening using various filters. Which color filter is most likely to prevent your resolving the images on your retinas as coming from two distinct sources? (*a*) red (*b*) yellow (*c*) green (*d*) blue (*e*) The filter choice is irrelevant.

Determine the Concept The condition for the resolution of the two sources is given by Rayleigh's criterion: $\alpha_c = 1.22\lambda/D$ (Equation 33-25), where α_c is the critical angular separation and D is the diameter of the aperture. The larger the critical angle required for resolution, the less likely it is that you can resolve the sources as being two distinct sources. Because α_c and λ are directly proportional, the filter that passes the shorter wavelength light would be most likely to resolve the sources and the longer wavelength (red) would be most likely to prevent resolving the sources. $\boxed{(a)}$ is correct.

17 •• Explain why the ability to distinguish the two headlights of an oncoming car, at a given distance, is easier for the human eye at night than during daylight hours. Assume the headlights of the oncoming car are on during both daytime and nighttime hours.

Determine the Concept The condition for the resolution of the two sources is given by Rayleigh's criterion: $\alpha_c = 1.22\lambda/D$ (Equation 33-25), where α_c is the critical angular separation, D is the diameter of the aperture, and λ is the wavelength of the light coming from the objects, in this case headlights, to be resolved. Because the diameter of the pupils of your eyes are larger at night, the critical angle is smaller at night, which means that at night you can resolve the light as coming from two distinct sources when they are at a greater distance.

Estimation and Approximation

18 • It is claimed that the Great Wall of China is the only man made object that can be seen from space with the naked eye. Check to see if this claim is true, based on the resolving power of the human eye. Assume the observers are in low-Earth orbit that has an altitude of about 250 km.

Picture the Problem We'll assume that the diameter of the pupil of the eye is 5.0 mm and use the best-case scenario (the minimum resolvable width varies directly with the wavelength of the light reflecting from the object) that the wavelength of light is 400 nm (the lower limit for the human eye). Then we can use the expression for the minimum angular separation of two objects than can be resolved by the eye and the relationship between this angle and the width of an object and the distance from which it is viewed to support the claim.

Relate the width w of an object that can be seen at an altitude h to the critical angular separation α_c:

$$\tan\alpha_c = \frac{w}{h} \Rightarrow w = h\tan\alpha_c$$

The minimum angular separation α_c of two point objects that can just be resolved by an eye depends on the diameter D of the eye and the wavelength λ of light:

$$\alpha_c = 1.22\frac{\lambda}{D}$$

Substitute for α_c in the expression for w to obtain:

$$w = h\tan\left(1.22\frac{\lambda}{D}\right)$$

Substitute numerical values and evaluate w_{min} for an altitude of 250 km:

$$w_{min} = (250\,\text{km})\tan\left(1.22\left(\frac{400\,\text{nm}}{5.0\,\text{mm}}\right)\right) \approx 24\,\text{m}$$

This claim is probably false. Because the minimum width that is resolvable from low-Earth orbit (250 km) is 24 m and the width of the Great Wall is 5 to 8 m high and 5 m wide, so this claim is likely false. However, it is easily seen using binoculars, and pictures can be taken of it using a camera. This is because both binoculars and cameras have apertures that are larger than the pupil of the human eye. (The Chinese astronaut Yang Liwei reported that he was not able to see the wall with the naked eye during the first Chinese manned space flight in 2003.)

19 •• [SSM] (*a*) Estimate how close an approaching car at night on a flat, straight stretch of highway must be before its headlights can be distinguished from the single headlight of a motorcycle. (*b*) Estimate how far ahead of you a car is if its two red taillights merge to look as if they were one.

Picture the Problem Assume a separation of 1.5 m between typical automobile headlights and tail lights, a nighttime pupil diameter of 5.0 mm, 550 nm for the wavelength of the light (as an average) emitted by the headlights, 640 nm for red taillights, and apply the Rayleigh criterion.

(*a*) The Rayleigh criterion is given by Equation 33-25:

$$\alpha_c = 1.22\frac{\lambda}{D}$$

where D is the separation of the headlights (or tail lights).

The critical angular separation is also given by:

$$\alpha = \frac{d}{L}$$

where d is the separation of head lights (or tail lights) and L is the distance to approaching or receding automobile.

Equate these expressions for α_c to obtain:

$$\frac{d}{L} = 1.22\frac{\lambda}{D} \Rightarrow L = \frac{Dd}{1.22\lambda}$$

Substitute numerical values and evaluate L:

$$L = \frac{(5.0\,\text{mm})(1.5\,\text{m})}{1.22(550\,\text{nm})} \approx \boxed{11\,\text{km}}$$

(b) For red light:

$$L = \frac{(5.0\,\text{mm})(1.5\,\text{m})}{1.22(640\,\text{nm})} \approx \boxed{9.6\,\text{km}}$$

20 •• A small loudspeaker is located at a large distance to the east from you. The loudspeaker is driven by a sinusoidal current whose frequency can be varied. Estimate the lowest frequency for which your ears would receive the sound waves exactly out of phase when you are facing north.

Picture the Problem If your ears receive the sound exactly out of phase, the waves arriving at your ear that is farthest from the speaker must be traveling one-half wavelength farther than the waves arriving at your ear that is nearest the speaker. The lowest frequency corresponds to the longest wavelength. Assume that the speaker and your ears are on the same line and let the distance between your ears be about 20 cm. Take the speed of sound in air to be 343 m/s.

The frequency received by your ears is given by:

$$f = \frac{v}{\lambda}$$

Let Δr be the distance between your ears (the path difference) to obtain:

$$\Delta r = \tfrac{1}{2}\lambda \Rightarrow \lambda = 2\Delta r$$

Substituting for λ yields:

$$f = \frac{v}{2\Delta r}$$

Substitute numerical values and evaluate f:

$$f = \frac{343\,\text{m/s}}{2(20\,\text{cm})} = 0.86\,\text{kHz}$$

or between 0.80 and 0.90 kHz.

21 •• **[SSM]** Estimate the maximum distance a binary star system could be resolvable by the human eye. Assume the two stars are about fifty times further apart than Earth and Sun are. Neglect atmospheric effects. (A test similar to this ″eye test″ was used in ancient Rome to test for eyesight acuity before entering the army. A normal eye could just barely resolve two well-known close-together stars in the sky. Anyone who could not tell there were two stars was rejected. In this case, the stars were not a binary system, but the principle is the same.)

Picture the Problem Assume that the diameter of a pupil at night is 5.0 mm and that the wavelength of light is in the middle of the visible spectrum at about 550 nm. We can use the Rayleigh criterion for the separation of two sources and the geometry of the Earth-binary star system to derive an expression for the distance to the binary stars.

If the distance between the binary stars is represented by *d* and the Earth-star distance by *L*, then their angular separation is given by:

$$\alpha = \frac{d}{L}$$

The critical angular separation of the two sources is given by the Rayleigh criterion:

$$\alpha_c = 1.22\frac{\lambda}{D}$$

For $\alpha = \alpha_c$:

$$\frac{d}{L} = 1.22\frac{\lambda}{D} \Rightarrow L = \frac{Dd}{1.22\lambda}$$

Substitute numerical values and evaluate *L*:

$$L = \frac{(5.0\text{ mm})(50)(1.5\times10^{11}\text{ m})}{1.22(550\text{ nm})}$$

$$\approx 5.59\times10^{13}\text{ km}\times\frac{1\,c\cdot\text{y}}{9.461\times10^{15}\text{ m}}$$

$$\boxed{5.9\,c\cdot\text{y}}$$

Phase Difference and Coherence

22 • Light of wavelength 500 nm is incident normally on a film of water 1.00 μm thick. (*a*) What is the wavelength of the light in the water? (*b*) How many wavelengths are contained in the distance 2*t*, where *t* is the thickness of the film? (*c*) What is the phase difference between the wave reflected from the top of the air–water interface and the wave reflected from the bottom of the water–air interface in the region where the two reflected waves superpose?

Picture the Problem The wavelength of light in a medium whose index of refraction is *n* is the ratio of the wavelength of the light in air divided by *n*. The number of wavelengths of light contained in a given distance is the ratio of the distance to the wavelength of light in the given medium. The difference in phase between the two waves is the sum of a π phase shift in the reflected wave and a phase shift due to the additional distance traveled by the wave reflected from the bottom of the water–air interface.

(*a*) Express the wavelength of light in water in terms of the wavelength of light in air:

$$\lambda_{\text{water}} = \frac{\lambda_{\text{air}}}{n_{\text{water}}} = \frac{500\,\text{nm}}{1.33} = \boxed{376\,\text{nm}}$$

(*b*) Relate the number of wavelengths *N* to the thickness *t* of the film and the wavelength of light in water:

$$N=\frac{2t}{\lambda_{\text{water}}}=\frac{2(1.00\ \mu\text{m})}{376\,\text{nm}}=\boxed{5.32}$$

(*c*) Express the phase difference as the sum of the phase shift due to reflection and the phase shift due to the additional distance traveled by the wave reflected from the bottom of the water–air interface:

$$\delta=\delta_{\text{reflection}}+\delta_{\text{additional distance traveled}}$$
$$=\pi+\frac{2t}{\lambda_{\text{water}}}2\pi=\pi+2\pi N$$

Substitute for *N* and evaluate δ:

$$\delta=\pi\,\text{rad}+2\pi(5.32\,\text{rad})=11.64\pi\,\text{rad}$$
$$=\boxed{11.6\pi\,\text{rad}}$$

or, subtracting 11.64π rad from 12π rad,

$$\delta=0.4\pi\,\text{rad}=\boxed{1.1\ \text{rad}}$$

23 •• [SSM] Two coherent microwave sources both produce waves of wavelength 1.50 cm. The sources are located in the $z = 0$ plane, one at $x = 0$, $y = 15.0$ cm and the other at $x = 3.00$ cm, $y = 14.0$ cm. If the sources are in phase, find the difference in phase between these two waves for a receiver located at the origin.

Picture the Problem The difference in phase depends on the path difference according to $\delta=\frac{\Delta r}{\lambda}2\pi$. The path difference is the difference in the distances of (0, 15.0 cm) and (3.00 cm, 14.0 cm) from the origin.

Relate a path difference Δr to a phase shift δ:

$$\delta=\frac{\Delta r}{\lambda}2\pi$$

The path difference Δr is:

$$\Delta r=15.0\,\text{cm}-\sqrt{(3.00\,\text{cm})^2+(14.0\,\text{cm})^2}$$
$$=0.682\,\text{cm}$$

Substitute numerical values and evaluate δ:

$$\delta=\left(\frac{0.682\,\text{cm}}{1.50\,\text{cm}}\right)2\pi\approx\boxed{2.9\,\text{rad}}$$

Interference in Thin Films

24 • A wedge-shaped film of air is made by placing a small slip of paper between the edges of two flat plates of glass. Light of wavelength 700 nm is

incident normally on the glass plates, and interference fringes are observed by reflection. (*a*) Is the first fringe near the point of contact of the plates dark or bright? Why? (*b*) If there are five dark fringes per centimeter, what is the angle of the wedge?

Picture the Problem Because the *m*th fringe occurs when the path difference 2*t* equals *m* wavelengths, we can express the additional distance traveled by the light in air as an $m\lambda$. The thickness of the wedge, in turn, is related to the angle of the wedge and the distance from its vertex to the *m*th fringe.

(*a*) The first fringe is dark because the phase difference due to reflection by the bottom surface of the top plate and the top surface of the bottom plate is 180°

(*b*) The *m*th fringe occurs when the path difference 2*t* equals *m* wavelengths:

$$2t = m\lambda$$

Relate the thickness of the air wedge to the angle of the wedge:

$$\theta = \frac{t}{x} \Rightarrow t = x\theta$$

where we've used a small-angle approximation to replace an arc length by the length of a chord.

Substitute for *t* to obtain:

$$2x\theta = m\lambda \Rightarrow \theta = \frac{m\lambda}{2x} = \frac{1}{2}\frac{m}{x}\lambda$$

Substitute numerical values and evaluate θ:

$$\theta = \frac{1}{2}\left(\frac{5}{\text{cm}}\right)(700\,\text{nm}) = \boxed{1.75\times10^{-4}\text{ rad}}$$

25 •• [SSM] The diameters of fine fibers can be accurately measured using interference patterns. Two optically flat pieces of glass of length *L* are arranged with the wire between them, as shown in Figure 33-40. The setup is illuminated by monochromatic light, and the resulting interference fringes are observed. Suppose that *L* is 20.0 cm and that yellow sodium light (wavelength of 590 nm) is used for illumination. If 19 bright fringes are seen along this 20.0-cm distance, what are the limits on the diameter of the wire? *Hint: The nineteenth fringe might not be right at the end, but you do not see a twentieth fringe at all.*

Picture the Problem The condition that one sees *m* fringes requires that the path difference between light reflected from the bottom surface of the top slide and the top surface of the bottom slide is an integer multiple of a wavelength of the light.

The *m*th fringe occurs when the path difference 2*d* equals *m* wavelengths:

$$2d = m\lambda \Rightarrow d = \frac{m\lambda}{2}$$

Because the nineteenth (but not the twentieth) bright fringe can be seen, the limits on *d* must be:

$$\left(m - \tfrac{1}{2}\right)\frac{\lambda}{2} < d < \left(m + \tfrac{1}{2}\right)\frac{\lambda}{2}$$

where $m = 19$

Substitute numerical values to obtain:

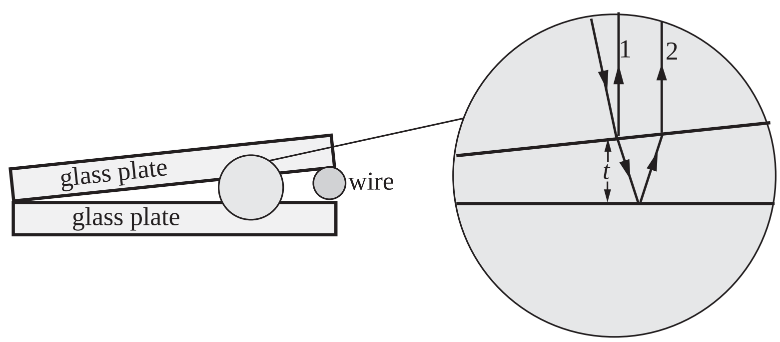
$$\left(19 - \tfrac{1}{2}\right)\frac{590\,\text{nm}}{2} < d < \left(19 + \tfrac{1}{2}\right)\frac{590\,\text{nm}}{2}$$

or

$$\boxed{5.5\,\mu\text{m} < d < 5.8\,\mu\text{m}}$$

26 •• Light that has a wavelength equal to 600 nm is used to illuminate two glass plates at normal incidence. The plates are 22 cm in length, touch at one end, and are separated at the other end by a wire that has a radius of 0.025 mm. How many bright fringes appear along the total length of the plates?

Picture the Problem The light reflected from the top surface of the bottom plate (wave 2 in the diagram) is phase shifted relative to the light reflected from the bottom surface of the top plate (wave 1 in the diagram). This phase difference is the sum of a phase shift of π (equivalent to a $\lambda/2$ path difference) resulting from reflection plus a phase shift due to the additional distance traveled.



Relate the extra distance traveled by wave 2 to the distance equivalent to the phase change due to reflection and to the condition for constructive interference:

$$2t + \tfrac{1}{2}\lambda = \lambda, 2\lambda, 3\lambda, \ldots$$

or

$$2t = \tfrac{1}{2}\lambda, \tfrac{3}{2}\lambda, \tfrac{5}{2}\lambda, \ldots$$

and

$$2t = \left(m + \tfrac{1}{2}\right)\lambda \text{ where } m = 0, 1, 2, \ldots,$$

$0 \le t \le 2r$ and λ is the wavelength of light in air.

Solving for m gives:

$$m=\frac{2t}{\lambda}-\frac{1}{2}$$

where m = 0, 1, 2, …and $0\le t\le 2r$

Solve for the highest value of m:

$$m_{\max}=\operatorname{int}\left(\frac{2(2r)}{\lambda}-\frac{1}{2}\right)=\operatorname{int}\left(\frac{4r}{\lambda}-\frac{1}{2}\right)$$

where r is the radius of the wire.

Substitute numerical values and evaluate m:

$$m_{\max}=\operatorname{int}\left(\frac{4(0.025\,\text{mm})}{600\,\text{nm}}-\frac{1}{2}\right)$$
$$=\operatorname{int}(166.2)=166$$

Because we start counting from m = 0, the number of bright fringes is $m_{\max}$ + 1.

$$N=m_{\max}+1=\boxed{167}$$

27 •• A thin film having an index of refraction of 1.50 is surrounded by air. It is illuminated normally by white light. Analysis of the reflected light shows that the wavelengths 360, 450, and 602 nm are the only missing wavelengths in or near the visible portion of the spectrum. That is, for these wavelengths, there is destructive interference. (*a*) What is the thickness of the film? (*b*) What visible wavelengths are brightest in the reflected interference pattern? (*c*) If this film were resting on glass with an index of refraction of 1.60, what wavelengths in the visible spectrum would be missing from the reflected light?

Picture the Problem (*a*) We can use the condition for destructive interference in a thin film to find the thickness of the film. (*b*) and (*c*) Once we've found the thickness of the film, we can use the condition for constructive interference to find the wavelengths in the visible portion of the spectrum that will be brightest in the reflected interference pattern and the condition for destructive interference to find the wavelengths of light missing from the reflected light when the film is placed on glass with an index of refraction greater than that of the film.

(*a*) Express the condition for destructive interference in the thin film:

$$2t + \tfrac{1}{2}\lambda' = \tfrac{1}{2}\lambda', \tfrac{3}{2}\lambda', \tfrac{5}{2}\lambda', ...$$

or

$$2t = \lambda', 2\lambda', 3\lambda', ...$$

or

$$2t = m\lambda' = m\frac{\lambda}{n} \qquad (1)$$

where m = 1, 2, 3, … and λ' is the wavelength of the light in the film.

Solving for λ yields:

$$\lambda = \frac{2nt}{m}$$

Substitute for the missing wavelengths to obtain:

$$450\,\text{nm} = \frac{2nt}{m} \text{ and } 360\,\text{nm} = \frac{2nt}{m+1}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{450\,\text{nm}}{360\,\text{nm}} = \frac{\frac{2nt}{m}}{\frac{2nt}{m+1}} = \frac{m+1}{m}$$

Solving for m gives:

$$m = 4 \text{ for } \lambda = 450\,\text{nm}$$

Solve equation (1) for t to obtain:

$$t = \frac{m\lambda}{2n}$$

Substitute numerical values and evaluate t:

$$t = \frac{4(450\,\text{nm})}{2(1.50)} = \boxed{600\,\text{nm}}$$

(*b*) The condition for constructive interference in the thin film is:

$$2t + \tfrac{1}{2}\lambda' = \lambda', 2\lambda', 3\lambda', ...$$

or

$$2t = \tfrac{1}{2}\lambda', \tfrac{3}{2}\lambda', \tfrac{5}{2}\lambda', ... = \left(m + \tfrac{1}{2}\right)\lambda'$$

where λ' is the wavelength of light in the oil and m = 0, 1, 2, …

Substitute for λ' to obtain:

$$2t = \left(m + \tfrac{1}{2}\right)\frac{\lambda}{n} \Rightarrow \lambda = \frac{2nt}{m + \frac{1}{2}}$$

where n is the index of refraction of the film.

Substitute numerical values and simplify to obtain:

$$\lambda = \frac{2(1.50)(600\,\text{nm})}{m + \frac{1}{2}} = \frac{1800\,\text{nm}}{m + \frac{1}{2}}$$

Substitute numerical values for m and evaluate λ to obtain the following table:

m	0	1	2	3	4	5
λ (nm)	3600	1200	720	514	400	327

From the table, we see that the only wavelengths in the visible spectrum are 720 nm, 514 nm, and 400 nm.

(*c*) Because the index of refraction of the glass is greater than that of the film, the light reflected from the film-glass interface will be shifted by $\frac{1}{2}\lambda$ (as is the wave reflected from the top surface) and the condition for destructive interference becomes:

$$2t = \tfrac{1}{2}\lambda', \tfrac{3}{2}\lambda', \tfrac{5}{2}\lambda', ...$$

or

$$2t = \left(m + \tfrac{1}{2}\right)\frac{\lambda}{n}$$

where n is the index of refraction of the film and m = 0, 1, 2, …

Solving for λ yields:

$$\lambda = \frac{2nt}{m + \frac{1}{2}}$$

Substitute numerical values and simplify to obtain:

$$\lambda = \frac{2(1.5)(600\,\text{nm})}{m + \frac{1}{2}} = \frac{1800\,\text{nm}}{m + \frac{1}{2}}$$

Substitute numerical values for m and evaluate λ to obtain the following table:

m	0	1	2	3	4	5
λ (nm)	3600	1200	720	514	400	327

From the table we see that the missing wavelengths in the visible spectrum are 720 nm, 514 nm, and 400 nm.

28 •• A drop of oil (refractive index of 1.22) floats on water (refractive index of 1.33). When reflected light is observed from above, as shown in Figure 33-41 what is the thickness of the drop at the point where the second red fringe, counting from the edge of the drop, is observed? Assume red light has a wavelength of 650 nm.

Picture the Problem Because there is a $\frac{1}{2}\lambda$ phase change due to reflection at both the air-oil and oil-water interfaces, the condition for constructive interference is that twice the thickness of the oil film equal an integer multiple of the wavelength of light in the film.

The condition for constructive interference is:

$$2t = \lambda', 2\lambda', 3\lambda', ...$$

or

$$2t = m\lambda' \qquad (1)$$

where λ' is the wavelength of light in the oil and m = 1, 2, 3, …

Substitute for λ' to obtain:

$$2t = m\frac{\lambda}{n} \Rightarrow t = \frac{m\lambda}{2n}$$

Substitute numerical values and evaluate t:

$$t = \frac{(2)(650\,\text{nm})}{2(1.22)} = \boxed{533\,\text{nm}}$$

29 •• [SSM] A film of oil that has an index of refraction of 1.45 rests on an optically flat piece of glass with an index of refraction of 1.60. When illuminated by white light at normal incidence, light of wavelengths 690 nm and 460 nm is predominant in the reflected light. Determine the thickness of the oil film.

Picture the Problem Because there is a $\frac{1}{2}\lambda$ phase change due to reflection at both the air-oil and oil-glass interfaces, the condition for constructive interference is that twice the thickness of the oil film equal an integer multiple of the wavelength of light in the film.

Express the condition for constructive interference:

$$2t = \lambda', 2\lambda', 3\lambda', ... = m\lambda' \qquad (1)$$

where λ' is the wavelength of light in the oil and m = 0, 1, 2, …

Substitute for λ' to obtain:

$$2t = m\frac{\lambda}{n} \Rightarrow \lambda = \frac{2nt}{m}$$

where n is the index of refraction of the oil.

Substitute for the predominant wavelengths to obtain:

$$690\,\text{nm} = \frac{2nt}{m} \text{ and } 460\,\text{nm} = \frac{2nt}{m+1}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{690\,\text{nm}}{460\,\text{nm}} = \frac{\frac{2nt}{m}}{\frac{2nt}{m+1}} = \frac{m+1}{m} \Rightarrow m = 2$$

Solve equation (1) for t:

$$t = \frac{m\lambda}{2n}$$

Substitute numerical values and evaluate t:

$$t=\frac{(2)(690\,\text{nm})}{2(1.45)}=\boxed{476\,\text{nm}}$$

30 •• A film of oil that has an index of refraction 1.45 floats on water. When illuminated with white light at normal incidence, light of wavelengths 700 nm and 500 nm is predominant in the reflected light. Determine the thickness of the oil film.

Picture the Problem Because the index of refraction of air is less than that of the oil, there is a phase shift of π rad ($\frac{1}{2}\lambda$) in the light reflected at the air-oil interface. Because the index of refraction of the oil is greater than that of the glass, there is no phase shift in the light reflected from the oil-glass interface. We can use the condition for constructive interference to determine m for λ = 700 nm and then use this value in our equation describing constructive interference to find the thickness t of the oil film.

Express the condition for constructive interference between the waves reflected from the air-oil interface and the oil-glass interface:

$$2t+\tfrac{1}{2}\lambda'=\lambda',2\lambda',3\lambda',...$$

or

$$2t=\tfrac{1}{2}\lambda',\tfrac{3}{2}\lambda',\tfrac{5}{2}\lambda',...=\left(m+\tfrac{1}{2}\right)\lambda' \qquad (1)$$

where λ' is the wavelength of light in the oil and m = 0, 1, 2, …

Substitute for λ' and solve for λ to obtain:

$$\lambda=\frac{2nt}{m+\frac{1}{2}}$$

Substitute the predominant wavelengths to obtain:

$$700\,\text{nm}=\frac{2nt}{m+\frac{1}{2}} \text{ and } 500\,\text{nm}=\frac{2nt}{m+\frac{3}{2}}$$

Divide the first of these equations by the second to obtain:

$$\frac{700\,\text{nm}}{500\,\text{nm}}=\frac{\dfrac{2nt}{m+\frac{1}{2}}}{\dfrac{2nt}{m+\frac{3}{2}}}=\frac{m+\frac{3}{2}}{m+\frac{1}{2}}\Rightarrow m=2$$

Solve equation (1) for t:

$$t=\left(m+\tfrac{1}{2}\right)\frac{\lambda}{2n}$$

Substitute numerical values and evaluate t:

$$t=\left(2+\tfrac{1}{2}\right)\frac{700\,\text{nm}}{2(1.45)}=\boxed{603\,\text{nm}}$$

Newton's Rings

31 •• [SSM] A Newton's ring apparatus consists of a plano-convex glass lens with radius of curvature R that rests on a flat glass plate, as shown in Figure 33-42. The thin film is air of variable thickness. The apparatus is illuminated from above by light from a sodium lamp that has a wavelength of 590 nm. The pattern is viewed by reflected light. (*a*) Show that for a thickness t the condition for a bright (constructive) interference ring is $2t = \left(m + \frac{1}{2}\right)\lambda$ where m = 0, 1, 2, . . .
(*b*) Show that for $t << R$, the radius r of a fringe is related to t by $r = \sqrt{2tR}$.
(*c*) For a radius of curvature of 10.0 m and a lens diameter of 4.00 cm. How many bright fringes would you see in the reflected light? (*d*) What would be the diameter of the sixth bright fringe? (*e*) If the glass used in the apparatus has an index of refraction n = 1.50 and water replaces the air between the two pieces of glass, explain qualitatively the changes that will take place in the bright-fringe pattern.

Picture the Problem This arrangement is essentially identical to a ″thin film″ configuration, except that the ″film″ is air. A phase change of 180° ($\frac{1}{2}\lambda$) occurs at the top of the flat glass plate. We can use the condition for constructive interference to derive the result given in (*a*) and use the geometry of the lens on the plate to obtain the result given in (*b*). We can then use these results in the remaining parts of the problem.

(*a*) The condition for constructive interference is:

$$2t + \tfrac{1}{2}\lambda = \lambda, 2\lambda, 3\lambda, ...$$

or

$$2t = \tfrac{1}{2}\lambda, \tfrac{3}{2}\lambda, \tfrac{5}{2}\lambda, ... = \left(m + \tfrac{1}{2}\right)\lambda$$

where λ is the wavelength of light in air and m = 0, 1, 2, …

Solving for t yields:

$$t = \boxed{\left(m + \tfrac{1}{2}\right)\frac{\lambda}{2}, m = 0, 1, 2, ...} \qquad (1)$$

(*b*) From Figure 33-42 we have:

$$r^2 + (R - t)^2 = R^2$$

or

$$R^2 = r^2 + R^2 - 2Rt + t^2$$

For $t << R$ we can neglect the last term to obtain:

$$R^2 \approx r^2 + R^2 - 2Rt \Rightarrow r = \boxed{\sqrt{2Rt}} \qquad (2)$$

(*c*) Square equation (2) and substitute for t from equation (1) to obtain:

$$r^2 = \left(m + \tfrac{1}{2}\right)R\lambda \Rightarrow m = \frac{r^2}{R\lambda} - \frac{1}{2}$$

Substitute numerical values and evaluate m:

$$m = \frac{(2.00\,\text{cm})^2}{(10.0\,\text{m})(590\,\text{nm})} - \frac{1}{2} = 67$$

and so there will be $\boxed{68}$ bright fringes.

(d) The diameter of the m^{th} fringe is:

$$D = 2r = 2\sqrt{\left(m + \tfrac{1}{2}\right)R\lambda}$$

Noting that m = 5 for the sixth fringe, substitute numerical values and evaluate D:

$$D = 2\sqrt{\left(5 + \tfrac{1}{2}\right)(10.0\,\text{m})(590\,\text{nm})} = \boxed{1.14\,\text{cm}}$$

(e) The wavelength of the light in the film becomes λ_{air}/n = 444 nm. The separation between fringes is reduced (the fringes would become more closely spaced.) and the number of fringes that will be seen is increased by a factor of 1.33.

32 •• A plano-convex glass lens of radius of curvature 2.00 m rests on an optically flat glass plate. The arrangement is illuminated from above with monochromatic light of 520-nm wavelength. The indexes of refraction of the lens and plate are 1.60. Determine the radii of the first and second bright fringe from the center in the reflected light.

Picture the Problem This arrangement is essentially identical to a ″thin film″ configuration, except that the ″film″ is air. A phase change of 180° ($\frac{1}{2}\lambda$) occurs at the top of the flat glass plate. We can use the condition for constructive interference and the results from Problem 31(b) to determine the radii of the first and second bright fringes in the reflected light.

The condition for constructive interference is:

$$2t + \tfrac{1}{2}\lambda = \lambda, 2\lambda, 3\lambda, \ldots$$

or

$$2t = \tfrac{1}{2}\lambda, \tfrac{3}{2}\lambda, \tfrac{5}{2}\lambda, \ldots = \left(m + \tfrac{1}{2}\right)\lambda$$

where λ is the wavelength of light in air and m = 0, 1, 2, …

Solving for t gives:

$$t = \left(m + \tfrac{1}{2}\right)\frac{\lambda}{2},\ m = 0, 1, 2, \ldots$$

In Problem 31(b) it was shown that:

$$r = \sqrt{2tR}$$

Substitute for t to obtain:

$$r = \sqrt{\left(m + \tfrac{1}{2}\right)\lambda R}$$

The first fringe corresponds to $m = 0$:

$$r = \sqrt{\tfrac{1}{2}(520\,\text{nm})(2.00\,\text{m})} = \boxed{0.721\,\text{mm}}$$

The second fringe corresponds to $m = 1$:

$$r = \sqrt{\tfrac{3}{2}(520\,\text{nm})(2.00\,\text{m})} = \boxed{1.25\,\text{mm}}$$

33 ••• Suppose that before the lens of Problem 32 is placed on the plate, a film of oil of refractive index 1.82 is deposited on the plate. What will then be the radii of the first and second bright fringes?

Picture the Problem This arrangement is essentially identical to a ″thin film″ configuration, except that the ″film″ is oil. A phase change of 180° ($\frac{1}{2}\lambda$) occurs at lens-oil interface. We can use the condition for constructive interference and the results from Problem 31(*b*) to determine the radii of the first and second bright fringes in the reflected light.

The condition for constructive interference is:

$$2t + \tfrac{1}{2}\lambda' = \lambda', 2\lambda', 3\lambda', ...$$

or

$$2t = \tfrac{1}{2}\lambda', \tfrac{3}{2}\lambda', \tfrac{5}{2}\lambda', ... = \left(m + \tfrac{1}{2}\right)\lambda'$$

where λ' is the wavelength of light in the oil and $m = 0, 1, 2, \ldots$

Substitute for λ' and solve for t:

$$t = \left(m + \tfrac{1}{2}\right)\frac{\lambda}{2n}, m = 0, 1, 2, ...$$

where λ is the wavelength of light in air.

In Problem 31(*b*) it was shown that:

$$r = \sqrt{2tR}$$

Substitute for t to obtain:

$$r = \sqrt{\left(m + \tfrac{1}{2}\right)\frac{\lambda R}{n}}$$

The first fringe corresponds to $m = 0$:

$$r = \sqrt{\frac{1}{2}\frac{(520\,\text{nm})(2.00\,\text{m})}{1.82}} = \boxed{0.535\,\text{mm}}$$

The second fringe corresponds to $m = 1$:

$$r = \sqrt{\frac{3}{2}\frac{(520\,\text{nm})(2.00\,\text{m})}{1.82}} = \boxed{0.926\,\text{mm}}$$

Two-Slit Interference Patterns

34 • Two narrow slits separated by 1.00 mm are illuminated by light of wavelength 600 nm, and the interference pattern is viewed on a screen 2.00 m

away. Calculate the number of bright fringes per centimeter on the screen in the region near the center fringe.

Picture the Problem The number of bright fringes per unit distance is the reciprocal of the separation of the fringes. We can use the expression for the distance on the screen to the *m*th fringe to find the separation of the fringes.

Express the number N of bright fringes per centimeter in terms of the separation of the fringes:

$$N=\frac{1}{\Delta y} \qquad (1)$$

Express the distance on the screen to the *m*th and (m + 1)st bright fringe:

$$y_m=m\frac{\lambda L}{d} \text{ and } y_{m+1}=(m+1)\frac{\lambda L}{d}$$

Subtract the first of these equations from the second to obtain:

$$\Delta y=\frac{\lambda L}{d}$$

Substitute in equation (1) to obtain:

$$N=\frac{d}{\lambda L}$$

Substitute numerical values and evaluate N:

$$N=\frac{1.00\,\text{mm}}{(600\,\text{nm})(2.00\,\text{m})}=\boxed{8.33\,\text{cm}^{-1}}$$

35 • **[SSM]** Using a conventional two-slit apparatus with light of wavelength 589 nm, 28 bright fringes per centimeter are observed near the center of a screen 3.00 m away. What is the slit separation?

Picture the Problem We can use the expression for the distance on the screen to the *m*th and (m + 1)st bright fringes to obtain an expression for the separation Δy of the fringes as a function of the separation of the slits d. Because the number of bright fringes per unit length N is the reciprocal of Δy, we can find d from N, λ, and L.

Express the distance on the screen to the *m*th and (m + 1)st bright fringe:

$$y_m=m\frac{\lambda L}{d} \text{ and } y_{m+1}=(m+1)\frac{\lambda L}{d}$$

Subtract the first of these equations from the second to obtain:

$$\Delta y=\frac{\lambda L}{d}\Rightarrow d=\frac{\lambda L}{\Delta y}$$

Because the number of fringes per unit length N is the reciprocal of Δy:

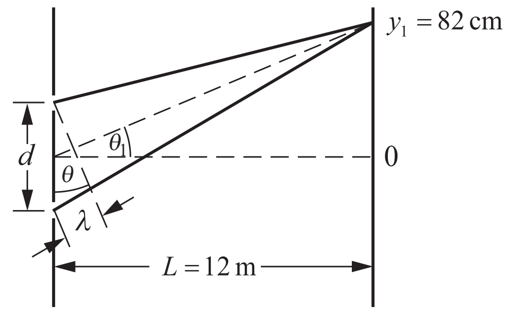
$$d=N\lambda L$$

Substitute numerical values and evaluate d:

$$d = (28\,\text{cm}^{-1})(589\,\text{nm})(3.00\,\text{m}) = \boxed{4.95\,\text{mm}}$$

36 • Light of wavelength 633 nm from a helium–neon laser is shone normally on a plane containing two slits. The first interference maximum is 82 cm from the central maximum on a screen 12 m away. (*a*) Find the separation of the slits. (*b*) How many interference maxima is it, in principle, possible to observe?

Picture the Problem We can use the geometry of the setup, represented to the right, to find the separation of the slits. To find the number of interference maxima that, in principle, can be observed, we can apply the equation describing two-slit interference maxima and require that $\sin\theta \le 1$.



Because $d << L$, we can approximate $\sin\theta_1$ as:

$$\sin\theta_1 \approx \frac{\lambda}{d} \Rightarrow d \approx \frac{\lambda}{\sin\theta_1} \qquad (1)$$

From the right triangle whose sides are L and y_1 we have:

$$\sin\theta_1 = \frac{82\,\text{cm}}{\sqrt{(12\,\text{m})^2 + (82\,\text{cm})^2}} = 0.06817$$

Substitute numerical values in equation (1) and evaluate d:

$$d \approx \frac{633\,\text{nm}}{0.06817} = 9.29\,\mu\text{m} = \boxed{9.3\,\mu\text{m}}$$

(*b*) The equation describing two-slit interference maxima is:

$$d\sin\theta = m\lambda, m = 0, 1, 2, \ldots$$

Because $\sin\theta \le 1$ determines the maximum number of interference fringes that can be seen:

$$d = m_{\text{max}}\lambda \Rightarrow m_{\text{max}} = \frac{d}{\lambda}$$

Substitute numerical values and evaluate m_{max}:

$$m_{\text{max}} = \frac{9.29\,\mu\text{m}}{633\,\text{nm}} = 14$$ because m must be an integer.

Because there are 14 fringes on either side of the central maximum:

$$N = 2m_{\text{max}} + 1 = 2(14) + 1 = \boxed{29}$$

37 •• Two narrow slits are separated by a distance *d*. Their interference pattern is to be observed on a screen a large distance *L* away. (*a*) Calculate the spacing between successive maxima near the center fringe for light of wavelength 500 nm, when *L* is 1.00 m and *d* is 1.00 cm. (*b*) Would you expect to be able to observe the interference of light on the screen for this situation? (*c*) How close together should the slits be placed for the maxima to be separated by 1.00 mm for this wavelength and screen distance?

Picture the Problem We can use the equation for the distance on a screen to the *m*th bright fringe to derive an expression for the spacing of the maxima on the screen. In (c) we can use this same relationship to express the slit separation *d*.

(*a*) Express the distance on the screen to the *m*th and (*m* + 1)st bright fringe:

$$y_m = m\frac{\lambda L}{d} \text{ and } y_{m+1} = (m+1)\frac{\lambda L}{d}$$

Subtract the first of these equations from the second to obtain:

$$\Delta y = \frac{\lambda L}{d} \qquad (1)$$

Substitute numerical values and evaluate Δy:

$$\Delta y = \frac{(500\,\text{nm})(1.00\,\text{m})}{1.00\,\text{cm}} = \boxed{50.0\,\mu\text{m}}$$

(*b*) According to the Raleigh criterion you could resolve them, but not by much.

(*c*) Solve equation (1) for *d* to obtain:

$$d = \frac{\lambda L}{\Delta y}$$

Substitute numerical values and evaluate *d*:

$$d = \frac{(500\,\text{nm})(1.00\,\text{m})}{1.00\,\text{mm}} = \boxed{0.500\,\text{mm}}$$

38 •• Light is incident at an angle ϕ with the normal to a vertical plane containing two slits of separation *d* (Figure 33-43). Show that the interference maxima are located at angles θ_m given by $\sin\theta_m + \sin\phi = m\lambda/d$.

Picture the Problem Let the separation of the slits be *d*. We can find the total path difference when the light is incident at an angle ϕ and set this result equal to an integer multiple of the wavelength of the light to obtain the given equation.

Express the total path difference:

$$\Delta\ell = d\sin\phi + d\sin\theta_m$$

The condition for constructive interference is:

$$\Delta\ell = m\lambda$$

where *m* is an integer.

Substitute to obtain: $d\sin\phi + d\sin\theta_{\mathrm{m}} = m\lambda$

Divide both sides of the equation by d to obtain:

$$\boxed{\sin\phi + \sin\theta_{\mathrm{m}} = \frac{m\lambda}{d}}$$

39 •• [SSM] White light falls at an angle of 30º to the normal of a plane containing a pair of slits separated by 2.50 μm. What visible wavelengths give a bright interference maximum in the transmitted light in the direction normal to the plane? (See Problem 38.)

Picture the Problem Let the separation of the slits be d. We can find the total path difference when the light is incident at an angle ϕ and set this result equal to an integer multiple of the wavelength of the light to relate the angle of incidence on the slits to the direction of the transmitted light and its wavelength.

Express the total path difference: $\Delta\ell = d\sin\phi + d\sin\theta$

The condition for constructive interference is: $\Delta\ell = m\lambda$ where m is an integer.

Substitute to obtain: $d\sin\phi + d\sin\theta = m\lambda$

Divide both sides of the equation by d to obtain:

$$\sin\phi + \sin\theta = \frac{m\lambda}{d}$$

Set $\theta = 0$ and solve for λ:

$$\lambda = \frac{d\sin\phi}{m}$$

Substitute numerical values and simplify to obtain:

$$\lambda = \frac{(2.50\,\mu\text{m})\sin 30^\circ}{m} = \frac{1.25\,\mu\text{m}}{m}$$

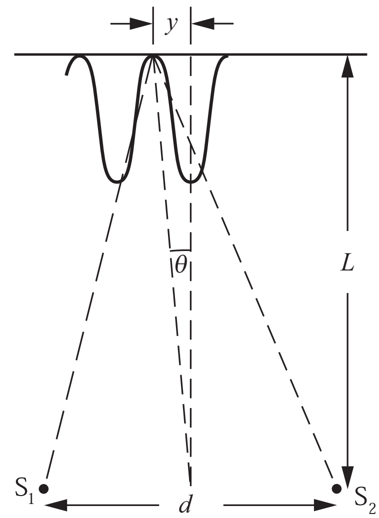
Evaluate λ for positive integral values of m:

m	λ (nm)
1	1250
2	625
3	417
4	313

From the table we can see that 625 nm and 417 nm are in the visible portion of the electromagnetic spectrum.

40 •• Two small loudspeakers are separated by 5.0 cm, as shown in Figure 33-44. The speakers are driven in phase with a sine wave signal of frequency 10 kHz. A small microphone is placed a distance 1.00 m away from the speakers on the axis running through the middle of the two speakers, and the microphone is then moved perpendicular to the axis. Where does the microphone record the first minimum and the first maximum of the interference pattern from the speakers? The speed of sound in air is 343 m/s.

Picture the Problem The diagram shows the two speakers, S_1 and S_2, the central-bright image and the first-order image to the left of the central-bright image. The distance *y* is measured from the center of the central-bright image. We can apply the conditions for constructive and destructive interference from two sources and use the geometry of the speakers and microphone to find the distance to the first interference minimum and the distance to the first interference maximum.



Relate the distance Δy to the first minimum from the center of the central maximum to θ and the distance L from the speakers to the plane of the microphone:

$$\tan\theta = \frac{y}{L} \Rightarrow y = L\tan\theta \qquad (1)$$

Interference minima occur where:

$$d\sin\theta = \left(m + \tfrac{1}{2}\right)\lambda$$
where m = 0, 1, 2, 3, …

Solve for θ to obtain:

$$\theta = \sin^{-1}\left[\frac{\left(m+\frac{1}{2}\right)\lambda}{d}\right]$$

Relate the wavelength λ of the sound waves to the speed of sound v and the frequency f of the sound:

$$\lambda = \frac{v}{f}$$

Substitute for λ in the expression for θ to obtain:

$$\theta = \sin^{-1}\left[\frac{\left(m+\frac{1}{2}\right)v}{df}\right]$$

Substituting for θ in equation (1) yields:

$$y = L\tan\left\{\sin^{-1}\left[\frac{\left(m+\frac{1}{2}\right)v}{df}\right]\right\} \qquad (2)$$

Noting that the first minimum corresponds to $m = 0$, substitute numerical values and evaluate Δy:

$$y_{\text{1st min}} = (1.00\,\text{m})\tan\left\{\sin^{-1}\left[\frac{\left(\frac{1}{2}\right)(343\,\text{m/s})}{(5.0\,\text{cm})(10\,\text{kHz})}\right]\right\} = \boxed{37\,\text{cm}}$$

The maxima occur where:

$$d\sin\theta = m\lambda$$
where $m = 1, 2, 3, \ldots$

For diffraction maxima, equation (2) becomes:

$$y = L\tan\left\{\sin^{-1}\left[\frac{mv}{af}\right]\right\}$$

Noting that the first maximum corresponds to $m = 1$, substitute numerical values and evaluate y:

$$y_{\text{1st max}} = (1.00\,\text{m})\tan\left\{\sin^{-1}\left[\frac{(1)(343\,\text{m/s})}{(5.0\,\text{cm})(10\,\text{kHz})}\right]\right\} = \boxed{94\,\text{cm}}$$

Diffraction Pattern of a Single Slit

41 • Light that has a 600-nm wavelength is incident on a long narrow slit. Find the angle of the first diffraction minimum if the width of the slit is (*a*) 1.0 mm, (*b*) 0.10 mm, and (*c*) 0.010 mm.

Picture the Problem We can use the expression locating the first zeroes in the intensity to find the angles at which these zeroes occur as a function of the slit width *a*.

The first zeroes in the intensity occur at angles given by:

$$\sin\theta = \frac{\lambda}{a} \Rightarrow \theta = \sin^{-1}\left(\frac{\lambda}{a}\right)$$

(*a*) For $a = 1.0$ mm:

$$\theta = \sin^{-1}\left(\frac{600\,\text{nm}}{1.0\,\text{mm}}\right) = \boxed{0.60\,\text{mrad}}$$

(*b*) For $a = 0.10$ mm:

$$\theta = \sin^{-1}\left(\frac{600\,\text{nm}}{0.10\,\text{mm}}\right) = \boxed{6.0\,\text{mrad}}$$

(*c*) For $a = 0.010$ mm:

$$\theta = \sin^{-1}\left(\frac{600\,\text{nm}}{0.010\,\text{mm}}\right) = \boxed{60\,\text{mrad}}$$

42 • Plane microwaves are incident on the thin metal sheet that has a long, narrow slit of width 5.0 cm in it. The microwave radiation strikes the sheet at normal incidence. The first diffraction minimum is observed at $\theta = 37°$. What is the wavelength of the microwaves?

Picture the Problem We can use the expression locating the first zeroes in the intensity to find the wavelength of the radiation as a function of the angle at which the first diffraction minimum is observed and the width of the plate.

The first zeroes in the intensity occur at angles given by:

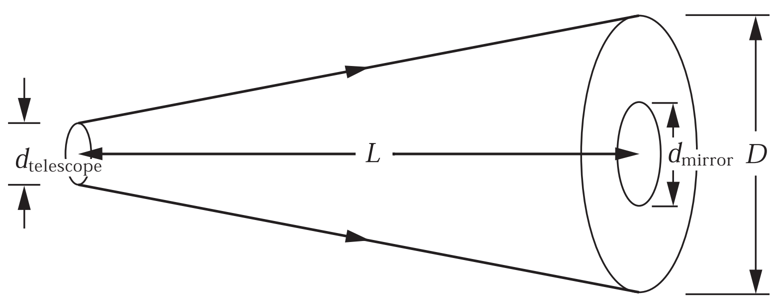
$$\sin\theta = \frac{\lambda}{a} \Rightarrow \lambda = a\sin\theta$$

Substitute numerical values and evaluate λ:

$$\lambda = (5.0\,\text{cm})\sin 37° = \boxed{3.0\,\text{cm}}$$

43 ••• **[SSM]** Measuring the distance to the moon (lunar ranging) is routinely done by firing short-pulse lasers and measuring the time it takes for the pulses to reflect back from the moon. A pulse is fired from Earth. To send the pulse out, the pulse is expanded so that it fills the aperture of a 6.00-in-diameter telescope. Assuming the only thing spreading the beam out is diffraction and that the light wavelength is 500 nm, how large will the beam be when it reaches the Moon, 3.82×10^5 km away?

Picture the Problem The diagram shows the beam expanding as it travels to the moon and that portion of it that is reflected from the mirror on the moon expanding as it returns to Earth. We can express the diameter of the beam at the moon as the product of the beam divergence angle and the distance to the moon and use the equation describing diffraction at a circular aperture to find the beam divergence angle.



Relate the diameter D of the beam when it reaches the moon to the distance to the moon L and the beam divergence angle θ:

$$D \approx \theta L \qquad (1)$$

The angle θ subtended by the first diffraction minimum is related to the wavelength λ of the light and the diameter of the telescope opening $d_{\text{telescope}}$ by:

$$\sin\theta = 1.22\frac{\lambda}{d_{\text{telescope}}}$$

Because $\theta << 1$, $\sin\theta \approx \theta$ and:

$$\theta \approx 1.22\frac{\lambda}{d_{\text{telescope}}}$$

Substitute for θ in equation (1) to obtain:

$$D = \frac{1.22L\lambda}{d_{\text{telescope}}}$$

Substitute numerical values and evaluate D:

$$D = \left(3.82\times10^{8}\text{ m}\right)\left[\frac{1.22(500\text{ nm})}{6.00\text{ in}\times\frac{2.54\text{ cm}}{\text{in}}\times\frac{1\text{ m}}{10^{2}\text{ cm}}}\right] = \boxed{1.53\text{ km}}$$

Interference-Diffraction Pattern of Two Slits

44 • How many interference maxima will be contained in the central diffraction maximum in the interference–diffraction pattern of two slits if the separation of the slits is exactly 5 times their width? How many will there be if the slit separation is an integral multiple of the slit width (that is $d = na$) for any value of n?

Picture the Problem We need to find the value of m for which the mth interference maximum coincides with the first diffraction minimum. Then there will be $N = 2m - 1$ fringes in the central maximum.

The number of fringes N in the central maximum is:

$$N = 2m - 1 \qquad (1)$$

Relate the angle θ_1 of the first diffraction minimum to the width a of the slits of the diffraction grating:

$$\sin\theta_1 = \frac{\lambda}{a}$$

Express the angle θ_m corresponding to the mth interference maxima in terms of the separation d of the slits:

$$\sin\theta_m = \frac{m\lambda}{d}$$

Because we require that $\theta_1 = \theta_m$, we can equate these expressions to obtain:

$$\frac{m\lambda}{d} = \frac{\lambda}{a} \Rightarrow m = \frac{d}{a}$$

Substituting for d and simplifying yields:

$$m = \frac{5a}{a} = 5$$

Substitute for m in equation (1) to obtain:

$$N = 2(5) - 1 = \boxed{9}$$

If $d = na$:

$$m = \frac{d}{a} = \frac{na}{a} = n \text{ and } N = \boxed{2n - 1}$$

45 •• [SSM] A two-slit Fraunhofer interference–diffraction pattern is observed using light that has a wavelength equal to 500 nm. The slits have a separation of 0.100 mm and an unknown width. (*a*) Find the width if the fifth interference maximum is at the same angle as the first diffraction minimum. (*b*) For that case, how many bright interference fringes will be seen in the central diffraction maximum?

Picture the Problem We can equate the sine of the angle at which the first diffraction minimum occurs to the sine of the angle at which the fifth interference maximum occurs to find a. We can then find the number of bright interference fringes seen in the central diffraction maximum using $N = 2m - 1$.

(*a*) Relate the angle θ_1 of the first diffraction minimum to the width a of the slits of the diffraction grating:

$$\sin\theta_1 = \frac{\lambda}{a}$$

Express the angle θ_5 corresponding to the m^{th} fifth interference maxima maximum in terms of the separation d of the slits:

$$\sin\theta_5 = \frac{5\lambda}{d}$$

Because we require that $\theta_1 = \theta_{m5}$, we can equate these expressions to obtain:

$$\frac{5\lambda}{d} = \frac{\lambda}{a} \Rightarrow a = \frac{d}{5}$$

Substituting the numerical value of d yields:

$$a = \frac{0.100\,\text{mm}}{5} = \boxed{20.0\,\mu\text{m}}$$

(*b*) Because $m = 5$:

$$N = 2m - 1 = 2(5) - 1 = \boxed{9}$$

46 •• A two-slit Fraunhofer interference–diffraction pattern is observed using light that has a wavelength equal to 700 nm. The slits have widths of 0.010 mm and are separated by 0.20 mm. How many bright fringes will be seen in the central diffraction maximum?

Picture the Problem We can equate the sine of the angle at which the first diffraction minimum occurs to the sine of the angle at which the *m*th interference maximum occurs to find *m*. We can then find the number of bright interference fringes seen in the central diffraction maximum using $N = 2m - 1$.

The number of fringes *N* in the central maximum is:

$$N = 2m - 1 \quad (1)$$

Relate the angle θ_1 of the first diffraction minimum to the width *a* of the slits of the diffraction grating:

$$\sin\theta_1 = \frac{\lambda}{a}$$

Express the angle θ_m corresponding to the *m*th interference maxima in terms of the separation *d* of the slits:

$$\sin\theta_m = \frac{m\lambda}{d}$$

Because we require that $\theta_1 = \theta_m$, we can equate these expressions to obtain:

$$\frac{m\lambda}{d} = \frac{\lambda}{a} \Rightarrow m = \frac{d}{a}$$

Substitute for *m* in equation (1) to obtain:

$$N = \frac{2d}{a} - 1$$

Substitute numerical values and evaluate *N*:

$$N = \frac{2(0.20\,\text{mm})}{0.010\,\text{mm}} - 1 = \boxed{39}$$

47 •• Suppose that the *central* diffraction maximum for two slits has 17 interference fringes for some wavelength of light. How many interference fringes would you expect in the diffraction maximum adjacent to one side of the central diffraction maximum?

Picture the Problem There are 8 interference fringes on each side of the central maximum. The secondary diffraction maximum is half as wide as the central one. It follows that it will contain 8 interference maxima.

48 •• Light that has a wavelength equal to 550 nm illuminates two slits that both have widths equal to 0.030 mm and separations equal to 0.15 mm. (*a*) How many interference maxima fall within the full width of the central diffraction maximum? (*b*) What is the ratio of the intensity of the third interference maximum to one side of the center interference maximum to the intensity of the center interference maximum?

Picture the Problem We can equate the sine of the angle at which the first diffraction minimum occurs to the sine of the angle at which the *m*th interference maximum occurs to find *m*. We can then find the number of bright interference fringes seen in the central diffraction maximum using $N = 2m - 1$. In (*b*) we can use the expression relating the intensity in a single-slit diffraction pattern to phase constant $\phi = \frac{2\pi}{\lambda} a \sin\theta$ to find the ratio of the intensity of the third interference maximum to one side of the center interference maximum.

(*a*) The number of fringes *N* in the central maximum is:

$$N = 2m - 1 \qquad (1)$$

Relate the angle θ_1 of the first diffraction minimum to the width *a* of the slits of the diffraction grating:

$$\sin\theta_1 = \frac{\lambda}{a}$$

Express the angle θ_m corresponding to the *m*th interference maxima in terms of the separation *d* of the slits:

$$\sin\theta_m = \frac{m\lambda}{d}$$

Because we require that $\theta_1 = \theta_m$, we can equate these expressions to obtain:

$$\frac{m\lambda}{d} = \frac{\lambda}{a} \Rightarrow m = \frac{d}{a}$$

Substitute in equation (1) to obtain:

$$N = \frac{2d}{a} - 1$$

Substitute numerical values and evaluate *N*:

$$N = \frac{2(0.15\,\text{mm})}{0.030\,\text{mm}} - 1 = \boxed{9}$$

(*b*) Express the intensity for a single-slit diffraction pattern as a function of the phase difference ϕ:

$$I = I_0\left(\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right)^2 \qquad (2)$$

where $\phi = \frac{2\pi}{\lambda} a \sin\theta$

For $m = 3$:

$$\sin\theta_3 = \frac{3\lambda}{d}$$

and

$$\phi = \frac{2\pi}{\lambda}a\sin\theta_3 = \frac{2\pi}{\lambda}a\left(\frac{3\lambda}{d}\right) = 6\pi\left(\frac{a}{d}\right)$$

Substitute numerical values and evaluate ϕ:

$$\phi = 6\pi\left(\frac{0.030\,\text{mm}}{0.15\,\text{mm}}\right) = \frac{6\pi}{5}$$

Solve equation (2) for the ratio of I_3 to I_0:

$$\frac{I_3}{I_0} = \left(\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right)^2$$

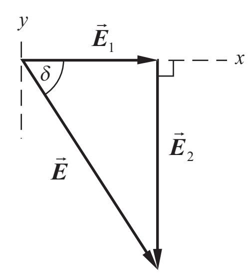
Substitute numerical values and evaluate I_3/I_0:

$$\frac{I_3}{I_0} = \left[\frac{\sin\frac{1}{2}\left(\frac{6\pi}{5}\right)}{\frac{1}{2}\left(\frac{6\pi}{5}\right)}\right]^2 = \boxed{0.25}$$

Using Phasors to Add Harmonic Waves

49 • [SSM] Find the resultant of the two waves whose electric fields at a given location vary with time as follows: $\vec{E}_1 = 2A_0\sin\omega t\,\hat{i}$ and $\vec{E}_2 = 3A_0\sin\left(\omega t + \frac{3}{2}\pi\right)\hat{i}$.

Picture the Problem Chose the coordinate system shown in the phasor diagram. We can use the standard methods of vector addition to find the resultant of the two waves.



The resultant of the two waves is of the form:

$$\vec{E} = \left|\vec{E}\right|\sin(\omega t + \delta)\boldsymbol{i} \qquad (1)$$

The magnitude of $\left|\vec{E}\right|$ is:

$$\left|\vec{E}\right| = \sqrt{(2A_0)^2 + (3A_0)^2} = 3.6A_0$$

The phase angle δ is:

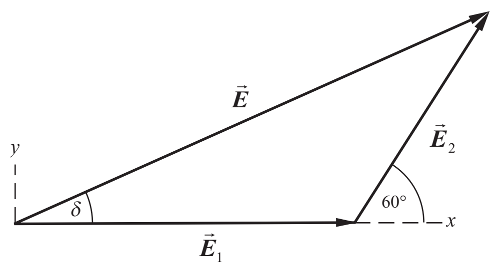
$$\delta = \tan^{-1}\left(\frac{-3A_0}{2A_0}\right) = -0.98\,\text{rad}$$

Substitute for $\left|\vec{E}\right|$ and δ in equation (1) to obtain:

$$\vec{E} = \boxed{3.6A_0 \sin(\omega t - 0.98\,\text{rad})\boldsymbol{i}}$$

50 • Find the resultant of the two waves whose electric fields at a given location vary with time as follows: $\vec{E}_1 = 4A_0 \sin \omega t\,\hat{\boldsymbol{i}}$ and $\vec{E}_2 = 3A_0 \sin\left(\omega t + \frac{1}{6}\pi\right)\hat{\boldsymbol{i}}$.

Picture the Problem Chose the coordinate system shown in the phasor diagram. We can use the standard methods of vector addition to find the resultant of the two waves.



The resultant of the two waves is of the form:

$$\vec{E} = \left|\vec{E}\right| \sin(\omega t + \delta)\boldsymbol{i} \qquad (1)$$

Apply the law of cosines to the magnitudes of the scalars to obtain:

$$\left|\vec{E}\right|^2 = \left|\vec{E}_1\right|^2 + \left|\vec{E}_2\right|^2 - 2\left|\vec{E}_1\right|\left|\vec{E}_2\right|\cos 120°$$

or

$$\left|\vec{E}\right| = \sqrt{\left|\vec{E}_1\right|^2 + \left|\vec{E}_2\right|^2 - 2\left|\vec{E}_1\right|\left|\vec{E}_2\right|\cos 120°}$$

Substitute for $\left|\vec{E}_1\right|$ and $\left|\vec{E}_2\right|$ and evaluate $\left|\vec{E}\right|$ to obtain:

$$\left|\vec{E}\right| = \sqrt{(4A_0)^2 + (3A_0)^2 - 2(4A_0)(3A_0)\cos 120°} = 6.08A_0$$

Applying the law of sines yields:

$$\frac{\sin\delta}{\left|\vec{E}_2\right|} = \frac{\sin 120°}{\left|\vec{E}\right|}$$

Solve for δ to obtain:

$$\delta = \sin^{-1}\left[\frac{\left|\vec{E}_2\right|\sin 120°}{\left|\vec{E}\right|}\right]$$

Substitute numerical values and evaluate δ:

$$\delta = \sin^{-1}\left[\frac{3A_0 \sin 120°}{6.08A_0}\right] = 0.43\,\text{rad}$$

Substitute for $|\vec{E}|$ and δ in equation (1) to obtain:

$$\vec{E} = \boxed{6.1A_0\sin(\omega t + 0.43\,\text{rad})\boldsymbol{i}}$$

Remarks: We could have used the law of cosines to find R and the law of sines to find δ.

51 •• Monochromatic light is incident on a sheet with a long narrow slit (Figure 33-45). Let I_0 be the intensity at the central maximum of the diffraction pattern on a distant screen, and let I be the intensity at the second intensity maximum from the central intensity maximum. The distance from this second intensity maximum to the far edge of the slit is longer than the distance from the second intensity maximum to the near edge of the slit by approximately 2.5 wavelengths. What is the ratio if I to I_0?

Picture the Problem We can evaluate the expression for the intensity for a single-slit diffraction pattern at the second secondary maximum to express I_2 in terms of I_0.

The intensity at the second secondary maximum is given by:

$$I = I_0\left[\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right]^2 \Rightarrow \frac{I}{I_0} = \left[\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right]^2$$

where

$$\phi = \frac{2\pi}{\lambda}a\sin\theta$$

At this second secondary maximum:

$$a\sin\theta = \frac{5}{2}\lambda \text{ and } \phi = \frac{2\pi}{\lambda}\left(\frac{5\lambda}{2}\right) = 5\pi$$

Substitute for ϕ and evaluate $\frac{I}{I_0}$:

$$\frac{I}{I_0} = \left[\frac{\sin\left(\frac{5\pi}{2}\right)}{\frac{5\pi}{2}}\right]^2 = \boxed{0.0162}$$

52 •• Monochromatic light is incident on a sheet that has three long narrow parallel equally spaced slits a distance d apart. (*a*) Show that the positions of the interference minima on a screen a large distance L away from the sheet that has the three equally spaced slits (spacing d, with $d >> \lambda$) are given approximately by $y_m = m\lambda L/3d$ where m = 1, 2, 4, 5, 7, 8, 10, . . . that is, m is *not* a multiple of 3. (*b*) For a screen distance of 1.00 m, a light wavelength of 500 nm, and a source spacing of 0.100 mm, calculate the width of the principal interference maxima (the distance between successive minima) for three sources.

Picture the Problem We can use phasor concepts to find the phase angle δ in terms of the number of phasors N (three in this problem) forming a closed polygon of N sides at the minima and then use this information to express the path difference Δr for each of these locations. Applying a small angle approximation, we can obtain an expression for y that we can evaluate for enough of the path differences to establish the pattern given in the problem statement.

(*a*) Express the phase angle δ in terms of the number of phasors N forming a closed polygon of N sides:

$$\delta = m\left(\frac{2\pi}{N}\right)$$

where m = 1, 2, 3, 4, 5, 6, ,7, …

For three equally spaced sources, the phase angle is:

$$\delta = m\left(\frac{2\pi}{3}\right)$$

Express the path difference corresponding to this phase angle to obtain:

$$\Delta r = \left(\frac{\lambda}{2\pi}\right)\delta = m\frac{\lambda}{3} \qquad (1)$$

Interference maxima occur for: m = 3, 6, 9, 12, …

Interference minima occur for: m = 1, 2, 4, 5, 7, 8, …
(Note that m is not a multiple of 3.)

Express the path difference Δr in terms of $\sin\theta$ and the separation d of the slits:

$$\Delta r = d\sin\theta$$

or, provided the small angle approximation is valid,

$$\Delta r = \frac{yd}{L} \Rightarrow y = \frac{L}{d}\Delta r$$

Substituting for Δr from equation (1) yields:

$$\boxed{y_{\text{min}} = \frac{m\lambda L}{3d},\ m = 1,2,4,5,7,8,...}$$

(*b*) For L = 1.00 m, λ = 500 nm, and d = 0.100 mm:

$$2y_{\text{min}} = \frac{2(500\,\text{nm})(1.00\,\text{m})}{3(0.100\,\text{mm})} = \boxed{3.33\,\text{mm}}$$

53 •• [SSM] Monochromatic light is incident on a sheet that has four long narrow parallel equally spaced slits a distance d apart. (*a*) Show that the positions of the interference minima on a screen a large distance L away from four equally spaced sources (spacing d, with $d >> \lambda$) are given by $y_m = m\lambda L/4d$ where m = 1, 2, 3, 5, 6, 7, 9, 10, . . . that is, m is *not* a multiple of 4. (*b*) For a screen distance of 2.00 m, light wavelength of 600 nm, and a source

spacing of 0.100 mm, calculate the width of the principal interference maxima (the distance between successive minima) for four sources. Compare this width with that for two sources with the same spacing.

Picture the Problem We can use phasor concepts to find the phase angle δ in terms of the number of phasors N (four in this problem) forming a closed polygon of N sides at the minima and then use this information to express the path difference Δr for each of these locations. Applying a small angle approximation, we can obtain an expression for y that we can evaluate for enough of the path differences to establish the pattern given in the problem statement.

(*a*) Express the phase angle δ in terms of the number of phasors N forming a closed polygon of N sides:

$$\delta = m\left(\frac{2\pi}{N}\right)$$

where m = 1, 2, 3, 4, 5, 6, ,7, …

For four equally spaced sources, the phase angle is:

$$\delta = m\left(\frac{\pi}{2}\right)$$

Express the path difference corresponding to this phase angle to obtain:

$$\Delta r = \left(\frac{\lambda}{2\pi}\right)\delta = m\frac{\lambda}{4} \qquad (1)$$

Interference maximum occur for: m = 3, 6, 9, 12, …

Interference minima occur for: m = 1, 2, 4, 5, 7, 8, …
(Note that m is not a multiple of 3.)

Express the path difference Δr in terms of $\sin\theta$ and the separation d of the slits:

$$\Delta r = d\sin\theta$$

or, provided the small angle approximation is valid,

$$\Delta r = \frac{yd}{L} \Rightarrow y = \frac{L}{d}\Delta r$$

Substituting for Δr from equation (1) yields:

$$\boxed{y_{\min} = \frac{m\lambda L}{4d},\ m = 1,2,3,5,6,7,9,...}$$

(*b*) For L = 2.00 m, λ = 600 nm, d = 0.100 mm, and n = 1:

$$2y_{\min} = \frac{2(600\,\text{nm})(2.00\,\text{m})}{4(0.100\,\text{mm})} = \boxed{6.00\,\text{mm}}$$

For two slits:

$$2y_{\min} = \frac{2\left(m+\frac{1}{2}\right)\lambda L}{d}$$

For L = 2.00 m, λ = 600 nm, d = 0.100 mm, and m = 0:

$$2y_{\text{min}} = \frac{(600\,\text{nm})(2.00\,\text{m})}{0.100\,\text{mm}} = 12.0\,\text{mm}$$

The width for four sources is half the width for two sources.

54 •• Light of wavelength 480 nm falls normally on four slits. Each slit is 2.00 μm wide and the center-to-center separation between it and the next slit is 6.00 μm. (*a*) Find the angular width of the of the central intensity maximum of the single-slit diffraction pattern on a distant screen. (*b*) Find the angular position of all interference intensity maxima that lie inside the central diffraction maximum. (*c*) Find the angular width of the central interference. That is, find the angle between the first intensity minima on either side of the central intensity maximum. (*d*) Sketch the relative intensity as a function of the sine of the angle.

Picture the Problem We can use $\sin\theta = \lambda/a$ to find the first zeros in the intensity pattern. The four-slit interference maxima occur at angles given by $d\sin\theta = m\lambda$, where m = 0,1,2, … . In (*c*) we can use the result of Problem 53 to find the angular spread between the central interference maximum and the first interference minimum on either side of it. In (*d*) we'll use a phasor diagram for a four-slit grating to find the resultant amplitude at a given point in the intensity pattern as a function of the phase constant δ, that, in turn, is a function of the angle θ that determines the location of a point in the interference pattern.

(*a*) The first zeros in the intensity occur at angles given by:

$$\sin\theta = \frac{\lambda}{a} \Rightarrow \theta = \sin^{-1}\left(\frac{\lambda}{a}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left(\frac{480\,\text{nm}}{2.00\,\mu\text{m}}\right) = \boxed{242\,\text{mrad}}$$

(*b*) The four-slit interference maxima occur at angles given by:

$$d\sin\theta = m\lambda \Rightarrow \theta_m = \sin^{-1}\left[\frac{m\lambda}{d}\right]$$

where m = 0, 1, 2, 3, …

Substitute numerical values to obtain:

$$\theta_m = \sin^{-1}\left[\frac{m(480\,\text{nm})}{6.00\,\mu\text{m}}\right] = \sin^{-1}(0.0800m)$$

Evaluate θ_m for m = 0, 1, 2, and 3:

$$\theta_0 = \sin^{-1}[0(0.0800)] = \boxed{0}$$
$$\theta_1 = \sin^{-1}[1(0.0800)] = \boxed{\pm 80.1\,\text{mrad}}$$
$$\theta_2 = \sin^{-1}[2(0.0800)] = \boxed{\pm 161\,\text{mrad}}$$
$$\theta_3 = \sin^{-1}[3(0.0800)] = \pm 0.242\,\text{rad}$$

where θ_3 will not be seen as it coincides with the first minimum in the diffraction pattern.

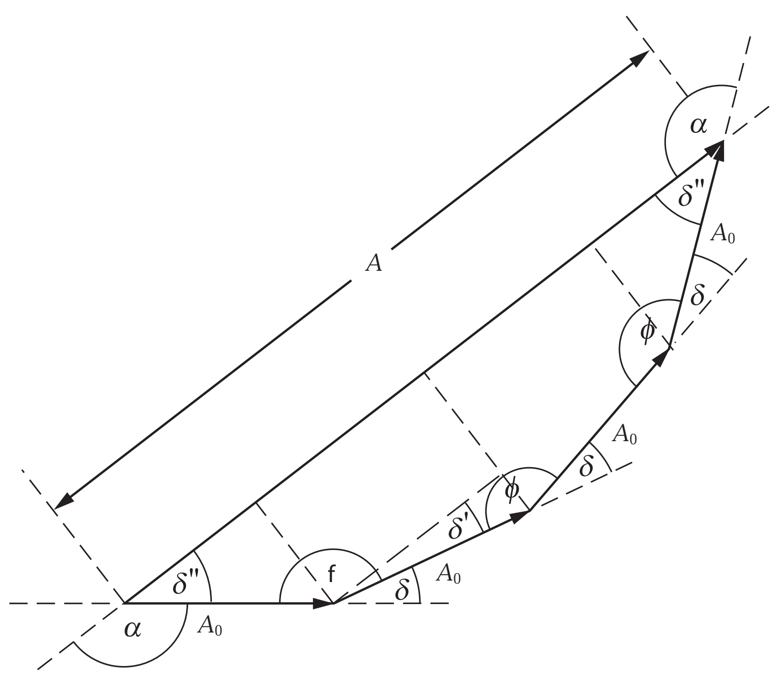
(c) From Problem 53:

$$\theta_{\text{min}} = \frac{n\lambda}{4d}$$

For n = 1:

$$\theta_{\text{min}} = \frac{480\,\text{nm}}{4(6.00\,\mu\text{m})} = \boxed{20\,\text{mrad}}$$

(d) Use the phasor method to show the superposition of four waves of the same amplitude A_0 and constant phase difference $\delta = \dfrac{2\pi}{\lambda} d \sin\theta$.



Express A in terms of δ' and δ'':

$$A = 2(A_0 \cos\delta'' + A_0 \cos\delta') \qquad (1)$$

Because the sum of the external angles of a polygon equals 2π:

$$2\alpha + 3\delta = 2\pi$$

Examining the phasor diagram we see that: $\alpha + \delta'' = \pi$

Eliminate α and solve for δ'' to obtain: $\delta'' = \frac{3}{2}\delta$

Because the sum of the internal angles of a polygon of *n* sides is $(n-2)\pi$: $3\phi + 2\delta'' = 3\pi$

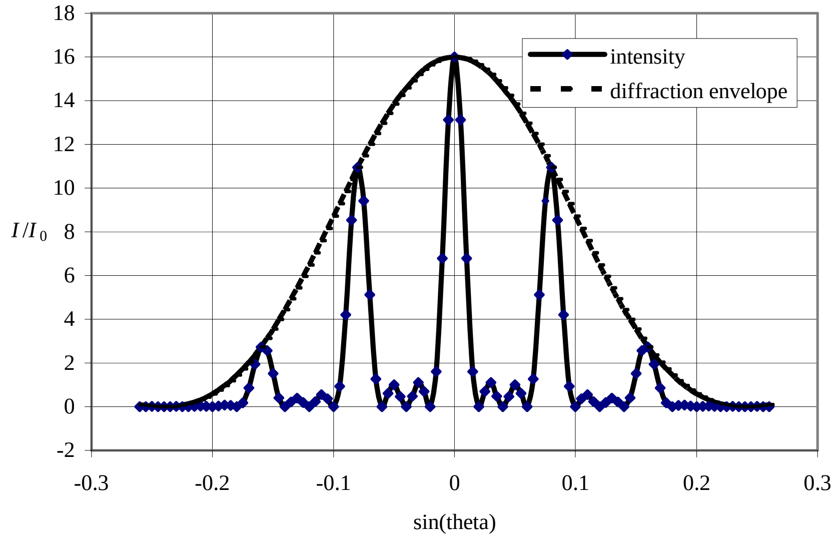
From the definition of a straight angle we have: $\phi - \delta' + \delta = \pi$

Eliminate ϕ between these equations to obtain: $\delta' = \frac{1}{2}\delta$

Substitute for δ'' and δ' in equation (1) to obtain: $A = 2A_0\left(\cos\frac{3}{2}\delta + \cos\frac{1}{2}\delta\right)$

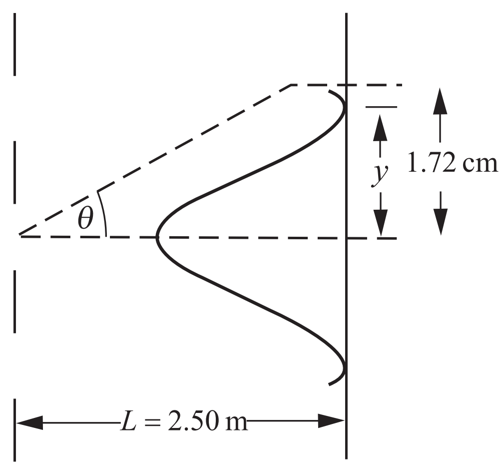
Because the intensity is proportional to the square of the amplitude of the resultant wave: $I = 4I_0\left(\cos\frac{3}{2}\delta + \cos\frac{1}{2}\delta\right)^2$

The following graph of I/I_0 as a function of $\sin\theta$ was plotted using a spreadsheet program. The diffraction envelope was plotted using $\frac{I}{I_0} = 4^2\left(\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right)^2$, where $\phi = \frac{2\pi}{\lambda}a\sin\theta$. Note the excellent agreement with the results calculated in (*a*), (*b*) and (*c*).



55 ••• [SSM] Three slits, each separated from its neighbor by 60.0 μm, are illuminated at the central intensity maximum by a coherent light source of wavelength 550 nm. The slits are extremely narrow. A screen is located 2.50 m from the slits. The intensity is 50.0 mW/m^2. Consider a location 1.72 cm from the central maximum. (*a*) Draw a phasor diagram suitable for the addition of the three harmonic waves at that location. (*b*) From the phasor diagram, calculate the intensity of light at that location.

Picture the Problem We can find the phase constant δ from the geometry of the diagram to the right. Using the value of δ found in this fashion we can express the intensity at the point 1.72 cm from the centerline in terms of the intensity on the centerline. On the centerline, the amplitude of the resultant wave is 3 times that of each individual wave and the intensity is 9 times that of each source acting separately.



(*a*) Express δ for the adjacent slits:

$$\delta = \frac{2\pi}{\lambda} d \sin\theta$$

For $\theta << 1$, $\sin\theta \approx \tan\theta \approx \theta$:

$$\sin\theta \approx \tan\theta = \frac{y}{L}$$

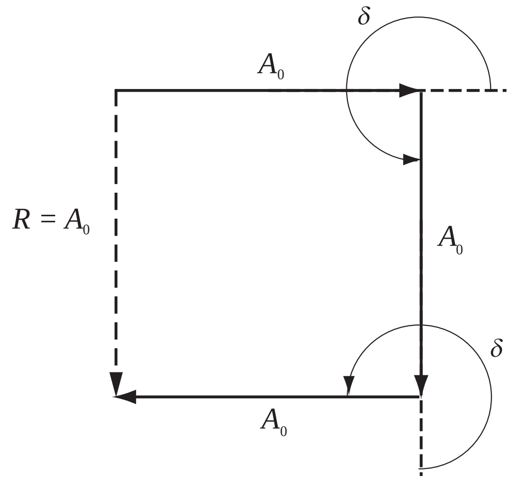
Substitute to obtain:

$$\delta = \frac{2\pi dy}{\lambda L}$$

Substitute numerical values and evaluate δ:

$$\delta = \frac{2\pi(60.0\,\mu\text{m})(1.72\,\text{cm})}{(550\,\text{nm})(2.50\,\text{m})} = \frac{3\pi}{2}\,\text{rad} = 270°$$

The three phasors, 270° apart, are shown in the diagram to the right. Note that they form three sides of a square. Consequently, their sum, shown as the resultant R, equals the magnitude of one of the phasors.



(b) Express the intensity at the point 1.72 cm from the centerline:

$$I \propto R^2$$

Because $I_0 \propto 9R^2$:

$$\frac{I}{I_0} = \frac{R^2}{9R^2} \Rightarrow I = \frac{I_0}{9}$$

Substitute for I_0 and evaluate I:

$$I = \frac{50.0\,\text{mW/m}^2}{9} = \boxed{5.56\,\text{mW/m}^2}$$

56 ••• In single-slit Fraunhofer diffraction, the intensity pattern (Figure 33-11) consists of a broad central maximum with a sequence of secondary maxima to either side of the central maximum. This intensity is given by $I = I_0\left(\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right)^2$, where ϕ is the phase difference between the wavelets arriving from the opposite edges of the slits. Calculate the values of ϕ for the first three secondary maxima to one side of the central maximum by finding the values of ϕ for which $dI/d\phi$ is equal to zero. Check your results by comparing your answers with approximate values for ϕ of 3π, 5π and 7π. (That these values for ϕ are approximately correct at the secondary intensity maxima is discussed in the discussion surrounding Figure 33-27.)

Picture the Problem We can use the phasor diagram shown in Figure 33-26 to determine the first three values of ϕ that produce secondary intensity maxima. Setting the derivative of Equation 33-19 equal to zero will yield a transcendental equation whose roots are the values of ϕ corresponding to the intensity maxima in the diffraction pattern.

Referring to Figure 33-26 we see that the first subsidiary maximum occurs where:

$$\phi = 3\pi$$

An intensity minimum occurs where:

$$\phi = 4\pi$$

Another intensity maximum occurs where:

$$\phi = 5\pi$$

Thus, secondary intensity maxima occur where:

$$\phi = (2n+1)\pi,\ n = 1, 2, 3, \ldots$$

and the first three secondary intensity maxima are at $\phi = 3\pi, 5\pi,$ and 7π

The intensity in the single-slit diffraction pattern is given by:

$$I = I_0\left(\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right)^2$$

Set the derivative of this expression equal to zero for extreme values (relative minima and maxima):

$$\frac{dI}{d\phi} = 2I_0\left(\frac{\sin\frac{1}{2}\phi}{\frac{1}{2}\phi}\right)\left[\frac{\frac{1}{4}\phi\cos\frac{1}{2}\phi - \frac{1}{2}\sin\frac{1}{2}\phi}{\left(\frac{1}{2}\phi\right)^2}\right] = 0 \text{ for extrema}$$

Simplify to obtain the transcendental equation:

$$\tan\tfrac{1}{2}\phi = \tfrac{1}{2}\phi$$

Solve this equation numerically (use the ″Solver″ function of your calculator or trial-and-error methods) to obtain:

$$\phi = 2.86\pi,\ 4.92\pi,\ \text{and}\ 6.94\pi$$

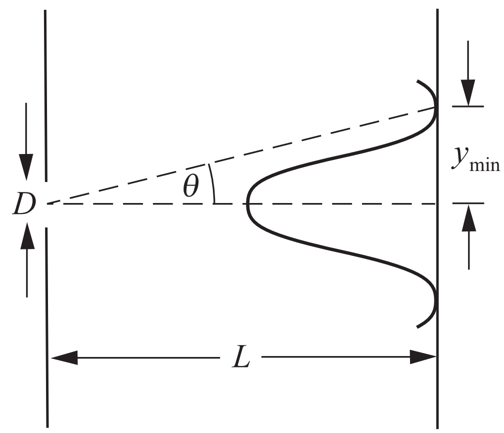
At the three intensity minima $\phi = 2\pi$, 4π, and 6π , and at the three intensity maxima $\phi = 2.86\pi$, 4.92π, and 6.94π. At the intensity maxima $\phi \approx 3\pi$, 5π, and 7π.

Remarks: Note that our results in (*b*) are smaller than the approximate values found in (*a*) by 4.9%, 1.6%, and 0.86% and that the agreement improves as *n* increases.

Diffraction and Resolution

57 • [SSM] Light that has a wavelength equal to 700 nm is incident on a pinhole of diameter 0.100 mm. (*a*) What is the angle between the central maximum and the first diffraction minimum for a Fraunhofer diffraction pattern? (*b*) What is the distance between the central maximum and the first diffraction minimum on a screen 8.00 m away?

Picture the Problem We can use $\theta = 1.22\dfrac{\lambda}{D}$ to find the angle between the central maximum and the first diffraction minimum for a Fraunhofer diffraction pattern and the diagram to the right to find the distance between the central maximum and the first diffraction minimum on a screen 8 m away from the pinhole.



(*a*) The angle between the central maximum and the first diffraction minimum for a Fraunhofer diffraction pattern is given by:

$$\theta = 1.22\frac{\lambda}{D}$$

Substitute numerical values and evaluate θ:

$$\theta = 1.22\left(\frac{700\,\text{nm}}{0.100\,\text{mm}}\right) = \boxed{8.54\,\text{mrad}}$$

(*b*) Referring to the diagram, we see that:

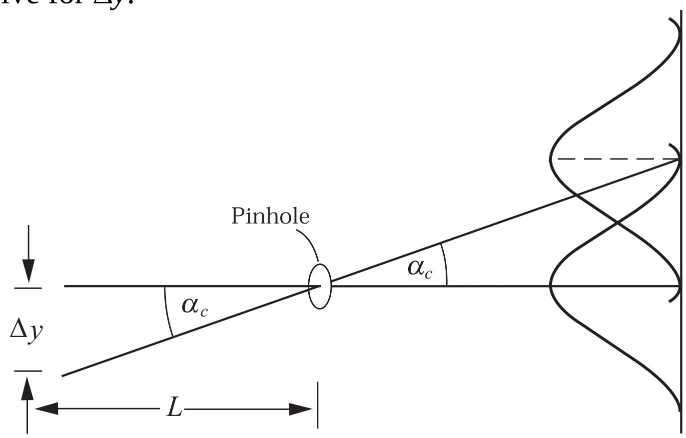
$$y_{\text{min}} = L\tan\theta$$

Substitute numerical values and evaluate y_{min}:

$$y_{\text{min}} = (8.00\,\text{m})\tan(8.54\,\text{mrad}) = \boxed{6.83\,\text{cm}}$$

58 • Two sources of light that both have wavelengths equal to 700 nm are 10.0 m away from the pinhole of Problem 57. How far apart must the sources be for their diffraction patterns to be resolved by Rayleigh's criterion?

Picture the Problem We can apply Rayleigh's criterion to the overlapping diffraction patterns and to the diameter D of the pinhole to obtain an expression that we can solve for Δy.



Rayleigh's criterion is satisfied provided:

$$\alpha_c = 1.22\frac{\lambda}{D}$$

Relate α_c to the separation Δy of the light sources:

$$\alpha_c \approx \frac{\Delta y}{L} \text{ provided } \alpha_c << 1.$$

Equate these expressions to obtain:

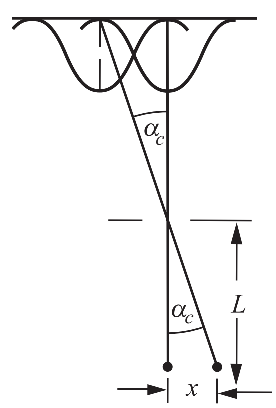
$$\frac{\Delta y}{L} = 1.22\frac{\lambda}{D} \Rightarrow \Delta y = 1.22\frac{\lambda L}{D}$$

Substitute numerical values and evaluate Δy:

$$\Delta y = 1.22\frac{(700\,\text{nm})(10.0\,\text{m})}{0.100\,\text{mm}} = \boxed{8.54\,\text{cm}}$$

59 • Two sources of light that both have wavelengths of 700 nm are separated by a horizontal distance x. They are 5.00 m from a vertical slit of width 0.500 mm. What is the smallest value of x for which the diffraction pattern of the sources can be resolved by Rayleigh's criterion?

Picture the Problem We can use Rayleigh's criterion for slits and the geometry of the diagram to the right showing the overlapping diffraction patterns to express x in terms of λ, L, and the width a of the slit.



Referring to the diagram, relate α_c, L, and x:

$$\alpha_c \approx \frac{x}{L}$$

For slits, Rayleigh's criterion is:

$$\alpha_c = \frac{\lambda}{a}$$

Equate these two expressions to obtain:

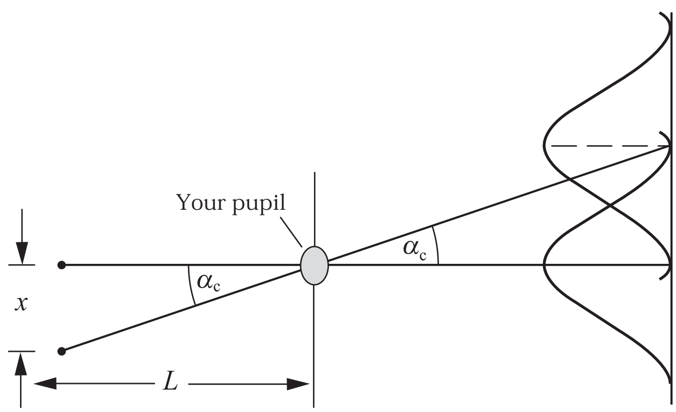
$$\frac{x}{L} = \frac{\lambda}{a} \Rightarrow x = \frac{\lambda L}{a}$$

Substitute numerical values and evaluate x:

$$x = \frac{(700\,\text{nm})(5.00\,\text{m})}{0.500\,\text{mm}} = \boxed{7.00\,\text{mm}}$$

60 •• The ceiling of your lecture hall is probably covered with acoustic tile, which has small holes separated by about 6.0 mm. (*a*) Using light that has a wavelength of 500 nm, how far could you be from this tile and still resolve these holes? Assume the diameter of the pupil of your eye is about 5.0 mm. (*b*) Could you resolve these holes better using red light or using violet light? Explain your answer.

Picture the Problem We can use Rayleigh's criterion for circular apertures and the geometry of the diagram to the right showing the overlapping diffraction patterns to express L in terms of λ, x, and the diameter D of your pupil.



(*a*) Referring to the diagram, relate α_c, L, and x:

$$\alpha_c \approx \frac{x}{L} \text{ provided } \alpha \ll 1$$

For circular apertures, Rayleigh's criterion is:

$$\alpha_c = 1.22\frac{\lambda}{D}$$

Equate these two expressions to obtain:

$$\frac{x}{L} = 1.22\frac{\lambda}{D} \Rightarrow L = \frac{xD}{1.22\lambda}$$

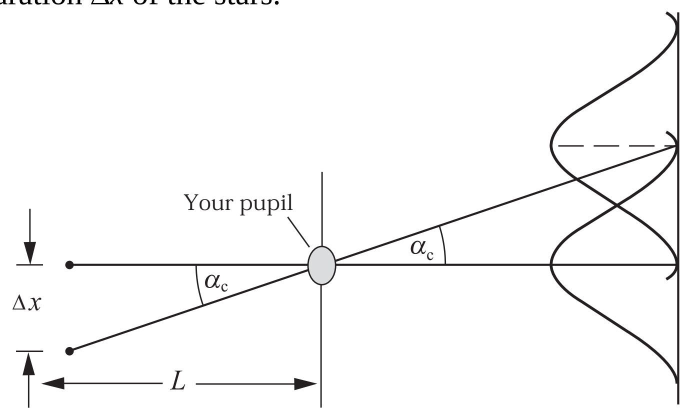
Substitute numerical values and evaluate L:

$$L = \frac{(6.0\,\text{mm})(5.0\,\text{mm})}{1.22(500\,\text{nm})} = \boxed{49\,\text{m}}$$

(b) Because L is inversely proportional to λ, the holes can be resolved better with violet light which has a shorter wavelength. The critical angle for resolution is proportional to the wavelength. Thus, the shorter the wavelength the farther away you can be and still resolve the two images.

61 •• [SSM] The telescope on Mount Palomar has a diameter of 200 in. Suppose a double star were 4.00 light-years away. Under ideal conditions, what must be the minimum separation of the two stars for their images to be resolved using light that has a wavelength equal to 550 nm?

Picture the Problem We can use Rayleigh's criterion for circular apertures and the geometry of the diagram to obtain an expression we can solve for the minimum separation Δx of the stars.



Rayleigh's criterion is satisfied provided:

$$\alpha_c = 1.22\frac{\lambda}{D}$$

Relate α_c to the separation Δx of the light sources:

$$\alpha_c \approx \frac{\Delta x}{L} \text{ because } \alpha_c << 1$$

Equate these expressions to obtain:

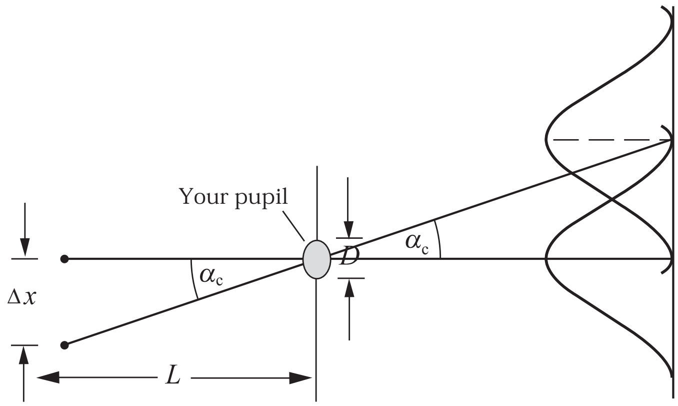
$$\frac{\Delta x}{L} = 1.22\frac{\lambda}{D} \Rightarrow \Delta x = 1.22\frac{\lambda L}{D}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = 1.22\left(\frac{(550\,\text{nm})\left(4c\cdot\text{y}\times\dfrac{9.461\times10^{15}\,\text{m}}{1c\cdot\text{y}}\right)}{200\,\text{in}\times\dfrac{2.54\,\text{cm}}{1\,\text{in}}}\right) = \boxed{5.00\times10^{9}\,\text{m}}$$

62 •• The star Mizar in Ursa Major is a binary system of stars of nearly equal magnitudes. The angular separation between the two stars is 14 seconds of arc. What is the minimum diameter of the pupil that allows resolution of the two stars using light that has a wavelength equal to 550 nm?

Picture the Problem We can use Rayleigh's criterion for circular apertures and the geometry of the diagram to obtain an expression we can solve for the minimum diameter *D* of the pupil that allows resolution of the binary stars.



Rayleigh's criterion is satisfied provided:

$$\alpha_c = 1.22\frac{\lambda}{D} \Rightarrow D = 1.22\frac{\lambda}{\alpha_c}$$

Substitute numerical values and evaluate *D*:

$$D = 1.22\left(\frac{550\,\text{nm}}{14'' \times \frac{1^\circ}{3600''} \times \frac{\pi\,\text{rad}}{180^\circ}}\right)$$
$$= \boxed{9.9\,\text{mm}} \approx 1\,\text{cm}$$

Diffraction Gratings

63 • **[SSM]** A diffraction grating that has 2000 slits per centimeter is used to measure the wavelengths emitted by hydrogen gas. (*a*) At what angles in the first-order spectrum would you expect to find the two violet lines that have wavelengths of 434 nm and 410 nm? (*b*) What are the angles if the grating has 15 000 slits per centimeter?

Picture the Problem We can solve $d\sin\theta = m\lambda$ for θ with m = 1 to express the location of the first-order maximum as a function of the wavelength of the light.

(*a*) The interference maxima in a diffraction pattern are at angles θ given by:

$$d\sin\theta = m\lambda$$

where *d* is the separation of the slits and *m* = 0, 1, 2, …

Solve for the angular location θ_m of the maxima :

$$\theta_m = \sin^{-1}\left(\frac{m\lambda}{d}\right)$$

Relate the number of slits N per centimeter to the separation d of the slits:

$$N = \frac{1}{d}$$

Substitute for d to obtain:

$$\theta_m = \sin^{-1}(mN\lambda) \qquad (1)$$

Evaluate θ for λ = 434 nm and m =1:

$$\theta_1 = \sin^{-1}\left[\left(2000\,\text{cm}^{-1}\right)(434\,\text{nm})\right] = \boxed{86.9\,\text{mrad}}$$

Evaluate θ for λ = 410 nm and m = 1:

$$\theta_1 = \sin^{-1}\left[\left(2000\,\text{cm}^{-1}\right)(410\,\text{nm})\right] = \boxed{82.1\,\text{mrad}}$$

(b) Use equation (1) to evaluate θ for λ = 434 nm and m = 1:

$$\theta_1 = \sin^{-1}\left[\left(15000\,\text{cm}^{-1}\right)(434\,\text{nm})\right] = \boxed{709\,\text{mrad}}$$

Evaluate θ for λ = 410 nm and m = 1:

$$\theta_1 = \sin^{-1}\left[\left(15000\,\text{cm}^{-1}\right)(410\,\text{nm})\right] = \boxed{662\,\text{mrad}}$$

64 • Using a diffraction grating that has 2000 lines per centimeter, two other lines in the first-order hydrogen spectrum are found at angles of 9.72×10^{-2} rad and 1.32×10^{-1} rad. What are the wavelengths of these lines?

Picture the Problem We can solve $d\sin\theta = m\lambda$ for λ with m = 1 to express the location of the first-order maximum as a function of the angles at which the first-order images are found.

The interference maxima in a diffraction pattern are at angles θ given by:

$$d\sin\theta = m\lambda \Rightarrow \lambda = \frac{d\sin\theta}{m}$$

where d is the separation of the slits and m = 0, 1, 2, …

Relate the number of slits N per centimeter to the separation d of the slits:

$$N = \frac{1}{d}$$

Let $m = 1$ and substitute for d to obtain:

$$\lambda = \frac{\sin\theta}{N}$$

Substitute numerical values and evaluate λ_1 for $\theta_1 = 9.72\times10^{-2}$ rad:

$$\lambda_1 = \frac{\sin\left(9.72\times10^{-2}\text{ rad}\right)}{2000\text{ cm}^{-1}} = \boxed{485\text{ nm}}$$

Substitute numerical values and evaluate λ_1 for $\theta_2 = 1.32\times10^{-1}$ rad:

$$\lambda_1 = \frac{\sin\left(1.32\times10^{-1}\text{ rad}\right)}{2000\text{ cm}^{-1}} = \boxed{658\text{ nm}}$$

65 • The colors of many butterfly wings and beetle carapaces are due to effects of diffraction. The *Morpho* butterfly has structural elements on its wings that effectively act as a diffraction grating with spacing 880 nm. At what angle will the first diffraction maximum occur for normally incident light diffracted by the butterfly's wings? Assume the light is blue with a wavelength of 440 nm.

Picture the Problem We can use the grating equation to find the angle at which normally incident blue light will be diffracted by the butterfly's wings.

The grating equation is:

$d\sin\theta = m\lambda$, where m = 1, 2, 3, …

Solve for θ to obtain:

$$\theta = \sin^{-1}\left[\frac{m\lambda}{d}\right]$$

Substitute numerical values and evaluate θ_1:

$$\theta = \sin^{-1}\left[\frac{(1)(440\text{ nm})}{880\text{ nm}}\right] = \boxed{30.0^\circ}$$

66 •• A diffraction grating that has 2000 slits per centimeter is used to analyze the spectrum of mercury. (*a*) Find the angular separation in the first-order spectrum of the two lines of wavelength 579 nm and 577 nm. (*b*) How wide must the beam on the grating be for these lines to be resolved?

Picture the Problem We can use the grating equation to find the angular separation of the first-order spectrum of the two lines. In Part (*b*) we can apply the definition of the resolving power of the grating to find the width of the grating that must be illuminated for the lines to be resolved.

(*a*) Express the angular separation in the first-order spectrum of the two lines:

$$\Delta\theta = \theta_{579} - \theta_{577}$$

Solve the grating equation for θ:

$$\theta = \sin^{-1}\left(\frac{m\lambda}{d}\right)$$

Substitute for θ_{579} and θ_{577} to obtain:

$$\Delta\theta = \sin^{-1}\left[\frac{m(579\,\text{nm})}{\frac{1}{2000\,\text{cm}^{-1}}}\right] - \sin^{-1}\left[\frac{m(577\,\text{nm})}{\frac{1}{2000\,\text{cm}^{-1}}}\right] = \sin^{-1}[0.1158m] - \sin^{-1}[0.1154m]$$

For $m = 1$:

$$\Delta\theta = \sin^{-1}[0.1158m] - \sin^{-1}[0.1154m] = 6.65° - 6.63° = \boxed{0.02°}$$

(*b*) The width of the beam necessary for these lines to be resolved is given by:

$$w = Nd \qquad (1)$$

Relate the resolving power of the diffraction grating to the number of slits *N* that must be illuminated in order to resolve these wavelengths in the *m*th order:

$$\frac{\lambda}{\Delta\lambda} = mN$$

For $m = 1$:

$$N = \frac{\lambda}{\Delta\lambda}$$

Substitute for *N* in equation (1) to obtain:

$$w = \frac{\lambda d}{\Delta\lambda}$$

Letting λ be the average of the two wavelengths, substitute numerical values and evaluate *w*:

$$w = \frac{(578\,\text{nm})\left(\frac{1}{2000\,\text{cm}^{-1}}\right)}{2\,\text{nm}} = \boxed{1\text{mm}}$$

67 •• [SSM] A diffraction grating that has 4800 lines per centimeter is illuminated at normal incidence with white light (wavelength range of 400 nm to 700 nm). How many orders of spectra can one observe in the transmitted light? Do any of these orders overlap? If so, describe the overlapping regions.

Picture the Problem We can use the grating equation $d\sin\theta = m\lambda, m = 1, 2, 3, \ldots$ to express the order number in terms of the slit separation *d*, the wavelength of the light λ, and the angle θ.

The interference maxima in the diffraction pattern are at angles θ given by:

$$d\sin\theta = m\lambda \Rightarrow m = \frac{d\sin\theta}{\lambda}$$

where m = 1, 2, 3, …

If one is to see the complete spectrum, it must be true that:

$$\sin\theta \le 1 \Rightarrow m \le \frac{d}{\lambda}$$

Evaluate m_{max}:

$$m_{max} = \frac{\dfrac{1}{4800\,\text{cm}^{-1}}}{\lambda_{max}} = \frac{\dfrac{1}{4800\,\text{cm}^{-1}}}{700\,\text{nm}} = 2.98$$

Because m_{max} = 2.98, one can see the complete spectrum only for m = 1 and 2.

Express the condition for overlap:

$$m_1\lambda_1 \ge m_2\lambda_2$$

One can see the complete spectrum for only the first and second order spectra. That is, only for m = 1 and 2. Because 700 nm < 2 × 400 nm, there is no overlap of the second-order spectrum into the first-order spectrum; however, there is overlap of long wavelengths in the second order with short wavelengths in the third-order spectrum.

68 •• A square diffraction grating that has an area of 25.0 cm^2 has a resolution of 22 000 in the fourth order. At what angle should you look to see a wavelength of 510 nm in the fourth order?

Picture the Problem We can use the grating equation and the resolving power of the grating to derive an expression for the angle at which you should look to see a wavelength of 510 nm in the fourth order.

The interference maxima in the diffraction pattern are at angles θ given by:

$$d\sin\theta = m\lambda, \quad \text{where } m = 1, 2, 3, \ldots \qquad (1)$$

The resolving power R is given by:

$$R = mN$$

where N is the number of slits and m is the order number.

Relate d to the width w of the grating:

$$d = \frac{w}{N}$$

Substitute for N and simplify to obtain:

$$d = \frac{mw}{R}$$

Substitute for d in equation (1) to obtain:

$$\frac{mw}{R}\sin\theta = m\lambda \Rightarrow \theta = \sin^{-1}\left(\frac{R\lambda}{w}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{(22{,}000)(510\,\text{nm})}{5.00\,\text{cm}}\right] = \boxed{13.0°}$$

69 •• Sodium light that has a wavelength equal to 589 nm falls normally on a 2.00-cm-square diffraction grating ruled with 4000 lines per centimeter. The Fraunhofer diffraction pattern is projected onto a screen a distance of 1.50 m from the grating by a 1.50-m-focal-length lens that is placed immediately in front of the grating. Find (*a*) the distance of the first and second order intensity maxima from the central intensity maximum, (*b*) the width of the central maximum, and (*c*) the resolution in the first order. (Assume the entire grating is illuminated.)

Picture the Problem The distance on the screen to the *m*th bright fringe can be found using $d\sin\theta = m\lambda$ (where d is the slit separation and m = 0, 1, 2, …) and the geometry of the grating and projection screen. We can use $\theta_{\text{min}} = \lambda/Nd = \Delta y/2L$ to find the width of the central maximum and $R = mN$, where N is the number of slits in the grating, to find the resolving power in the first order.

(*a*) The angle θ at which maxima occur is related to the slit separation d, the wavelength of the incident light λ, and the order number m according to:

$$d\sin\theta = m\lambda \qquad (1)$$

where m = 0, 1, 2, … .

θ is also related to the distance to the screen L and the positions of the intensity maxima y_m:

$$\sin\theta = \frac{y_m}{\sqrt{L^2 + y_m^2}}$$

Substituting for $\sin\theta$ in equation (1) yields:

$$\frac{dy_m}{\sqrt{L^2 + y_m^2}} = m\lambda \Rightarrow y_m = \frac{m\lambda L}{\sqrt{d^2 - m^2\lambda^2}}$$

Substituting numerical values yields:

$$y_m = \frac{m(589\,\text{nm})(1.50\,\text{m})}{\sqrt{\left(\frac{1.00\,\text{cm}}{4000}\right)^2 - m^2(589\,\text{nm})^2}}$$

Evaluate this expression for $m = 1$ and $m = 2$ to obtain:

$$y_1 = \boxed{36.4\,\text{cm}} \text{ and } y_2 = \boxed{80.1\,\text{cm}}$$

(*b*) The angle $\theta_{\min}$ that locates the first minima in the diffraction pattern is given by:

$$\theta_{\min} = \frac{\lambda}{Nd} = \frac{\Delta y}{2L} \Rightarrow \Delta y = \frac{2L\lambda}{Nd}$$

where Δy is the width of the central maximum.

Substitute numerical values and evaluate Δy:

$$\Delta y = \frac{2(1.50\,\text{m})(589\,\text{nm})}{(8000\,\text{lines})\left(\dfrac{1}{4000\,\text{cm}^{-1}}\right)} = \boxed{88.4\,\mu\text{m}}$$

(*c*) The resolving power R in the mth order is given by:

$$R = mN$$

Substitute numerical values and evaluate R:

$$R = (1)(8000) = \boxed{8000}$$

70 •• The spectrum of neon is exceptionally rich in the visible region. Among the many lines are two lines at wavelengths of 519.313 nm and 519.322 nm. If light from a neon discharge tube is normally incident on a transmission grating with 8400 lines per centimeter and the spectrum is observed in second order, what must be the width of the grating that is illuminated, so that these two lines can be resolved?

Picture the Problem The width of the grating w is the product of its number of lines N and the separation of its slits d. Because the resolution of the grating is a function of the average wavelength, the difference in the wavelengths, and the order number, we can express w in terms of these quantities.

Express the width w of the grating as a function of the number of lines N and the slit separation d:

$$w = Nd$$

The resolving power R of the grating is given by:

$$R = \frac{\lambda}{\Delta\lambda} = mN \Rightarrow N = \frac{\lambda}{m\Delta\lambda}$$

Substitute for N in the expression for w to obtain:

$$w = \frac{\lambda d}{m\Delta\lambda}$$

Letting λ be the average of the given wavelengths, substitute numerical values and evaluate w:

$$w=\frac{\frac{1}{2}(519.313\,\text{nm}+519.322\,\text{nm})\left(\dfrac{1}{8400\,\text{cm}^{-1}}\right)}{2(519.322\,\text{nm}-519.313\,\text{nm})}=\boxed{3\,\text{cm}}$$

71 •• [SSM] Mercury has several stable isotopes, among them ^{198}Hg and ^{202}Hg. The strong spectral line of mercury, at about 546.07 nm, is a composite of spectral lines from the various mercury isotopes. The wavelengths of this line for ^{198}Hg and ^{202}Hg are 546.07532 nm and 546.07355 nm, respectively. What must be the resolving power of a grating capable of resolving these two isotopic lines in the third-order spectrum? If the grating is illuminated over a 2.00-cm-wide region, what must be the number of lines per centimeter of the grating?

Picture the Problem We can use the expression for the resolving power of a grating to find the resolving power of the grating capable of resolving these two isotopic lines in the third-order spectrum. Because the total number of the slits of the grating N is related to width w of the illuminated region and the number of lines per centimeter of the grating and the resolving power R of the grating, we can use this relationship to find the number of lines per centimeter of the grating.

The resolving power of a diffraction grating is given by:

$$R=\frac{\lambda}{|\Delta\lambda|}=mN \qquad (1)$$

Substitute numerical values and evaluate R:

$$R=\frac{546.07532}{|546.07532-546.07355|}=3.0852\times10^{5}=\boxed{3.09\times10^{5}}$$

Express n, be the number of lines per centimeter of the grating, in terms of the total number of slits N of the grating and the width w of the grating:

$$n=\frac{N}{w}$$

From equation (1) we have:

$$N=\frac{R}{m}$$

Substitute for N to obtain:

$$n=\frac{R}{mw}$$

Substitute numerical values and evaluate n:

$$n = \frac{3.0852\times10^{5}}{(3)(2.00\,\text{cm})} = \boxed{5.14\times10^{4}\ \text{cm}^{-1}}$$

72 ••• A diffraction grating has n lines per unit length. Show that the angular separation ($\Delta\theta$) of two lines of wavelengths λ and $\lambda + \Delta\lambda$ is approximately $\Delta\theta = \Delta\lambda \Big/ \sqrt{\frac{1}{n^2m^2} - \lambda^2}$ where m is the order number.

Picture the Problem We can differentiate the grating equation implicitly and approximate $d\theta/d\lambda$ by $\Delta\theta/\Delta\lambda$ to obtain an expression $\Delta\theta$ as a function of m, n, $\Delta\lambda$, and $\cos\theta$. We can use the Pythagorean identity $\sin^2\theta + \cos^2\theta = 1$ and the grating equation to write $\cos\theta$ in terms of n, m, and λ. Making these substitutions will yield the given equation.

The grating equation is:

$$d\sin\theta = m\lambda,\ m = 0, 1, 2, \ldots \qquad (1)$$

Differentiate both sides of this equation with respect to λ:

$$\frac{d}{d\lambda}(d\sin\theta) = \frac{d}{d\lambda}(m\lambda)$$

or

$$d\cos\theta\frac{d\theta}{d\lambda} = m$$

Because $n = 1/d$:

$$\cos\theta\frac{d\theta}{d\lambda} = nm \Rightarrow n = \frac{1}{m}\cos\theta\frac{d\theta}{d\lambda}$$

Approximate $d\theta/d\lambda$ by $\Delta\theta/\Delta\lambda$:

$$n = \frac{1}{m}\frac{\Delta\theta}{\Delta\lambda}\cos\theta$$

Solving for $\Delta\theta$ yields:

$$\Delta\theta = \frac{nm\Delta\lambda}{\cos\theta}$$

Substitute for $\cos\theta$ to obtain:

$$\Delta\theta = \frac{nm\Delta\lambda}{\sqrt{1-\sin^2\theta}}$$

From equation (1):

$$\sin\theta = \frac{m\lambda}{d} = nm\lambda$$

Substituting for $\sin\theta$ yields:

$$\Delta\theta = \frac{nm\Delta\lambda}{\sqrt{1-n^2m^2\lambda^2}}$$

Simplify by dividing the numerator and denominator by *nm* to obtain:

$$\Delta\theta = \frac{\Delta\lambda}{\frac{1}{nm}\sqrt{1-n^2m^2\lambda^2}} = \frac{\Delta\lambda}{\sqrt{\frac{1-n^2m^2\lambda^2}{n^2m^2}}} = \boxed{\frac{\Delta\lambda}{\sqrt{\frac{1}{n^2m^2}-\lambda^2}}}$$

73 ••• [SSM] For a diffraction grating in which all the surfaces are normal to the incident radiation, most of the energy goes into the zeroth order, which is useless from a spectroscopic point of view, since in zeroth order all the wavelengths are at 0º. Therefore, modern reflection gratings have shaped, or *blazed*, grooves, as shown in Figure 33-45. This shifts the specular reflection, which contains most of the energy, from the zeroth order to some higher order. (*a*) Calculate the *blaze angle* ϕ_m in terms of the groove separation *d*, the wavelength λ, and the order number *m* in which specular reflection is to occur for $m = 1, 2, \ldots$. (*b*) Calculate the proper blaze angle for the specular reflection to occur in the second order for light of wavelength 450 nm incident on a grating with 10 000 lines per centimeter.

Picture the Problem We can use the grating equation and the geometry of the grating to derive an expression for ϕ_m in terms of the order number *m*, the wavelength of the light λ, and the groove separation *d*.

(*a*) Because $\theta_i = \theta_r$, application of the grating equation yields:

$$d\sin(2\theta_i) = m\lambda, \quad \text{where } m = 0, 1, 2, \ldots \qquad (1)$$

Because ϕ and θ_i have their left and right sides mutually perpendicular:

$$\theta_i = \phi_m$$

Substitute for θ_i to obtain:

$$d\sin(2\phi_m) = m\lambda$$

Solving for ϕ_m yields:

$$\phi_m = \boxed{\tfrac{1}{2}\sin^{-1}\left(m\frac{\lambda}{d}\right)}$$

(*b*) For $m = 2$:

$$\phi_2 = \tfrac{1}{2}\sin^{-1}\left(2\frac{450\,\text{nm}}{\frac{1}{10{,}000\,\text{cm}^{-1}}}\right) = \boxed{32.1^\circ}$$

74 ••• In this problem, you will derive the relation $R = \lambda/|\Delta\lambda| = mN$ (Equation 33-27) for the resolving power of a diffraction grating containing *N* slits separated by a distance *d*. To do this, you will calculate the angular

separation between the intensity maximum and intensity minimum for some wavelength λ and set it equal to the angular separation of the mth-order maximum for two nearby wavelengths. (a) First show that the phase difference ϕ between the waves from two adjacent slits is given by $\phi = \dfrac{2\pi d}{\lambda}\sin\theta$. ($b$) Next differentiate this expression to show that a small change in angle $d\theta$ results in a change in phase of $d\phi$ given by $d\phi = \dfrac{2\pi d}{\lambda}\cos\theta\, d\theta$. ($c$) Then for N slits, the angular separation between an interference maximum and an interference minimum corresponds to a phase change of $d\phi = 2\pi/N$. Use this to show that the angular separation $d\theta$ between the intensity maximum and intensity minimum for some wavelength λ is given by $d\theta = \dfrac{\lambda}{Nd\cos\theta}$. ($d$) Next use the fact that the angle of the mth-order interference maximum for wavelength λ is specified by $d\sin\theta = m\lambda$ (Equation 33-26). Compute the differential of each side of this equation to show that angular separation of the mth-order maximum for two nearly equal wavelengths differing by $d\lambda$ is given by $d\theta = \dfrac{m\,d\lambda}{d\cos\theta}$. ($e$) According to Rayleigh's criterion, two wavelengths will be resolved in the mth order if the angular separation of the wavelengths, given by the Part (d) result, equals the angular separation of the interference maximum and the interference minimum given by the Part (c) result. Use this to arrive at $R = \lambda/|\Delta\lambda| = mN$ (Equation 33-27) for the resolving power of a grating.

Picture the Problem We can follow the procedure outlined in the problem statement to obtain $R = \lambda/|\Delta\lambda| = mN$.

(a) Express the relationship between the phase difference ϕ and the path difference Δr:

$$\frac{\phi}{2\pi} = \frac{\Delta r}{\lambda} \Rightarrow \phi = \frac{2\pi\Delta r}{\lambda}$$

Because $\Delta r = d\sin\theta$:

$$\phi = \boxed{\frac{2\pi d}{\lambda}\sin\theta}$$

(b) Differentiate this expression with respect to θ to obtain:

$$\frac{d\phi}{d\theta} = \frac{d}{d\theta}\left[\frac{2\pi d}{\lambda}\sin\theta\right] = \frac{2\pi d}{\lambda}\cos\theta$$

Solve for $d\phi$:

$$d\phi = \boxed{\frac{2\pi d}{\lambda}\cos\theta\, d\theta}$$

(c) From Part (b):

$$d\theta = \frac{\lambda d\phi}{2\pi d\cos\theta}$$

Substitute $2\pi/N$ for $d\phi$ to obtain:

$$d\theta = \boxed{\frac{\lambda}{Nd\cos\theta}}$$

(*d*) Equation 33-26 is:

$$d\sin\theta = m\lambda,\ m = 0, 1, 2, \ldots$$

Differentiate this expression implicitly with respect to λ to obtain:

$$\frac{d}{d\lambda}[d\sin\theta] = \frac{d}{d\lambda}[m\lambda]$$

or

$$d\cos\theta\frac{d\theta}{d\lambda} = m$$

Solve for $d\theta$ to obtain:

$$d\theta = \boxed{\frac{md\lambda}{d\cos\theta}}$$

(*e*) Equate the two expressions for $d\theta$ obtained in (*c*) and (*d*):

$$\frac{\lambda}{Nd\cos\theta} = \frac{md\lambda}{d\cos\theta}$$

Approximating $d\lambda$ by $\Delta\lambda$ and allowing for the possibility that $\Delta\lambda < 0$ yields:

$$\frac{\lambda}{Nd\cos\theta} = \frac{m|\Delta\lambda|}{d\cos\theta}$$

Solving for $R = \lambda/\Delta\lambda$ yields:

$$R = \boxed{\frac{\lambda}{|\Delta\lambda|} = mN}$$

General Problems

75 • **[SSM]** Naturally occurring coronas (brightly colored rings) are sometimes seen around the Moon or the Sun when viewed through a thin cloud. (Warning: When viewing a sun corona, be sure that the entire sun is blocked by the edge of a building, a tree, or a traffic pole to safeguard your eyes.) These coronas are due to diffraction of light by small water droplets in the cloud. A typical angular diameter for a coronal ring is about 10º. From this, estimate the size of the water droplets in the cloud. Assume that the water droplets can be modeled as opaque disks with the same radius as the droplet, and that the Fraunhofer diffraction pattern from an opaque disk is the same as the pattern from an aperture of the same diameter. (This last statement is known as *Babinet's principle*.)

Picture the Problem We can use $\sin\theta = 1.22\lambda/D$ to relate the diameter D of the opaque-disk water droplets to the angular diameter θ of a coronal ring and to the wavelength of light. We'll assume a wavelength of 500 nm.

The angle θ subtended by the first diffraction minimum is related to the wavelength λ of light and the diameter D of the opaque-disk water droplet:

$$\sin\theta = 1.22\frac{\lambda}{D}$$

Because of the great distance to the cloud of water droplets, $\theta << 1$ and:

$$\theta \approx 1.22\frac{\lambda}{D} \Rightarrow D = \frac{1.22\lambda}{\theta}$$

Substitute numerical values and evaluate D:

$$D = \frac{1.22(500\,\text{nm})}{10°\times\frac{\pi\,\text{rad}}{180°}} = \boxed{3.5\,\mu\text{m}}$$

76 • An artificial corona (see Problem 75) can be made by placing a suspension of polystyrene microspheres in water. Polystyrene microspheres are small, uniform spheres made of plastic with an index of refraction equal to 1.59. Assuming that the water has an index of refractive equal to 1.33, what is the angular diameter of such an artificial corona if 5.00-μm-diameter particles are illuminated by light from a helium–neon laser with wavelength in air of 632.8 nm?

Picture the Problem We can use $\sin\theta = 1.22\lambda_n/D$ to relate the diameter D of a microsphere to the angular diameter θ of a coronal ring and to the wavelength of light in water.

The angle θ subtended by the first diffraction minimum is related to the wavelength λ_n of light in water and the diameter D of the microspheres:

$$\sin\theta = 1.22\frac{\lambda_n}{D} = 1.22\frac{\lambda}{nD}$$

Because $\theta << 1$:

$$\theta \approx 1.22\frac{\lambda}{nD}$$

Substitute numerical values and evaluate θ:

$$\theta \approx \frac{(1.22)(632.8\,\text{nm})}{(1.33)(5.00\,\mu\text{m})} = 0.116\,\text{rad}$$

$$= \boxed{6.65°}$$

77 • Coronas (see Problem 74) can be caused by pollen grains, typically of birch or pine. Such grains are irregular in shape, but they can be treated as if they had an average diameter of about 25 μm. What is the angular diameter (in degrees) of the corona for blue light? What is the diameter (in degrees) of the corona for red light?

Picture the Problem We can use $\sin\theta = 1.22\lambda/D$ to relate the diameter D of a pollen grain to the angular diameter θ of a coronal ring and to the wavelength of light. We'll assume a wavelength of 450 nm for blue light and 650 nm for red light.

The angle α subtended by the first diffraction intensity minima is related to the wavelength λ of light and to the diameter D of the microspheres:

$$\sin\alpha = 1.22\frac{\lambda}{D}$$

or, because $\alpha = \frac{1}{2}\theta$ where θ is the angular diameter of the coronal ring,

$$\sin\tfrac{1}{2}\theta = 1.22\frac{\lambda}{D}$$

Because $\theta << 1$, $\sin\theta \approx \theta$ and:

$$\tfrac{1}{2}\theta \approx 1.22\frac{\lambda}{D} \Rightarrow \theta \approx 2.44\frac{\lambda}{D}$$

Substitute numerical values and evaluate θ for red light:

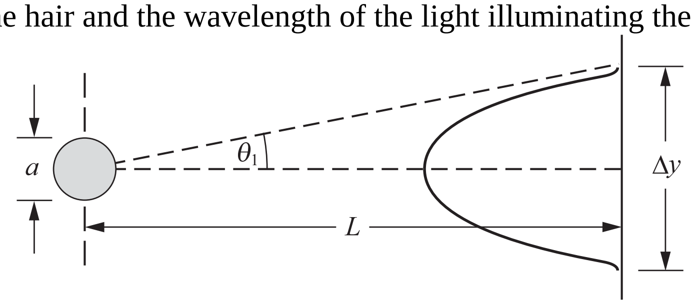
$$\theta_{\text{red}} \approx \frac{2.44(650\,\text{nm})}{25\,\mu\text{m}} = 6.344\times10^{-2}\text{ rad} = \boxed{3.6°}$$

Substitute numerical values and evaluate θ for blue light:

$$\theta_{\text{blue}} \approx \frac{2.44(450\,\text{nm})}{25\,\mu\text{m}} = 4.392\times10^{-2}\text{ rad} = \boxed{2.5°}$$

78 • Light from a He-Ne laser (632.8 nm wavelength) is directed upon a human hair, in an attempt to measure its diameter by examining the diffraction pattern. The hair is mounted in a frame 7.5 m from a wall, and the central diffraction maximum is measured to be 14.6 cm wide. What is the diameter of the hair? (The diffraction pattern of a hair with diameter d is the same as the diffraction pattern of a single slit with width $a = d$. See Babinet's principle, Problem 75.)

Picture the Problem The diagram shows the hair whose diameter $d = a$, the screen a distance L from the hair, and the separation Δy of the first diffraction peak from the center. We can use the geometry of the experiment to relate Δy to L and a and the condition for diffraction maxima to express θ_1 in terms of the diameter of the hair and the wavelength of the light illuminating the hair.



Relate θ to Δy:

$$\tan\theta = \frac{\frac{1}{2}\Delta y}{L} \Rightarrow \theta = \tan^{-1}\left(\frac{\Delta y}{2L}\right)$$

Diffraction maxima occur where:

$$a\sin\theta = \left(m+\tfrac{1}{2}\right)\lambda \Rightarrow a = \frac{\left(m+\frac{1}{2}\right)\lambda}{\sin\theta}$$

where m = 1, 2, 3, …

Substituting for θ yields:

$$a = \frac{\left(m+\frac{1}{2}\right)\lambda}{\sin\left[\tan^{-1}\left(\frac{\Delta y}{2L}\right)\right]}$$

Substitute numerical values and evaluate a for m = 1:

$$a = \frac{\left(1+\frac{1}{2}\right)(632.8\,\text{nm})}{\sin\left[\tan^{-1}\left(\frac{14.6\,\text{cm}}{2(7.5\,\text{m})}\right)\right]} = \boxed{98\,\mu\text{m}}$$

79 • **[SSM]** A long, narrow horizontal slit lies 1.00 μm above a plane mirror, which is in the horizontal plane. The interference pattern produced by the slit and its image is viewed on a screen 1.00 m from the slit. The wavelength of the light is 600 nm. (*a*) Find the distance from the mirror to the first maximum. (*b*) How many dark bands per centimeter are seen on the screen?

Picture the Problem We can apply the condition for constructive interference to find the angular position of the first maximum on the screen. Note that, due to reflection, the wave from the image is 180° out of phase with that from the source.

(*a*) Because $y_0 << L$, the distance from the mirror to the first maximum is given by:

$$y_0 = L\theta_0 \qquad (1)$$

Express the condition for constructive interference:

$$d\sin\theta = \left(m+\tfrac{1}{2}\right)\lambda$$

where m = 0, 1, 2, …

Solving for θ yields:

$$\theta = \sin^{-1}\left[\left(m+\tfrac{1}{2}\right)\frac{\lambda}{d}\right]$$

For the first maximum, m = 0 and:

$$\theta_0 = \sin^{-1}\left[\frac{\lambda}{2d}\right]$$

Substitute in equation (1) to obtain:

$$y_0 = L\sin^{-1}\left[\frac{\lambda}{2d}\right]$$

Because the image of the slit is as far behind the mirror's surface as the slit is in front of it, $d = 2.00\ \mu\text{m}$. Substitute numerical values and evaluate y_0:

$$y_0 = (1.00\,\text{m})\sin^{-1}\left[\frac{600\,\text{nm}}{2(2.00\,\mu\text{m})}\right]$$
$$= \boxed{15.1\,\text{cm}}$$

(*b*) The separation of the fringes on the screen is given by:

$$\Delta y = \frac{\lambda L}{d}$$

The number of dark bands per unit length is the reciprocal of the fringe separation:

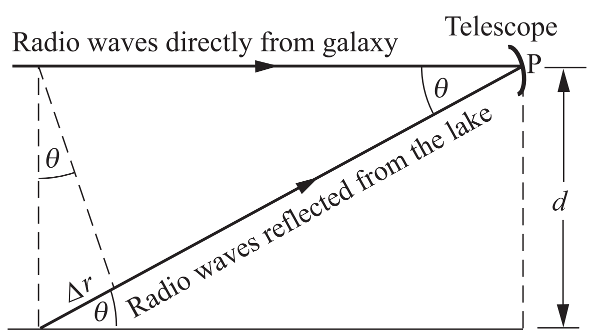
$$n = \frac{1}{\Delta y} = \frac{d}{\lambda L}$$

Substitute numerical values and evaluate n:

$$n = \frac{2.00\,\mu\text{m}}{(600\,\text{nm})(1.00\,\text{m})} = \boxed{3.33\ \text{m}^{-1}}$$

80 • A radio telescope is situated at the edge of a lake. The telescope is looking at light from a radio galaxy that is just rising over the horizon. If the height of the antenna is 20 m above the surface of the lake, at what angle above the horizon will the radio galaxy be when the telescope is centered in the first intensity interference maximum of the radio waves? Assume the wavelength of the radio waves is 20 cm. *Hint: The interference is caused by the light reflecting off the lake and remember that this reflection will result in a 180º phase shift.*

Picture the Problem The radio waves from the galaxy reach the telescope by two paths; one coming directly from the galaxy and the other reflected from the surface of the lake. The radio waves reflected from the surface of the lake are phase shifted 180°, relative to the radio waves reaching the telescope directly, by reflection from the surface of the lake. We can use the condition for constructive interference of two waves to find the angle above the horizon at which the radio waves from the galaxy will interfere constructively.



Because the reflected radio waves are phase shifted by 180°, the condition for constructive interference at point P is:

$$\Delta r = \left(m + \tfrac{1}{2}\right)\lambda$$
where $m = 0, 1, 2, \ldots$

Referring to the figure, note that:

$$\sin\theta \approx \frac{\Delta r}{d} \Rightarrow \theta = \sin^{-1}\left[\frac{\Delta r}{d}\right]$$

Substitute for Δr to obtain:

$$\theta = \sin^{-1}\left[\frac{\left(m + \frac{1}{2}\right)\lambda}{d}\right]$$

Noting that $m = 0$ for the first interference maximum, substitute numerical values and evaluate θ_0:

$$\theta_0 = \sin^{-1}\left[\frac{\frac{1}{2}(20\,\text{cm})}{20\,\text{m}}\right] = 5.00\times10^{-3}\ \text{rad}$$
$$= \boxed{0.29°}$$

81 • The diameter of the radio telescope at Arecibo, Puerto Rico, is 300 m. What is the smallest angular separation of two objects that this telescope can detect when it is tuned to detect microwaves of 3.2-cm wavelength?

Picture the Problem The resolving power of a telescope is the ability of the instrument to resolve two objects that are close together. Hence we can use Rayleigh's criterion to find the resolving power of the Arecibo telescope.

Rayleigh's criterion for resolution is:

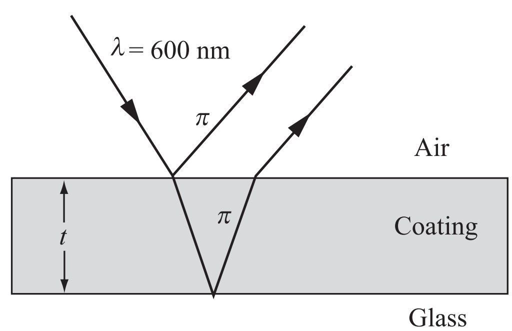
$$\alpha_c = 1.22\frac{\lambda}{D}$$

Substitute numerical values and evaluate α_c:

$$\alpha_c = 1.22\left(\frac{3.2\,\text{cm}}{300\,\text{m}}\right) = \boxed{0.13\,\text{mrad}}$$

82 •• A thin layer of a transparent material that has an index of refraction of 1.30 is used as a nonreflective coating on the surface of glass that has an index of refraction of 1.50. What should the minimum thickness of the material be for the material to be nonreflecting for light that has a wavelength 600 nm?

Picture the Problem Note that reflection at both surfaces involves a phase shift of π rad. We can apply the condition for destructive interference to find the thickness t of the nonreflective coating.



The condition for destructive interference is:

$$2t = \left(m+\tfrac{1}{2}\right)\lambda_{\text{coating}} = \left(m+\tfrac{1}{2}\right)\frac{\lambda_{\text{air}}}{n_{\text{coating}}}$$

Solve for t to obtain:

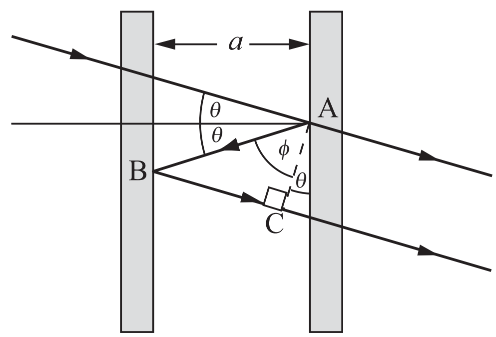
$$t = \left(m+\tfrac{1}{2}\right)\frac{\lambda_{\text{air}}}{2n_{\text{coating}}}$$

Evaluate t for $m = 0$:

$$t = \left(\tfrac{1}{2}\right)\frac{600\,\text{nm}}{2(1.30)} = \boxed{115\,\text{nm}}$$

83 •• [SSM] A *Fabry–Perot interferometer* (Figure 33-47) consists of two parallel, half-silvered mirrors that face each other and are separated by a small distance a. A half-silvered mirror is one that transmits 50% of the incident intensity and reflects 50% of the incident intensity. Show that when light is incident on the interferometer at an angle of incidence θ, the transmitted light will have maximum intensity when $2a = m\lambda/\cos\,\theta$.

Picture the Problem The *Fabry-Perot interferometer* is shown in the figure. For constructive interference in the transmitted light the path difference must be an integral multiple of the wavelength of the light. This path difference can be found using the geometry of the interferometer.



For constructive interference we require that:

$$\Delta r = m\lambda, m = 0, 1, 2, \ldots \qquad (1)$$

The path difference between the two rays that emerge from the interferometer is given by:

$$\Delta r = \text{AB} + \text{BC} = \frac{a}{\cos\theta} + \text{AB}\sin\phi$$

From the geometry of the interferometer:

$$2\theta + \phi = 90° \Rightarrow \phi = 90° - 2\theta$$

Substituting for ϕ and AB and simplifying gives:

$$\Delta r = \frac{a}{\cos\theta} + \frac{a}{\cos\theta}\sin(90° - 2\theta)$$
$$= \frac{a}{\cos\theta} + \frac{a}{\cos\theta}\cos 2\theta$$
$$= \frac{a}{\cos\theta}(1 + \cos 2\theta)$$

Using the trigonometric identity $\cos 2\theta = 2\cos^2\theta - 1$ and simplifying yields:

$$\Delta r = \frac{a}{\cos\theta}(1 + 2\cos^2\theta - 1) = 2a\cos\theta$$

Substitute for Δr in equation (1) to obtain:

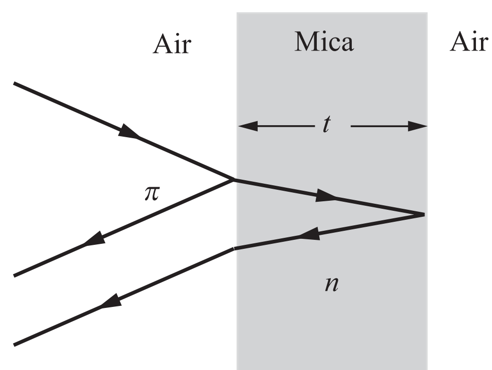
$$2a\cos\theta = m\lambda, m = 0, 1, 2, ...$$

Solving for $2a$ gives:

$$2a = \boxed{\frac{m\lambda}{\cos\theta}} \text{ where } m = 0, 1, 2, \ldots$$

84 •• A mica sheet 1.20 μm thick is suspended in air. In reflected light, there are gaps in the visible spectrum at 421, 474, 542, and 633 nm. Find the index of refraction of the mica sheet.

Picture the Problem The gaps in the spectrum of the visible light are the result of destructive interference between the incident light and the reflected light. Noting that there is a π rad phase shift at the first air-mica interface, we can use the condition for destructive interference to find the index of refraction n of the mica sheet.



Because there is a π rad phase shift at the first air-mica interface, the condition for destructive interference is:

$$2t = m\lambda_{\text{mica}} = m\frac{\lambda_{\text{air}}}{n}, m = 1, 2, 3, ...$$

Solving for n yields:

$$n = m\frac{\lambda_{\text{air}}}{2t} \qquad (1)$$

For λ = 474 nm:

$$2t = (474\,\text{nm})m$$

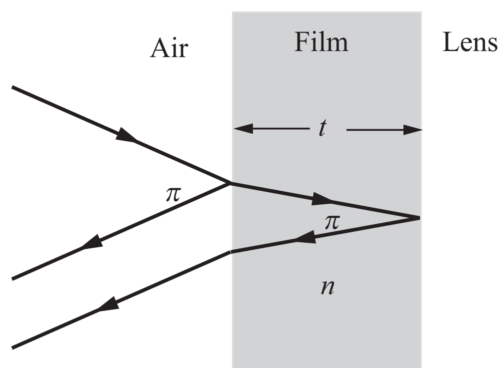
For λ = 421 nm: $$2t = (421\,\text{nm})(m+1)$$

Equate these two expressions and solve for m to obtain: $m = 8$ for λ = 474 nm

Substitute numerical values in equation (1) and evaluate n: $$n = 8\left(\frac{474\,\text{nm}}{2(1.20\,\mu\text{m})}\right) = \boxed{1.58}$$

85 •• [SSM] A camera lens is made of glass that has an index of refraction of 1.60. This lens is coated with a magnesium fluoride film (index of refraction 1.38) to enhance its light transmission. The purpose of this film is to produce zero reflection for light of wavelength 540 nm. Treat the lens surface as a flat plane and the film as a uniformly thick flat film. (*a*) What minimum thickness of this film will accomplish its objective? (*b*) Would there be destructive interference for any other visible wavelengths? (*c*) By what factor would the reflection for light of 400 nm wavelength be reduced by the presence of this film? Neglect the variation in the reflected light amplitudes from the two surfaces.

Picture the Problem Note that the light reflected at both the air-film and film-lens interfaces undergoes a π rad phase shift. We can use the condition for destructive interference between the light reflected from the air-film interface and the film-lens interface to find the thickness of the film. In (*c*) we can find the factor by which light of the given wavelengths is reduced by this film from $I \propto \cos^2 \frac{1}{2}\delta$.



(*a*) Express the condition for destructive interference between the light reflected from the air-film interface and the film-lens interface: $$2t = \left(m+\tfrac{1}{2}\right)\lambda_{\text{film}} = \left(m+\tfrac{1}{2}\right)\frac{\lambda_{\text{air}}}{n} \quad (1)$$ where $m = 0, 1, 2, \ldots$

Solving for t gives: $$t = \left(m+\tfrac{1}{2}\right)\frac{\lambda_{\text{air}}}{2n}$$

Evaluate t for $m = 0$: $$t = \left(\frac{1}{2}\right)\frac{540\,\text{nm}}{2(1.38)} = 97.83\,\text{nm} = \boxed{97.8\,\text{nm}}$$

(*b*) Solve equation (1) for λ_{air} to obtain:

$$\lambda_{\text{air}} = \frac{2tn}{m+\frac{1}{2}}$$

Evaluate λ_{air} for $m = 1$:

$$\lambda_{\text{air}} = \frac{2(97.8\,\text{nm})(1.38)}{1+\frac{1}{2}} = 180\,\text{nm}$$

No; because 180 nm is not in the visible portion of the spectrum.

(*c*) Express the reduction factor f as a function of the phase difference δ between the two reflected waves:

$$f = \cos^2 \tfrac{1}{2}\delta \qquad (2)$$

Relate the phase difference to the path difference Δr:

$$\frac{\delta}{2\pi} = \frac{\Delta r}{\lambda_{\text{film}}} \Rightarrow \delta = 2\pi\left(\frac{\Delta r}{\lambda_{\text{film}}}\right)$$

Because $\Delta r = 2t$:

$$\delta = 2\pi\left(\frac{2t}{\lambda_{\text{film}}}\right)$$

Substitute in equation (2) to obtain:

$$f = \cos^2\left[\tfrac{1}{2}2\pi\left(\frac{2t}{\lambda_{\text{film}}}\right)\right] = \cos^2\left[\frac{2\pi\, t}{\lambda_{\text{film}}}\right]$$

$$= \cos^2\left[\frac{2\pi\, nt}{\lambda_{\text{air}}}\right]$$

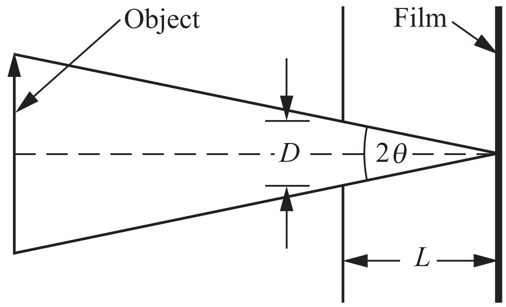
Evaluate f for $\lambda = 400$ nm:

$$f_{400} = \cos^2\left[\frac{2\pi(1.38)(97.83\,\text{nm})}{400\,\text{nm}}\right]$$

$$= \boxed{0.273}$$

86 •• In a pinhole camera, the image is fuzzy because of geometry (rays arrive at the film after passing through different parts of the pinhole) and because of diffraction. As the pinhole is made smaller, the fuzziness due to geometry is reduced, but the fuzziness due to diffraction is increased. The optimum size of the pinhole for the sharpest possible image occurs when the spread due to diffraction equals the spread due to the geometric effects of the pinhole. Estimate the optimum size of the pinhole if the distance from the pinhole to the film is 10.0 cm and the wavelength of the light is 550 nm.

Picture the Problem As indicated in the problem statement, we can find the optimal size of the pinhole by equating the angular width of the object at the film and the angular width of the diffraction pattern.



Express the angular width of the a distant object at the film in terms of the diameter D of the pinhole and the distance L from the pinhole to the object:

$$2\theta = \frac{D}{L} \Rightarrow \theta = \frac{D}{2L}$$

Using Rayleigh's criterion, express the angular width of the diffraction pattern:

$$\theta_{\text{diffraction}} = 1.22\frac{\lambda}{D}$$

Equate these two expressions to obtain:

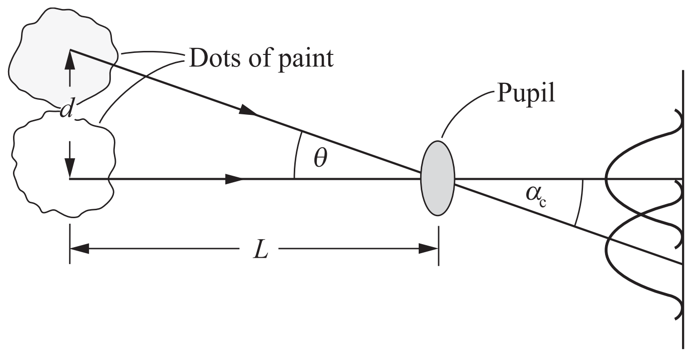
$$\frac{D}{2L} = 1.22\frac{\lambda}{D} \Rightarrow D = \sqrt{2.44\lambda L}$$

Substitute numerical values and evaluate D:

$$D = \sqrt{2.44(550\,\text{nm})(10.0\,\text{cm})} = \boxed{0.366\,\text{mm}}$$

87 •• **[SSM]** The Impressionist painter Georges Seurat used a technique called *pointillism*, in which his paintings are composed of small, closely spaced dots of pure color, each about 2.0 mm in diameter. The illusion of the colors blending together smoothly is produced in the eye of the viewer by diffraction effects. Calculate the minimum viewing distance for this effect to work properly. Use the wavelength of visible light that requires the *greatest* distance between dots, so that you are sure the effect will work for *all* visible wavelengths. Assume the pupil of the eye has a diameter of 3.0 mm.

Picture the Problem We can use the geometry of the dots and the pupil of the eye and Rayleigh's criterion to find the greatest viewing distance that ensures that the effect will work for all visible wavelengths.



Referring to the diagram, express the angle subtended by the adjacent dots:

$$\theta \approx \frac{d}{L}$$

Letting the diameter of the pupil of the eye be D, apply Rayleigh's criterion to obtain:

$$\alpha_c = 1.22\frac{\lambda}{D}$$

Set $\theta = \alpha_c$ to obtain:

$$\frac{d}{L} = 1.22\frac{\lambda}{D} \Rightarrow L = \frac{Dd}{1.22\lambda}$$

Evaluate L for the *shortest* wavelength light in the visible portion of the spectrum:

$$L = \frac{(3.0\,\text{mm})(2.0\,\text{mm})}{(1.22)(400\,\text{nm})} = \boxed{12\,\text{m}}$$

Chapter 34
Wave-Particle Duality and Quantum Physics

Conceptual Problems

1 • [SSM] The quantized character of electromagnetic radiation is observed by (*a*) the Young double-slit experiment, (*b*) diffraction of light by a small aperture, (*c*) the photoelectric effect, (*d*) the J. J. Thomson cathode-ray experiment.

Determine the Concept The Young double-slit experiment and the diffraction of light by a small aperture demonstrated the wave nature of electromagnetic radiation. J. J. Thomson's experiment showed that the rays of a cathode-ray tube were deflected by electric and magnetic fields and therefore must consist of electrically charged particles. Only the photoelectric effect requires an explanation based on the quantization of electromagnetic radiation. $\boxed{(c)}$ is correct.

2 •• Two monochromatic light sources, A and B, emit the same number of photons per second. The wavelength of A is $\lambda_A = 400$ nm, and the wavelength of B is $\lambda_B = 600$ nm. The power radiated by source B (*a*) is equal to the power of source A, (*b*) is less than the power of source A, (*c*) is greater than the power of source A, (*d*) cannot be compared to the power from source A using the available data.

Determine the Concept Since the power radiated by a source is the energy radiated per unit area and per unit time, it is directly proportional to the energy. The energy radiated varies inversely with the wavelength ($E = hc/\lambda$); i.e., the longer the wavelength, the less energy is associated with the electromagnetic radiation. $\boxed{(b)}$ is correct.

3 • [SSM] The work function of a surface is ϕ. The threshold wavelength for emission of photoelectrons from the surface is equal to (*a*) hc/ϕ, (*b*) ϕ/hf, (*c*) hf/ϕ, (*d*) none of above.

Determine the Concept The work function is equal to the minimum energy required to remove an electron from the material. A photon that has that energy also has the threshold wavelength required for photoemission. Thus, $hf = \phi$. In addition, $c = f\lambda$. It follows that $hc/\lambda_t = \phi$, so $\lambda_t = hc/\phi$ and $\boxed{(a)}$ is correct.

4 •• When light of wavelength λ_1 is incident on a certain photoelectric cathode, no electrons are emitted, no matter how intense the incident light is. Yet, when light of wavelength $\lambda_2 < \lambda_1$ is incident, electrons are emitted, even when the incident light has low intensity. Explain this observation.

Determine the Concept We can use Einstein's photoelectric equation to explain this observation.

Einstein's photoelectric equation is:

$$K_{\max} = hf - \phi$$

where ϕ, called the work function, is a characteristic of the particular metal.

Because $f = c/\lambda$:

$$K_{\max} = \frac{hc}{\lambda} - \phi$$

We're given that when light of wavelength λ_1 is incident on a certain photoelectric cathode; no electrons are emitted independently of the intensity of the incident light. Hence, we can conclude that:

$$\frac{hc}{\lambda_1} - \phi < 0 \Rightarrow \frac{hc}{\lambda_1} < \phi$$

When light of wavelength $\lambda_2 < \lambda_1$ is incident, electrons are emitted, electrons are emitted independently of the intensity of the incident light. Hence, we can conclude that:

$$\frac{hc}{\lambda_2} - \phi > 0 \Rightarrow \frac{hc}{\lambda_2} > \phi$$

Thus, photons with wavelengths greater than the threshold wavelength $\lambda_t = c/f_t$, where f_t is the threshold frequency, do not have enough energy to eject an electron from the metal.

5 • True or false:

(*a*) The wavelength of an electron's matter wave varies inversely with the momentum of the electron.
(*b*) Electrons can undergo diffraction.
(*c*) Neutrons can undergo diffraction.

(*a*) True. The de Broglie wavelength of an electron is given by $\lambda = h/p$.

(*b*) True

(*c*) True

6 • If the wavelength of an electron is equal to the wavelength of a proton, then (*a*) the speed of the proton is greater than the speed of the electron, (*b*) the speeds of the proton and the electron are equal, (*c*) the speed of the proton is less than the speed of the electron, (*d*) the energy of the proton is greater than the energy of the electron, (*e*) Both (*a*) and (*d*) are correct.

Determine the Concept If the de Broglie wavelengths of an electron and a proton are equal, their momenta must be equal. Because $m_p > m_e$, $v_p < v_e$. $\boxed{(c)}$ is correct.

7 • A proton and an electron have equal kinetic energies. It follows that the wavelength of the proton is (*a*) greater than the wavelength of the electron, (*b*) equal to the wavelength of the electron, (*c*) less than the wavelength of the electron.

Determine the Concept The kinetic energy of a particle can be expressed, in terms of its momentum, as $K = p^2/2m$. We can use the equality of the kinetic energies and the fact that $m_e < m_p$ to determine the relative sizes of their de Broglie wavelengths.

Express the equality of the kinetic energies of the proton and electron in terms of their momenta and masses:

$$\frac{p_p^2}{2m_p} = \frac{p_e^2}{2m_e}$$

Use the de Broglie relation for the wavelength of matter waves to obtain:

$$\frac{h^2}{2m_p\lambda_p^2} = \frac{h^2}{2m_e\lambda_e^2} \Rightarrow m_p\lambda_p^2 = m_e\lambda_e^2$$

Because $m_e < m_p$:

$\lambda_p^2 < \lambda_e^2$ and $\lambda_e > \lambda_p$

and $\boxed{(c)}$ is correct.

8 • The parameter x is the position of a particle, $<x>$ is the expectation value of x, and $P(x)$ is the probability density function. Can the expectation value of x ever equal a value of x for which $P(x)$ is zero? If yes, give a specific example. If no, explain why not.

Determine the Concept Yes. Consider a particle in a one-dimensional box of length L that is on the x axis on the interval $0 <x\ L$. The wave function for a particle in the n = 2 state (the lowest state above the ground state) is given by $\psi_2(x) = \sqrt{\frac{2}{L}}\sin\left(2\pi\frac{x}{L}\right)$ (see Figure 31-13). The expectation value of x is $L/2$ and $P(L/2) = 0$ (see Figure 31-14).

9 •• It was once believed that if two identical experiments are done on identical systems under the same conditions, the results must be identical. Explain how this statement can be modified so that it is consistent with quantum physics.

Determine the Concept According to quantum theory, the average value of many measurements of the same quantity will yield the expectation value of that quantity. However, any single measurement may differ from the expectation value.

10 •• A six-sided die has the numeral 1 painted on three sides and the numeral 2 painted on the other three sides. (*a*) What is the probability of a 1 coming up when the die is thrown? (*b*) What is the expectation value of the numeral that comes up when the die is thrown? (*c*) What is the expectation value of the cube of the numeral that comes up when the die is thrown?

Determine the Concept The probability of a particular event occurring is the number of ways that event can occur divided by the number of possible outcomes. The expectation value, on the other hand, is the average value of the experimental results.

(*a*) Find the probability of a 1 coming up when the die is thrown:

$$P(1) = \frac{3}{6} = \boxed{\frac{1}{2}}$$

(*b*) Find the average value of a large number of throws of the die:

$$\langle n \rangle = \frac{3\times 1 + 3\times 2}{6} = \boxed{1.5}$$

(*c*) The expectation value of the cube of the numeral that comes up when the die is thrown is:

$$\langle n \rangle = \frac{3\times 1^3 + 3\times 2^3}{6} = \boxed{4.5}$$

Estimation and Approximation

11 •• **[SSM]** During an advanced physics lab, students use X rays to measure the Compton wavelength, λ_C. The students obtain the following wavelength shifts $\lambda_2 - \lambda_1$ as a function of scattering angle θ:

θ	45°	75°	90°	135°	180°
$\lambda_2 - \lambda_1$	0.647 pm	1.67 pm	2.45 pm	3.98 pm	4.95 pm

Use their data to estimate the value for the Compton wavelength. Compare this number with the accepted value.

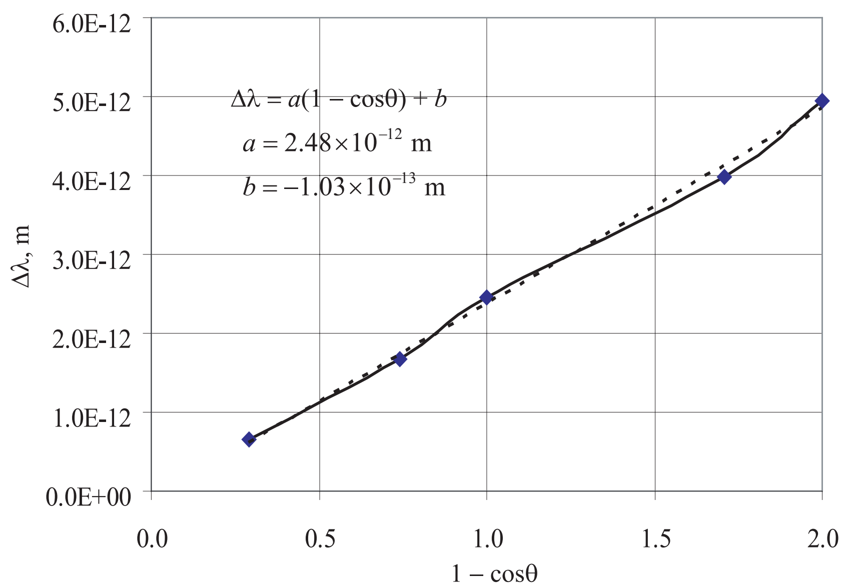
Picture the Problem From the Compton-scattering equation we have $\lambda_2 - \lambda_1 = \lambda_C(1-\cos\theta)$, where $\lambda_C = h/m_e c$ is the Compton wavelength. Note that this equation is of the form $y = mx + b$ provided we let $y = \lambda_2 - \lambda_1$ and $x = 1 - \cos\theta$. Thus, we can linearize the Compton equation by plotting $\Delta\lambda = \lambda_2 - \lambda_1$ as a function of $1-\cos\theta$. The slope of the resulting graph will yield an experimental value for the Compton wavelength.

(*a*) The spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A3	45	θ (deg)
B3	1 – cos(A3*PI()/180)	$1-\cos\theta$
C3	6.47E^–13	$\Delta\lambda = \lambda_2 - \lambda_1$

θ	$1-\cos\theta$	$\lambda_2-\lambda_1$
(deg)		
45	0.293	6.47E–13
75	0.741	1.67E–12
90	1.000	2.45E–12
135	1.707	3.98E–12
180	2.000	4.95E–12

The following graph was plotted from the data shown in the above table. Excel's ″Add Trendline″ was used to fit a linear function to the data and to determine the regression constants.



From the trend line we note that the experimental value for the Compton wavelength $\lambda_{C,exp}$ is:

$$\lambda_{C,exp} = \boxed{2.48\,\text{pm}}$$

The Compton wavelength is given by:

$$\lambda_C = \frac{h}{m_e c} = \frac{hc}{m_e c^2}$$

Substitute numerical values and evaluate λ_C:

$$\lambda_C = \frac{1240\,\text{eV}\cdot\text{nm}}{5.11\times10^5\,\text{eV}} = 2.43\,\text{pm}$$

Express the percent difference between λ_C and $\lambda_{C,exp}$:

$$\%\,\text{diff} = \frac{\lambda_{C,exp} - \lambda_{exp}}{\lambda_{exp}} = \frac{\lambda_{C,exp}}{\lambda_{exp}} - 1$$

$$= \frac{2.48\,\text{pm}}{2.43\,\text{pm}} - 1 \approx \boxed{2\%}$$

12 •• Students in a physics lab are trying to determine the value of Planck's constant *h*, using a photoelectric apparatus similar to the one shown in Figure 34-2. The students are using a helium–neon laser that has a tunable wavelength as the light source. The data that the students obtain for the maximum electron kinetic energies are

λ	544 nm	594 nm	604 nm	612 nm	633 nm
K_{max}	0.360 eV	0.199 eV	0.156 eV	0.117 eV	0.062 eV

(*a*) Using a **spreadsheet** program or graphing calculator, plot K_{max} versus light frequency. (*b*) Use the graph to estimate the value of Planck's constant. (*Note:* You may wish to use a feature of your **spreadsheet** program or graphing calculator to obtain the best straight-line fit to the data.) (*c*) Compare your result with the accepted value for Planck's constant.

Picture the Problem From Einstein's photoelectric equation we have $K_{max} = hf - \phi$, which is of the form $y = mx + b$, where the slope is *h* and the K_{max}-intercept is the work function. Hence we should plot a graph of K_{max} versus *f* in order to obtain a straight line whose slope will be an experimental value for Planck's constant.

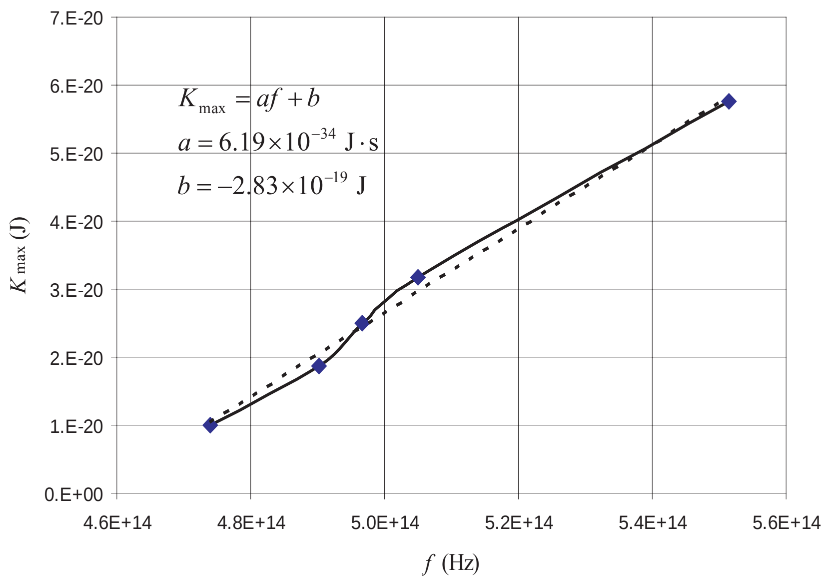
(*a*) The spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A3	544	λ (nm)
B3	0.36	K_{max} (eV)
C3	A3*10^–19	λ (m)

D3	3*10^8/C3	c/λ
E3	B3*1.6*10^−19	K_{max} (J)

λ (nm)	K_{max} (eV)	λ (m)	$f = c/\lambda$ (Hz)	K_{max} (J)
544	0.36	5.44E−07	5.51E+14	5.76E−20
594	0.199	5.94E−07	5.05E+14	3.18E−20
604	0.156	6.04E−07	4.97E+14	2.50E−20
612	0.117	6.12E−07	4.90E+14	1.87E−20
633	0.062	6.33E−07	4.74E+14	9.92E−21

The following graph was plotted from the data shown in the above table. Excel's ″Add Trendline″ was used to fit a linear function to the data and to determine the regression constants.



(b) From the trend line we note that the experimental value for Planck's constant is:

$$h_{exp} = \boxed{6.19\times10^{-34}\ \mathrm{J\cdot s}}$$

(c) Express the percent difference between h_{exp} and h:

$$\%\,\mathrm{diff} = \frac{h - h_{exp}}{h} = 1 - \frac{h_{exp}}{h}$$

$$= 1 - \frac{6.19\times10^{-34}\ \mathrm{J\cdot s}}{6.63\times10^{-34}\ \mathrm{J\cdot s}} \approx \boxed{6.6\%}$$

13 •• The cathode that was used by the students in the experiment described in Problem 12 is constructed from one of the following metals:

Metals	Tungsten	Silver	Potassium	Cesium
Work function	4.58 eV	2.4 eV	2.1 eV	1.9 eV

Determine which metal composes the cathode by using the same data given in Problem 12. (*a*) Using a **spreadsheet** program or graphing calculator, plot K_{max} versus frequency. (*b*) Use the graph to estimate the value of the work function based on the students' data. (*Note:* You may wish to use a feature of your **spreadsheet** program or graphing calculator to obtain the best straight-line fit to the data.) (*c*) Which metal was most likely used for the cathode in their experiment?

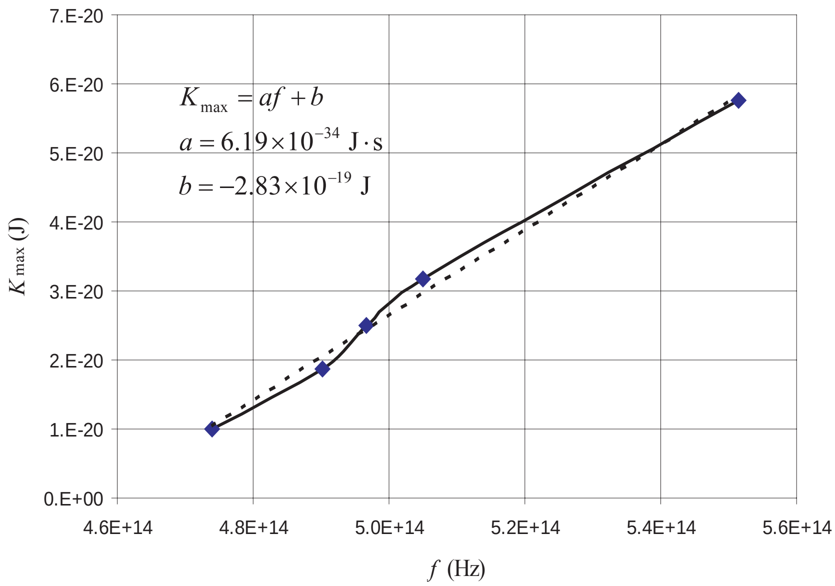
Picture the Problem From Einstein's photoelectric equation we have $K_{max} = hf - \phi$, which is of the form $y = mx + b$, where the slope is h and the K_{max}-intercept is the work function. Hence we should plot a graph of K_{max} versus f in order to obtain a straight line whose intercept will be an experimental value for the work function.

(*a*) The spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A3	544	λ (nm)
B3	0.36	K_{max} (eV)
C3	A3*10^−19	λ (m)
D3	3*10^8/C3	c/λ
E3	B3*1.6*10^−19	K_{max} (J)

λ (nm)	K_{max} (eV)	λ (m)	$f = c/\lambda$ (Hz)	K_{max} (J)
544	0.36	5.44E−07	5.51E+14	5.76E−20
594	0.199	5.94E−07	5.05E+14	3.18E−20
604	0.156	6.04E−07	4.97E+14	2.50E−20
612	0.117	6.12E−07	4.90E+14	1.87E−20
633	0.062	6.33E−07	4.74E+14	9.92E−21

The following graph was plotted from the data shown in the above table. Excel's ″Add Trendline″ was used to fit a linear function to the data and to determine the regression constants.



(*b*) From the trend line we note that the experimental value for the work function ϕ is:

$$\phi_{exp} = 2.83\times10^{-19}\ \text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}} = \boxed{1.77\,\text{eV}}$$

(*c*) The value of ϕ_{exp} = 1.77 eV is closest to the work function for $\boxed{\text{cesium}}$.

The Particle Nature of Light: Photons

14 • Find the photon energy in electron volts for light of wavelength (*a*) 450 nm, (*b*) 550 nm, and (*c*) 650 nm.

Picture the Problem We can use $E = hc/\lambda$ to find the photon energy when we are given the wavelength of the radiation.

(*a*) Express the photon energy as a function of wavelength and evaluate E for λ = 450 nm:

$$E = \frac{hc}{\lambda} = \frac{1240\,\text{eV}\cdot\text{nm}}{450\,\text{nm}} = \boxed{2.76\,\text{eV}}$$

(*b*) For λ = 550 nm:

$$E = \frac{1240\,\text{eV}\cdot\text{nm}}{550\,\text{nm}} = \boxed{2.25\,\text{eV}}$$

(*c*) For λ = 650 nm:

$$E=\frac{1240\,\text{eV}\cdot\text{nm}}{650\,\text{nm}}=\boxed{1.91\,\text{eV}}$$

15 • Find the photon energy in electron volts for an electromagnetic wave of frequency (*a*) 100 MHz in the FM radio band and (*b*) 900 kHz in the AM radio band.

Picture the Problem We can find the photon energy for an electromagnetic wave of a given frequency f from $E = hf$ where h is Planck's constant.

(*a*) For f = 100 MHz:

$$E=hf=\left(6.626\times10^{-34}\text{ J}\cdot\text{s}\right)\left(100\times10^{6}\text{ s}^{-1}\right)$$
$$=6.626\times10^{-26}\text{ J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\text{ J}}$$
$$=\boxed{4.14\times10^{-7}\text{ eV}}$$

(*b*) For f = 900 kHz:

$$E=hf=\left(6.626\times10^{-34}\text{ J}\cdot\text{s}\right)\left(900\times10^{3}\text{ s}^{-1}\right)$$
$$=5.963\times10^{-28}\text{ J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\text{ J}}$$
$$=\boxed{3.72\times10^{-9}\text{ eV}}$$

16 • What are the frequencies of photons that have the following energies (*a*) 1.00 eV, (*b*) 1.00 keV, and (*c*) 1.00 MeV?

Picture the Problem The energy of a photon, in terms of its frequency, is given by $E=hf$.

(*a*) Express the frequency of a photon in terms of its energy and evaluate f for E = 1.00 eV:

$$f=\frac{E}{h}=\frac{1.00\,\text{eV}}{4.136\times10^{-15}\text{ eV}\cdot\text{s}}$$
$$=\boxed{2.42\times10^{14}\text{ Hz}}$$

(*b*) For E = 1.00 keV:

$$f=\frac{1.00\,\text{keV}}{4.136\times10^{-15}\text{ eV}\cdot\text{s}}$$
$$=\boxed{2.42\times10^{17}\text{ Hz}}$$

(*c*) For E = 1.00 MeV:

$$f=\frac{1.00\,\text{MeV}}{4.136\times10^{-15}\text{ eV}\cdot\text{s}}$$
$$=\boxed{2.42\times10^{20}\text{ Hz}}$$

17 • Find the photon energy in electron volts if the wavelength is (*a*) 0.100 nm (about 1 atomic diameter) and (*b*) 1.00 fm (1 fm = 10^{-15} m, about 1 nuclear diameter).

Picture the Problem We can use $E = hc/\lambda$ to find the photon energy when we are given the wavelength of the radiation.

The energy of a photon as a function of its wavelength is given by:

$$E = \frac{hc}{\lambda}$$

(*a*) Substitute numerical values and evaluate E for λ = 0.100 nm:

$$E = \frac{1240\,\text{eV}\cdot\text{nm}}{0.100\,\text{nm}} = \boxed{12.4\,\text{keV}}$$

(*b*) Substitute numerical values and evaluate E for λ =1.00 fm = 1.00 × 10^{-6} nm:

$$E = \frac{1240\,\text{eV}\cdot\text{nm}}{1.00\times10^{-6}\,\text{nm}} = \boxed{1.24\,\text{GeV}}$$

18 •• The wavelength of red light emitted by a 3.00-mW helium–neon laser is 633 nm. If the diameter of the laser beam is 1.00 mm, what is the density of photons in the beam? Assume that the intensity is uniformly distributed across the beam.

Picture the Problem We can express the density of photons in the beam as the number of photons per unit volume. The number of photons per unit volume is, in turn, the ratio of the power of the laser to the energy of the photons and the volume occupied by the photons emitted in one second is the product of the cross-sectional area of the beam and the speed at which the photons travel, i.e., the speed of light.

Express the density of photons in the beam as a function of the number of photons emitted per second and the volume occupied by those photons:

$$\rho = \frac{N}{V}$$

Relate the number of photons emitted per second to the power of the laser and the energy of the photons:

$$N = \frac{P}{E} = \frac{P\lambda}{hc}$$

Express the volume containing the photons emitted in one second as a function of the cross sectional area of the beam:

$$V = Ac$$

Substitute for N and V and simplify to obtain:

$$\rho = \frac{P\lambda}{hc^2 A} = \frac{P\lambda}{hc^2\left(\frac{\pi}{4}d^2\right)} = \frac{4P\lambda}{\pi hc^2 d^2}$$

where d is the diameter of the laser beam.

Substitute numerical values and evaluate ρ:

$$\rho = \frac{4(3.00\,\text{mW})(633\,\text{nm})}{\pi(6.626\times10^{-34}\,\text{J}\cdot\text{s})(2.998\times10^{8}\,\text{m/s})^2(1.00\,\text{mm})^2} = \boxed{4.06\times10^{13}\,\text{m}^{-3}}$$

19 • **[SSM]** Lasers used in a telecommunications network typically produce light that has a wavelength near 1.55 μm. How many photons per second are being transmitted if such a laser has an output power of 2.50 mW?

Picture the Problem The number of photons per second is the ratio of the power of the laser to the energy of the photons.

Relate the number of photons emitted per second to the power of the laser and the energy of the photons:

$$N = \frac{P}{E} = \frac{P}{\frac{hc}{\lambda}} = \frac{P\lambda}{hc}$$

Substitute numerical values and evaluate N:

$$N = \frac{(2.50\,\text{mW})(1.55\,\mu\text{m})}{(6.626\times10^{-34}\,\text{J}\cdot\text{s})(2.998\times10^{8}\,\text{m/s})} = \boxed{1.95\times10^{16}\,\text{s}^{-1}}$$

The Photoelectric Effect

20 • The work function for tungsten is 4.58 eV. (*a*) Find the threshold frequency and wavelength for the photoelectric effect to occur when monochromatic electromagnetic radiation is incident on the surface of a sample of tungsten. Find the maximum kinetic energy of the electrons if the wavelength of the incident light is (*b*) 200 nm and (*c*) 250 nm.

Picture the Problem The threshold wavelength and frequency for emission of photoelectrons is related to the work function of a metal through $\phi = hf_t = hc/\lambda_t$. We can use Einstein's photoelectric equation $K_{max} = \dfrac{hc}{\lambda} - \phi$ to find the maximum kinetic energy of the electrons for the given wavelengths of the incident light.

(*a*) Express the threshold frequency in terms of the work function for tungsten and evaluate f_t:

$$f_t = \frac{\phi}{h} = \frac{4.58\,\text{eV}}{4.136\times10^{-15}\,\text{eV}\cdot\text{s}} = 1.107\times10^{15}\,\text{Hz} = \boxed{1.11\times10^{15}\,\text{Hz}}$$

Using $c = f\lambda$, express the threshold wavelength in terms of the threshold frequency and evaluate λ_t:

$$\lambda_t = \frac{c}{f_t} = \frac{2.998\times10^{8}\,\text{m/s}}{1.107\times10^{15}\,\text{Hz}} = \boxed{271\,\text{nm}}$$

(*b*) Using Einstein's photoelectric equation, relate the maximum kinetic energy of the electrons to their wavelengths and evaluate K_{max}:

$$K_{max} = E - \phi = hf - \phi = \frac{hc}{\lambda} - \phi = \frac{1240\,\text{eV}\cdot\text{nm}}{200\,\text{nm}} - 4.58\,\text{eV} = \boxed{1.62\,\text{eV}}$$

(*c*) Evaluate K_{max} for λ = 250 nm:

$$K_{max} = \frac{1240\,\text{eV}\cdot\text{nm}}{250\,\text{nm}} - 4.58\,\text{eV} = \boxed{0.380\,\text{eV}}$$

21 • When monochromatic ultraviolet light that has a wavelength equal to 300 nm is incident on a sample of potassium, the emitted electrons have maximum kinetic energy of 2.03 eV. (*a*) What is the energy of an incident photon? (*b*) What is the work function for potassium? (*c*) What would be the maximum kinetic energy of the electrons if the incident electromagnetic radiation had a wavelength of 430 nm? (*d*) What is the maximum wavelength of incident electromagnetic radiation that will result in the photoelectric emission of electrons by a sample of potassium?

Picture the Problem (*a*) We can use the Einstein equation for photon energy to find the energy of an incident photon. (*b*) and (*c*) We can use the photoelectric equation to relate the work function for potassium to the maximum energy of the photoelectrons. (*d*) The maximum wavelength of incident electromagnetic radiation that will result in the photoelectric emission of electrons can be found from $\lambda_t = hc/\phi$.

(*a*) Use the Einstein equation for photon energy to relate the energy of the incident photon to its wavelength:

$$E = \frac{hc}{\lambda} = \frac{1240\,\text{eV}\cdot\text{nm}}{300\,\text{nm}} = \boxed{4.13\,\text{eV}}$$

(*b*) Using Einstein's photoelectric equation, relate the work function for potassium to the maximum kinetic energy of the photoelectrons:

$$K_{max} = E - \phi$$

Solve for and evaluate ϕ:

$$\phi = E - K_{max} = 4.13\,\text{eV} - 2.03\,\text{eV} = \boxed{2.10\,\text{eV}}$$

(*c*) Proceeding as in (*b*) with $E = hc/\lambda$ gives:

$$K_{max} = \frac{hc}{\lambda} - \phi = \frac{1240\,\text{eV}\cdot\text{nm}}{430\,\text{nm}} - 2.10\,\text{eV} = \boxed{0.78\,\text{eV}}$$

(*d*) Express the maximum wavelength as a function of potassium's work function and evaluate λ_t:

$$\lambda_t = \frac{hc}{\phi} = \frac{1240\,\text{eV}\cdot\text{nm}}{2.10\,\text{eV}} = \boxed{590\,\text{nm}}$$

22 • The maximum wavelength of electromagnetic radiation that will result in the photoelectric emission of electrons from a sample of silver is 262 nm. (*a*) Find the work function for silver. (*b*) Find the maximum kinetic energy of the electrons if the incident radiation has a wavelength of 175 nm.

Picture the Problem (*a*) We can find the work function for silver using $\phi = hc/\lambda_t$ and (*b*) the maximum kinetic energy of the electrons using Einstein's photoelectric equation.

(*a*) Express the work function for silver as a function of the maximum wavelength of the electromagnetic radiation that will result in photoelectric emission of electrons:

$$\phi = \frac{hc}{\lambda_t}$$

Substitute numerical values and evaluate ϕ:

$$\phi = \frac{1240\,\text{eV}\cdot\text{nm}}{262\,\text{nm}} = \boxed{4.73\,\text{eV}}$$

(*b*) Using Einstein's photoelectric equation, relate the work function for silver to the maximum kinetic energy of the photoelectrons:

$$K_{\max} = E - \phi = \frac{hc}{\lambda} - \phi$$

Substitute numerical values and evaluate $K_{\max}$:

$$K_{\max} = \frac{1240\,\text{eV}\cdot\text{nm}}{175\,\text{nm}} - 4.73\,\text{eV} = \boxed{2.36\,\text{eV}}$$

23 • The work function for cesium is 1.90 eV. (*a*) Find the minimum frequency and maximum wavelength of electromagnetic radiation that will result in the photoelectric emission of electrons from a sample of cesium. Find the maximum kinetic energy of the electrons if the wavelength of the incident radiation is (*b*) 250 nm and (*c*) 350 nm.

Picture the Problem We can find the minimum frequency and maximum wavelength for cesium using $\phi = hf_{\text{t}} = hc/\lambda_{\text{t}}$ and the maximum kinetic energy of the electrons using Einstein's photoelectric equation.

(*a*) Use the Einstein equation for photon energy to express the maximum wavelength for cesium:

$$\lambda_{\text{t}} = \frac{hc}{\phi}$$

Substitute numerical values and evaluate λ_{t}:

$$\lambda_{\text{t}} = \frac{1240\,\text{eV}\cdot\text{nm}}{1.90\,\text{eV}} = \boxed{653\,\text{nm}}$$

Use $c = f\lambda$ to find the maximum frequency:

$$f_{\text{t}} = \frac{c}{\lambda_{\text{t}}} = \frac{2.998\times10^{8}\ \text{m/s}}{653\,\text{nm}} = \boxed{4.59\times10^{14}\ \text{Hz}}$$

(*b*) Using Einstein's photoelectric equation, relate the maximum kinetic energy of the photoelectrons to the wavelength of the incident light:

$$K_{\max} = \frac{hc}{\lambda} - \phi$$

Evaluating $K_{\max}$ for $\lambda = 250$ nm gives:

$$K_{\max} = \frac{1240\,\text{eV}\cdot\text{nm}}{250\,\text{nm}} - 1.90\,\text{eV} = \boxed{3.06\,\text{eV}}$$

(c) Proceed as in Part (b) with $\lambda = 350$ nm to obtain:

$$K_{max} = \frac{1240\,\text{eV}\cdot\text{nm}}{350\,\text{nm}} - 1.90\,\text{eV} = \boxed{1.64\,\text{eV}}$$

24 •• When a surface is illuminated with electromagnetic radiation of wavelength 780 nm, the maximum kinetic energy of the emitted electrons is 0.37 eV. What is the maximum kinetic energy if the surface is illuminated using radiation of wavelength 410 nm?

Picture the Problem We can use Einstein's photoelectric equation to find the work function of this surface and then apply it a second time to find the maximum kinetic energy of the photoelectrons when the surface is illuminated with light of wavelength 410 nm.

Use Einstein's photoelectric equation to relate the maximum kinetic energy of the emitted electrons to their total energy and the work function of the surface:

$$K_{max} = \frac{hc}{\lambda} - \phi \qquad (1)$$

The work function of the surface is given by:

$$\phi = E - K_{max} = \frac{hc}{\lambda} - K_{max}$$

Substitute numerical values and evaluate ϕ:

$$\phi = \frac{1240\,\text{eV}\cdot\text{nm}}{780\,\text{nm}} - 0.37\,\text{eV} = 1.22\,\text{eV}$$

Substitute for ϕ and λ in equation (1) and evaluate K_{max}:

$$K_{max} = \frac{1240\,\text{eV}\cdot\text{nm}}{410\,\text{nm}} - 1.22\,\text{eV} = \boxed{1.80\,\text{eV}}$$

Compton Scattering

25 • Find the shift in wavelength of photons scattered by free stationary electrons at $\theta = 60°$. (Assume that the electrons are initially moving with negligible speed and are virtually free of (unattached to) any atoms or molecules.)

Picture the Problem We can calculate the shift in wavelength using the Compton relationship $\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta)$.

The shift in wavelength is given by:

$$\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta)$$

Substitute numerical values and evaluate $\Delta\lambda$:

$$\Delta\lambda = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{(9.109\times10^{-31}\ \text{kg})(2.998\times10^{8}\ \text{m/s})}(1-\cos60°) = \boxed{1.2\,\text{pm}}$$

26 • When photons are scattered by electrons in a carbon sample, the shift in wavelength is 0.33 pm. Find the scattering angle. (Assume that the electrons are initially moving with negligible speed and are virtually free of (unattached to) any atoms or molecules.)

Picture the Problem We can calculate the scattering angle using the Compton relationship $\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta)$.

Using the Compton scattering equation, relate the shift in wavelength to the scattering angle:

$$\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta)$$

Solving for θ yields:

$$\theta = \cos^{-1}\left(1-\frac{m_e c}{h}\Delta\lambda\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left(1-\frac{(9.109\times10^{-31}\ \text{kg})(2.998\times10^{8}\ \text{m/s})}{6.626\times10^{-34}\ \text{J}\cdot\text{s}}(0.33\,\text{pm})\right) = \boxed{30°}$$

27 • The photons in a monochromatic beam are scattered by electrons. The wavelength of the photons that are scattered at an angle of 135° with the direction of the incident photon beam is 2.3 percent less than the wavelength of the incident photons. What is the wavelength of the incident photons?

Picture the Problem We can calculate the shift in wavelength using the Compton relationship $\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta)$.

Express the wavelength of the incident photons in terms of the fractional change in wavelength:

$$\frac{\Delta\lambda}{\lambda} = 0.023 \Rightarrow \lambda = \frac{\Delta\lambda}{0.023}$$

Using the Compton scattering equation, relate the shift in wavelength to the scattering angle:

$$\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta)$$

Substituting for $\Delta\lambda$ yields:

$$\lambda = \frac{h}{0.023 m_e c}(1-\cos\theta)$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{(0.023)(9.109\times10^{-31}\ \text{kg})(2.998\times10^{8}\ \text{m/s})}(1-\cos135°) = \boxed{0.18\,\text{nm}}$$

28 • Compton used photons of wavelength 0.0711 nm. (*a*) What is the energy of one of these photons? (*b*) What is the wavelength of the photons scattered in the direction opposite to the direction of the incident photons? (*c*) What is the energy of the photon scattered in this direction?

Picture the Problem We can use the Einstein equation for photon energy to find the energy of both the incident and scattered photon and the Compton scattering equation to find the wavelength of the scattered photon.

(*a*) Use the Einstein equation for photon energy to obtain:

$$E = \frac{hc}{\lambda_1} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.0711\,\text{nm}} = \boxed{17.4\,\text{keV}}$$

(*b*) Express the wavelength of the scattered photon in terms of its pre-scattering wavelength and the shift in its wavelength during scattering:

$$\lambda_2 = \lambda_1 + \Delta\lambda = \lambda_1 + \frac{h}{m_e c}(1-\cos\theta)$$

Substitute numerical values and evaluate λ_2:

$$\lambda_2 = 0.0711\,\text{nm} + \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{(9.109\times10^{-31}\ \text{kg})(2.998\times10^{8}\ \text{m/s})}(1-\cos180°) = \boxed{0.0760\,\text{nm}}$$

(*c*) Use the Einstein equation for photon energy to obtain:

$$E = \frac{hc}{\lambda_2} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.0760\,\text{nm}} = \boxed{16.3\,\text{keV}}$$

29 • For the photons used by Compton (see Problem 28), find the momentum of the incident photon and the momentum of the photon scattered in the direction opposite to the direction of the incident photons. Use the

conservation of momentum to find the momentum of the recoil electron in this case.

Picture the Problem Compton used X rays of wavelength 71.1 pm. Let the direction the incident photon (and the recoiling electron) is moving be the positive direction. We can use $p = h/\lambda$ to find the momentum of the incident photon and the conservation of momentum to find its momentum after colliding with the electron.

Use the expression for the momentum of a photon to find the momentum of Compton's photons:

$$p_1 = \frac{h}{\lambda_1} = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{71.1\,\text{pm}} = \boxed{9.32\times10^{-24}\ \text{kg}\cdot\text{m/s}}$$

Using the Compton scattering equation, relate the shift in wavelength to the scattering angle:

$$\lambda_2 = \lambda_1 + \lambda_C(1-\cos\theta)$$

Substitute numerical values and evaluate λ_2:

$$\lambda_2 = 71.1\,\text{pm} + \left(2.43\times10^{-12}\ \text{m}\right)(1-\cos180°) = 76.0\,\text{pm}$$

Apply conservation of momentum to obtain:

$$p_1 = p_e - p_2 \Rightarrow p_e = p_1 - p_2$$

Substitute for p_1 and p_2 and evaluate p_e:

$$p_e = 9.32\times10^{-24}\ \text{kg}\cdot\text{m/s} - \left(-\frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{76.0\,\text{pm}}\right) = \boxed{1.80\times10^{-23}\ \text{kg}\cdot\text{m/s}}$$

30 •• A beam of photons have a wavelength equal to 6.00 pm is scattered by electrons initially at rest. A photon in the beam is scattered in a direction perpendicular to the direction of the incident beam. (*a*) What is the change in wavelength of the photon? (*b*) What is the kinetic energy of the electron?

Picture the Problem We can calculate the shift in wavelength using the Compton relationship $\Delta\lambda = \frac{h}{m_e c}(1-\cos\theta) = \lambda_C(1-\cos\theta)$ and use conservation of energy to find the kinetic energy of the scattered electron.

(*a*) Use the Compton scattering equation to find the change in wavelength of the photon:

$$\Delta\lambda = \lambda_C(1-\cos\theta) = (2.43\times10^{-12}\ \mathrm{m})(1-\cos 90°) = \boxed{2.43\,\mathrm{pm}}$$

(*b*) Use conservation of energy to relate the change in the kinetic energy of the electron to the energies of the incident and scattered photon:

$$\Delta E_e = \frac{hc}{\lambda_1} - \frac{hc}{\lambda_2}$$

Find the wavelength of the scattered photon:

$$\lambda_2 = \lambda_1 + \Delta\lambda = 6.00\,\mathrm{pm} + 2.43\,\mathrm{pm} = 8.43\,\mathrm{pm}$$

Substitute numerical values and evaluate the kinetic energy of the electron (equal to the change in its energy since it was stationary prior to the collision with the photon):

$$\Delta E_e = 1240\,\mathrm{eV\cdot nm}\left(\frac{1}{6.00\,\mathrm{pm}} - \frac{1}{8.43\,\mathrm{pm}}\right) = \boxed{60\,\mathrm{keV}}$$

Electrons and Matter Waves

31 • An electron is moving at 2.5 × 10^5 m/s. Find the electron's de Broglie wavelength.

Picture the Problem We can use its definition to find the de Broglie wavelength of this electron.

Use its definition to express the de Broglie wavelength of the electron in terms of its momentum:

$$\lambda = \frac{h}{p} = \frac{h}{m_e v}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{6.626\times10^{-34}\ \mathrm{J\cdot s}}{(9.109\times10^{-31}\ \mathrm{kg})(2.5\times10^{5}\ \mathrm{m/s})} = \boxed{2.9\,\mathrm{nm}}$$

32 • An electron has a wavelength of 200 nm. Find (*a*) the magnitude of its momentum and (*b*) its kinetic energy.

Picture the Problem We can find the momentum of the electron from the de Broglie equation and its kinetic energy from $\lambda = \frac{1.226}{\sqrt{K}}\,\text{nm}$, where K is in eV.

(*a*) Use the de Broglie relation to express the momentum of the electron:

$$p = \frac{h}{\lambda} = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{200\,\text{nm}}$$
$$= \boxed{3.31\times10^{-27}\ \text{kg}\cdot\text{m/s}}$$

(*b*) Use the electron wavelength equation to relate the electron's wavelength to its kinetic energy:

$$\lambda = \frac{1.226}{\sqrt{K}}\,\text{nm}$$

Solving for K gives:

$$K = \left(\frac{1.226\,\text{eV}^{1/2}\text{nm}}{200\,\text{nm}}\right)^2$$
$$= \boxed{3.76\times10^{-5}\ \text{eV}}$$

33 •• An electron, a proton, and an alpha particle each have a kinetic energy of 150 keV. Find (*a*) the magnitudes of their momenta and (*b*) their de Broglie wavelengths.

Picture the Problem The momenta of these particles can be found from their kinetic energies. The values for the electron, however, are only approximately correct because at the given energy the speed of the electron is a significant fraction of the speed of light. The solution presented is valid only in the non-relativistic limit $v << c$. The de Broglie wavelengths of the particles are given by $\lambda = h/p$.

(*a*) The momentum of a particle p, in terms of its kinetic energy K, is given by:

$$p = \sqrt{2mK}$$

Substitute numerical values and evaluate p_e:

$$p_e = \sqrt{2m_eK} = \sqrt{2\left(9.109\times10^{-31}\ \text{kg}\right)\left(150\,\text{keV}\times\frac{1.602\times10^{-19}\ \text{C}}{\text{eV}}\right)}$$
$$= 2.092\times10^{-22}\ \text{N}\cdot\text{s} = \boxed{2.09\times10^{-22}\ \text{N}\cdot\text{s}}$$

Substitute numerical values and evaluate p_p:

$$p_p = \sqrt{2m_pK} = \sqrt{2(1.673\times10^{-27}\text{ kg})\left(150\text{ keV}\times\frac{1.602\times10^{-19}\text{ C}}{\text{eV}}\right)}$$
$$= 8.967\times10^{-21}\text{ N}\cdot\text{s} = \boxed{8.97\times10^{-21}\text{ N}\cdot\text{s}}$$

Substitute numerical values and evaluate p_α:

$$p_\alpha = \sqrt{2m_\alpha K} = \sqrt{2\left(4\text{ u}\times\frac{1.661\times10^{-27}\text{ kg}}{\text{u}}\right)\left(150\text{ keV}\times\frac{1.602\times10^{-19}\text{ C}}{\text{eV}}\right)}$$
$$= 1.787\times10^{-20}\text{ N}\cdot\text{s} = \boxed{1.79\times10^{-20}\text{ N}\cdot\text{s}}$$

(*b*) The de Broglie wavelengths of the particles are given by:

$$\lambda = \frac{h}{p} \qquad (1)$$

Substitute numerical values in equation (1) and evaluate λ_e:

$$\lambda_e = \frac{h}{p_e} = \frac{6.626\times10^{-34}\text{ J}\cdot\text{s}}{2.092\times10^{-21}\text{ N}\cdot\text{s}} = \boxed{3.17\text{ pm}}$$

Substitute numerical values in equation (1) and evaluate λ_p:

$$\lambda_p = \frac{h}{p_p} = \frac{6.626\times10^{-34}\text{ J}\cdot\text{s}}{8.967\times10^{-21}\text{ N}\cdot\text{s}} = \boxed{73.9\text{ fm}}$$

Substitute numerical values in equation (1) and evaluate λ_α:

$$\lambda_\alpha = \frac{h}{p_\alpha} = \frac{6.63\times10^{-34}\text{ J}\cdot\text{s}}{1.79\times10^{-20}\text{ N}\cdot\text{s}} = \boxed{37.0\text{ fm}}$$

34 • A neutron in a reactor has kinetic energy of approximately 0.020 eV. Calculate the wavelength of this neutron.

Picture the Problem The wavelength associated with a particle of mass *m* and kinetic energy *K* is given by $\lambda = \dfrac{1240\text{ eV}\cdot\text{nm}}{\sqrt{2mc^2K}}$.

Substituting numerical values yields:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\sqrt{2(940\,\text{MeV})(0.020\,\text{eV})}} = \boxed{0.20\,\text{nm}}$$

35 • Find the wavelength of a proton that has a kinetic energy of 2.00 MeV.

Picture the Problem The wavelength associated with a particle of mass *m* and kinetic energy *K* is given by $\lambda = \dfrac{1240\,\text{eV}\cdot\text{nm}}{\sqrt{2mc^2K}}$.

Substituting numerical values yields:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\sqrt{2(938\,\text{MeV})(2.00\,\text{MeV})}} = \boxed{20.2\,\text{fm}}$$

36 • What is the kinetic energy of a proton whose wavelength is (*a*) 1.00 nm and (*b*) 1.00 fm?

Picture the Problem We can solve Equation 34-15 ($\lambda = \dfrac{1240\,\text{eV}\cdot\text{nm}}{\sqrt{2mc^2K}}$) for the kinetic energy of the proton and use the rest energy of a proton mc^2 = 938 MeV to simplify our computation.

Solving Equation 34-15 for the kinetic energy of the proton gives:

$$K = \frac{(1240\,\text{eV}\cdot\text{nm})^2}{2mc^2\lambda^2}$$

(*a*) Substitute numerical values and evaluate *K* for λ = 1.00 nm:

$$K = \frac{(1240\,\text{eV}\cdot\text{nm})^2}{2(938\,\text{MeV})(1.00\,\text{nm})^2} = \boxed{0.820\,\text{meV}}$$

(*b*) Evaluate *K* for λ = 1.00 fm:

$$K = \frac{(1240\,\text{eV}\cdot\text{nm})^2}{2(938\,\text{MeV})(1.00\,\text{fm})^2} = \boxed{820\,\text{MeV}}$$

37 • The kinetic energy of the electrons in the electron beam in a run of Davisson and Germer's experiment was 54 eV. Calculate the wavelength of the electrons in the beam.

Picture the Problem If *K* is in electron volts, the wavelength of a particle is given by $\lambda = \dfrac{1.226}{\sqrt{K}}\,\text{nm}$ provided *K* is in eV.

Evaluate λ for $K = 54$ eV:

$$\lambda = \frac{1.226}{\sqrt{K}}\,\text{nm} = \frac{1.226}{\sqrt{54}}\,\text{nm} = \boxed{0.17\,\text{nm}}$$

38 • The distance between Li^+ and Cl^- ions in a LiCl crystal is 0.257 nm. Find the energy of electrons that have a wavelength equal to this spacing.

Picture the Problem We can use $\lambda = \frac{1.226}{\sqrt{K}}\,\text{nm}$, where K is in eV, to find the energy of electrons whose wavelength is λ.

Relate the wavelength of the electrons to their kinetic energy:

$$\lambda = \frac{1.226}{\sqrt{K}}\,\text{nm}$$

Solving for K yields:

$$K = \left(\frac{1.226\,\text{nm}\cdot\text{eV}^{1/2}}{\lambda}\right)^2$$

Substituting numerical values and evaluating K gives:

$$K = \left(\frac{1.226\,\text{nm}\cdot\text{eV}^{1/2}}{0.257\,\text{nm}}\right)^2 = \boxed{22.8\,\text{eV}}$$

39 • **[SSM]** An electron microscope uses electrons that have energies equal to 70 keV. Find the wavelength of these electrons.

Picture the Problem We can approximate the wavelength of 70-keV electrons using $\lambda = \frac{1.226}{\sqrt{K}}\,\text{nm}$, where K is in eV. This solution is, however, only approximately correct because at the given energy the speed of the electron is a significant fraction of the speed of light. The solution presented is valid only in the non-relativistic limit $v << c$.

Relate the wavelength of the electrons to their kinetic energy:

$$\lambda = \frac{1.23}{\sqrt{K}}\,\text{nm}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1.226}{\sqrt{70\times10^3\,\text{eV}}}\,\text{nm} = \boxed{4.6\,\text{pm}}$$

40 • What is the de Broglie wavelength of a neutron that has a speed of 1.00×10^6 m/s?

Picture the Problem We can use its definition to calculate the de Broglie wavelength of a neutron with speed 10^6 m/s.

Use its definition to express the de Broglie wavelength of the neutron:

$$\lambda_n = \frac{h}{p_n} = \frac{h}{m_n v_n}$$

Substitute numerical values and evaluate λ_n:

$$\lambda_n = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{\left(1.675\times10^{-27}\ \text{kg}\right)\left(1.00\times10^{6}\ \text{m/s}\right)} = \boxed{0.396\ \text{pm}}$$

A Particle in a Box

41 •• (*a*) Find the energy of the ground state ($n = 1$) and the first two excited states of a neutron in a one-dimensional box of length $L = 1.00\times10^{-15}$ m = 1.00 fm (about the diameter of an atomic nucleus). Make an energy-level diagram for this system. Calculate the wavelength of electromagnetic radiation emitted when the neutron makes a transition from (*b*) $n = 2$ to $n = 1$, (*c*) $n = 3$ to $n = 2$, and (*d*) $n = 3$ to $n = 1$.

Picture the Problem We can find the ground-state energy using $E_1 = \frac{h^2}{8mL^2}$ and the energies of the excited states using $E_n = n^2E_1$. The wavelength of the electromagnetic radiation emitted when the neutron transitions from one state to another is given by the Einstein equation for photon energy ($E = \frac{hc}{\lambda}$).

(*a*) Express the ground-state energy:

$$E_1 = \frac{h^2}{8m_n L^2}$$

Substitute numerical values and evaluate E_1:

$$E_1 = \frac{\left(6.626\times10^{-34}\ \text{J}\cdot\text{s}\right)^2}{8\left(1.6749\times10^{-27}\ \text{kg}\right)\left(1.00\times10^{-15}\ \text{m}\right)^2}\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}} = 204.53\,\text{MeV}$$
$$= \boxed{205\,\text{MeV}}$$

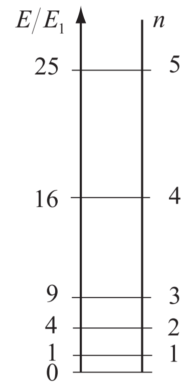
Find the energies of the first two excited states:

$$E_2 = 2^2E_1 = 4(204.53\,\text{MeV}) = \boxed{818\,\text{MeV}}$$

and

$$E_3 = 3^2E_1 = 9(204.53\,\text{MeV}) = \boxed{1.84\,\text{GeV}}$$

The energy-level diagram for this system is shown to the right:



(*b*) Relate the wavelength of the electromagnetic radiation emitted during a neutron transition to the energy released in the transition:

$$\lambda = \frac{hc}{\Delta E} = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E}$$

For the $n = 2$ to $n = 1$ transition:

$$\Delta E = E_2 - E_1 = 4E_1 - E_1 = 3E_1$$

Substitute numerical values and evaluate $\lambda_{2\to1}$:

$$\lambda_{2\to1} = \frac{1240\,\text{eV}\cdot\text{nm}}{3E_1} = \frac{1240\,\text{eV}\cdot\text{nm}}{3(204.53\,\text{MeV})} = \boxed{2.02\,\text{fm}}$$

(*c*) For the $n = 3$ to $n = 2$ transition:

$$\Delta E = E_3 - E_2 = 9E_1 - 4E_1 = 5E_1$$

Substitute numerical values and evaluate $\lambda_{3\to2}$:

$$\lambda_{3\to2} = \frac{1240\,\text{eV}\cdot\text{nm}}{5E_1} = \frac{1240\,\text{eV}\cdot\text{nm}}{5(204.53\,\text{MeV})} = \boxed{1.21\,\text{fm}}$$

(*d*) For the $n = 3$ to $n = 1$ transition:

$$\Delta E = E_3 - E_1 = 9E_1 - E_1 = 8E_1$$

Substitute numerical values and evaluate $\lambda_{3\to1}$:

$$\lambda_{3\to1} = \frac{1240\,\text{eV}\cdot\text{nm}}{8E_1} = \frac{1240\,\text{eV}\cdot\text{nm}}{8(204.53\,\text{MeV})} = \boxed{0.758\,\text{fm}}$$

42 •• (*a*) Find the energy of the ground state ($n = 1$) and the first two excited states of a neutron in a one-dimensional box of length 0.200 nm (about the diameter of a H_2 molecule). Calculate the wavelength of electromagnetic radiation emitted when the neutron makes a transition from (*b*) $n = 2$ to $n = 1$, (*c*) $n = 3$ to $n = 2$, and (*d*) $n = 3$ to $n = 1$.

Picture the Problem We can find the ground-state energy using $E_1 = \dfrac{h^2}{8mL^2}$ and the energies of the excited states using $E_n = n^2 E_1$. The wavelength of the electromagnetic radiation emitted when the neutron transitions from one state to another is given by the Einstein equation for photon energy ($E = \dfrac{hc}{\lambda}$).

(*a*) Express the ground-state energy:

$$E_1 = \frac{h^2}{8m_\mathrm{n}L^2}$$

Substitute numerical values and evaluate E_1:

$$E_1 = \frac{\left(6.626\times10^{-34}\ \mathrm{J\cdot s}\right)^2}{8\left(1.6749\times10^{-27}\ \mathrm{kg}\right)\left(0.200\,\mathrm{nm}\right)^2}\frac{1\,\mathrm{eV}}{1.602\times10^{-19}\ \mathrm{J}} = 5.1133\,\mathrm{meV} = \boxed{5.11\,\mathrm{meV}}$$

Find the energies of the first two excited states:

$$E_2 = 2^2 E_1 = 4(5.1133\,\mathrm{meV}) = \boxed{20.5\,\mathrm{meV}}$$

and

$$E_3 = 3^2 E_1 = 9(5.1133\,\mathrm{meV}) = \boxed{46.0\,\mathrm{meV}}$$

(*b*) Relate the wavelength of the electromagnetic radiation emitted during a neutron transition to the energy released in the transition:

$$\lambda = \frac{hc}{\Delta E} = \frac{1240\,\mathrm{eV\cdot nm}}{\Delta E}$$

For the $n = 2$ to $n = 1$ transition:

$$\Delta E = E_2 - E_1 = 4E_1 - E_1 = 3E_1$$

Substitute numerical values and evaluate $\lambda_{2\to1}$:

$$\lambda_{2\to1} = \frac{1240\,\mathrm{eV\cdot nm}}{3E_1} = \frac{1240\,\mathrm{eV\cdot nm}}{3(5.1133\,\mathrm{meV})} = \boxed{80.8\,\mu\mathrm{m}}$$

(*c*) For the $n = 3$ to $n = 2$ transition:

$$\Delta E = E_3 - E_2 = 9E_1 - 4E_1 = 5E_1$$

Substitute numerical values and evaluate $\lambda_{3\to2}$:

$$\lambda_{3\to2} = \frac{1240\,\mathrm{eV\cdot nm}}{5E_1} = \frac{1240\,\mathrm{eV\cdot nm}}{5(5.1133\,\mathrm{meV})} = \boxed{48.5\,\mu\mathrm{m}}$$

(*d*) For the $n = 3$ to $n = 1$ transition: $\Delta E = E_3 - E_1 = 9E_1 - E_1 = 8E_1$

Substitute numerical values and evaluate $\lambda_{3\to1}$:

$$\lambda_{3\to1} = \frac{1240\,\text{eV}\cdot\text{nm}}{8E_1} = \frac{1240\,\text{eV}\cdot\text{nm}}{8(5.1133\,\text{meV})} = \boxed{30.3\,\mu\text{m}}$$

Calculating Probabilities and Expectation Values

43 •• A particle is in the ground state of a one-dimensional box that has length L. (The box has one end at the origin and the other end on the positive x axis.) Determine the probability of finding the particle in the interval of length $\Delta x = 0.002L$ and centered at (*a*) $\frac{1}{4}x = L$, (*b*) $x = \frac{1}{2}L$, and (*c*) $x = \frac{3}{4}L$. (Because Δx is very small you need not do any integration.)

Picture the Problem The probability of finding the particle in some range Δx is $\psi^2 dx$. The interval $\Delta x = 0.002L$ is so small that we can neglect the variation in $\psi(x)$ and just compute $\psi^2\Delta x$.

Express the probability of finding the particle in the interval Δx:

$$P = P(x)\Delta x = \psi^2(x)\Delta x$$

Express the wave function for a particle in the ground state:

$$\psi_1(x) = \sqrt{\frac{2}{L}}\sin\frac{\pi x}{L}$$

Substitute for $\psi_1(x)$ to obtain:

$$P = \frac{2}{L}\sin^2\frac{\pi x}{L}\Delta x = \frac{2}{L}\left(\sin^2\frac{\pi x}{L}\right)(0.002L) = 0.004\sin^2\left(\frac{\pi x}{L}\right)$$

(*a*) Evaluate P at $x = 4L$:

$$P(4L) = 0.004\sin^2\frac{\pi(4L)}{2L} = 0.004\sin^2(2\pi) = \boxed{0}$$

(*b*) Evaluate P at $x = L/2$:

$$P(L/2) = 0.004\sin^2\frac{\pi L}{2L} = 0.004\sin^2\left(\frac{\pi}{2}\right) = \boxed{1}$$

(c) Evaluate P at $x = 3L/4$:

$$P(3L/4) = 0.004\sin^2\left(\frac{3\pi L}{4L}\right) = 0.004\sin^2\left(\frac{3\pi}{4}\right) = \boxed{0.002}$$

44 •• A particle is in the second excited state (n = 3) of a one-dimensional box that has length L. (The box has one end at the origin and the other end on the positive x axis.) Determine the probability of finding the particle in the interval of length $\Delta x = 0.002L$ and centered at (a) $x = \frac{1}{3}L$, (b) $x = \frac{1}{2}L$, and (c) $x = \frac{2}{3}L$. (Because Δx is very small you need not do any integration.)

Picture the Problem The probability of finding the particle in some range dx is $\psi^2 dx$. The interval $\Delta x = 0.002L$ is so small that we can neglect the variation in $\psi(x)$ and just compute $\psi^2\Delta x$.

Express the probability of finding the particle in the interval Δx:

$$P = P(x)\Delta x = \psi^2(x)\Delta x$$

Express the wave function for a particle in its second excited state:

$$\psi_2(x) = \sqrt{\frac{2}{L}}\sin\frac{2\pi x}{L}$$

Substitute for $\psi_2(x)$ to obtain:

$$P = \frac{2}{L}\sin^2\frac{2\pi x}{L}\Delta x = \frac{2}{L}\left(\sin^2\frac{2\pi x}{L}\right)(0.002L) = 0.004\sin^2\left(\frac{2\pi x}{L}\right)$$

(a) Evaluate P at $x = L/3$:

$$P(L/3) = 0.004\sin^2\left(\frac{2\pi L}{3L}\right) = 0.004\sin^2\left(\frac{2\pi}{3}\right) = \boxed{0.003}$$

(b) Evaluate P at $x = L/2$:

$$P(L/2) = 0.004\sin^2\left(\frac{2\pi L}{2L}\right) = 0.004\sin^2(\pi) = \boxed{0}$$

(c) Evaluate P at $x = 2L/3$:

$$P(2L/3) = 0.004\sin^2\left(\frac{4\pi L}{3L}\right) = 0.004\sin^2\left(\frac{4\pi}{3}\right) = \boxed{0.003}$$

45 •• A particle is in the first excited ($n = 2$) state of a one-dimensional box that has length L. (The box has one end at the origin and the other end on the positive x axis.) Find (a) $\langle x\rangle$ and (b) $\langle x^2\rangle$.

Picture the Problem We'll use $\langle f(x)\rangle = \int f(x)\psi^2(x)\,dx$ with $\psi_n(x) = \sqrt{\frac{2}{L}}\sin\frac{n\pi x}{L}$.

(a) Express $\psi(x)$ for the $n = 2$ state:

$$\psi_2(x) = \sqrt{\frac{2}{L}}\sin\frac{2\pi x}{L}$$

Express $\langle x\rangle$ using the $n = 2$ wave function:

$$\langle x\rangle = \int_0^L \frac{2x}{L}\sin^2\frac{2\pi x}{L}\,dx$$

Change variables by letting $\theta = \frac{2\pi x}{L}$. Then:

$$x = \frac{L}{2\pi}\theta,\ d\theta = \frac{2\pi}{L}dx,\ dx = \frac{L}{2\pi}d\theta$$

and the limits on θ are 0 and 2π.

Substitute to obtain:

$$\langle x\rangle = \frac{2}{L}\int_0^L\left(\frac{L}{2\pi}\theta\right)\sin^2\theta\left(\frac{L}{2\pi}d\theta\right) = \frac{L}{2\pi^2}\int_0^{2\pi}\theta\sin^2\theta\,d\theta$$

Use a table of integrals to evaluate the integral:

$$\langle x\rangle = \frac{L}{2\pi^2}\left[\frac{\theta^2}{4} - \frac{\theta\sin 2\theta}{4} - \frac{\cos 2\theta}{8}\right]_0^{2\pi} = \frac{L}{2\pi^2}\left[\pi^2 - \frac{1}{8} + \frac{1}{8}\right] = \boxed{\frac{L}{2}}$$

(b) Express $\langle x^2\rangle$ using the $n = 2$ wave function:

$$\langle x^2\rangle = \int_0^L \frac{2x^2}{L}\sin^2\frac{2\pi x}{L}\,dx$$

Change variables as in (*a*) and substitute to obtain:

$$\langle x^2\rangle = \frac{2}{L}\int_0^L \left(\frac{L}{2\pi}\theta\right)^2 \sin^2\theta\left(\frac{L}{2\pi}d\theta\right) = \frac{L^2}{4\pi^3}\int_0^{2\pi}\theta^2\sin^2\theta\, d\theta$$

Use a table of integrals to evaluate the integral:

$$\langle x^2\rangle = \frac{L^2}{4\pi^3}\left[\frac{\theta^3}{6} - \left(\frac{\theta^2}{4}-\frac{1}{8}\right)\sin 2\theta - \frac{\theta\cos 2\theta}{4}\right]_0^{2\pi} = \frac{L^2}{4\pi^3}\left[\frac{4\pi^3}{3}-\frac{\pi}{2}\right]$$

$$= L^2\left(\frac{1}{3}-\frac{1}{8\pi^2}\right) = \boxed{0.321L^2}$$

46 •• A particle in a one-dimensional box that has length *L* is in the first excited state ($n = 2$). (The box has one end at the origin and the other end on the positive *x* axis.) (*a*) Sketch $\psi^2(x)$ versus *x* for this state. (*b*) What is the expectation value <*x*> for this state? (*c*) What is the probability of finding the particle in some small region *dx* centered at $x = L/2$? (*d*) Are your answers for Part (*b*) and Part (*c*) contradictory? If not, explain why your answers are not contradictory.

Picture the Problem We'll use $\langle f(x)\rangle = \int f(x)\psi^2(x)dx$ with $\psi_n(x) = \sqrt{\frac{2}{L}}\sin\frac{n\pi x}{L}$. In Part (*c*) we'll use $P(x) = \psi_2^2(x)$ to determine the probability of finding the particle in some small region *dx* centered at $x = \frac{1}{2}L$.

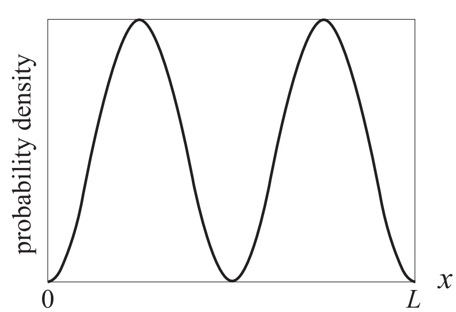
(*a*) Express the wave function for a particle in its first excited state:

$$\psi_2(x) = \sqrt{\frac{2}{L}}\sin\frac{2\pi x}{L}$$

Square both sides of the equation to obtain:

$$\psi_2^2(x) = \frac{2}{L}\sin^2\frac{2\pi x}{L}$$

The graph of $\psi^2(x)$ as a function of *x* is shown to the right:



(*b*) Express $\langle x\rangle$ using the $n = 2$ wave function:

$$\langle x\rangle = \int_0^L \frac{2x}{L}\sin^2\frac{2\pi x}{L}\,dx$$

Change variables by letting $\theta = \dfrac{2\pi x}{L}$. Then:

$$x = \frac{L}{2\pi}\theta,$$

$$d\theta = \frac{2\pi}{L}dx, \text{ and}$$

$$dx = \frac{L}{2\pi}d\theta$$

and the limits on θ are 0 and 2π.

Substitute in the expression for $\langle x\rangle$ to obtain:

$$\langle x\rangle = \frac{2}{L}\int_0^L\left(\frac{L}{2\pi}\theta\right)\sin^2\theta\left(\frac{L}{2\pi}d\theta\right)$$

$$= \frac{L}{2\pi^2}\int_0^{2\pi}\theta\sin^2\theta\,d\theta$$

Using a table of integrals, evaluate the integral:

$$\langle x\rangle = \frac{L}{2\pi^2}\left[\frac{\theta^2}{4} - \frac{\theta\sin 2\theta}{4} - \frac{\cos 2\theta}{8}\right]_0^{2\pi}$$

$$= \frac{L}{2\pi^2}\left[\pi^2 - \frac{1}{8} + \frac{1}{8}\right] = \boxed{\frac{L}{2}}$$

(*c*) Express $P(x)$:

$$P(x) = \psi_2^2(x) = \frac{2}{L}\sin^2\frac{2\pi x}{L}$$

Evaluate $P(L/2)$:

$$P\left(\frac{L}{2}\right) = \frac{2}{L}\sin^2\frac{2\pi}{L}\cdot\frac{L}{2}$$

$$= \frac{2}{L}\sin^2\pi = 0$$

Because $P(L/2) = 0$:

$$P\left(\frac{L}{2}\right)dx = \boxed{0}$$

(*d*) The answers to Parts (*b*) and (*c*) are not contradictory. Part (*b*) states that the average value of measurements of the position of the particle will yield $L/2$ even though the probability that any one measurement of position will yield this value is zero.

47 •• A particle of mass *m* has a wave function given by $\psi(x) = Ae^{-|x|/a}$, where *A* and *a* are positive constants. (*a*) Find the normalization constant *A*. (*b*) Calculate the probability of finding the particle in the region $-a \le x \le a$.

Picture the Problem We can find the constant *A* by applying the normalization condition $\int_{-\infty}^{\infty}\psi^2(x)dx = 1$ and finding the value for *A* that satisfies this condition. As soon as we have found the normalization constant, we can calculate the probability of the finding the particle in the region $-a \le x \le a$ using $P = \int_{-a}^{a}\psi^2(x)dx$.

(*a*) The normalization condition is:

$$\int_{-\infty}^{\infty}\psi^2(x)dx = 1$$

Substitute $\psi(x) = Ae^{-|x|/a}$:

$$\int_{-\infty}^{\infty}\left(Ae^{-|x|/a}\right)^2 dx = 2A^2\int_0^{\infty}e^{-2x/a}dx$$

From integral tables:

$$\int_0^{\infty}e^{-\alpha x}dx = \frac{1}{\alpha}$$

Therefore:

$$2A^2\int_0^{\infty}e^{-2x/a}dx = 2A^2\left(\frac{a}{2}\right) = aA^2 = 1$$

Solving for *A* yields:

$$A = \boxed{\frac{1}{\sqrt{a}}}$$

(*b*) Express the normalized wave function:

$$\psi(x) = \frac{1}{\sqrt{a}}e^{-|x|/a}$$

The probability of finding the particle in the region $-a \le x \le a$ is:

$$P = \int_{-a}^{a}\psi^2(x)dx = 2\int_0^{a}\frac{1}{a}e^{-2x/a}dx$$

$$= \frac{2}{a}\int_0^{a}e^{-2x/a}dx = 1 - e^{-2} = \boxed{0.865}$$

48 •• A one-dimensional box is on the *x*-axis in the region of $0 \le x \le L$. A particle in this box is in its ground state. Calculate the probability that the particle will be found in the region (*a*) $0 < x < \frac{1}{2}L$, (*b*) $0 < x < \frac{1}{3}L$, and (*c*) $0 < x < \frac{3}{4}L$.

Picture the Problem The probability density for the particle in its ground state is given by $P(x)=\frac{2}{L}\sin^2\frac{\pi}{L}x$. We'll evaluate the integral of $P(x)$ between the limits specified in (*a*), (*b*), and (*c*).

Express $P(x)$ for $0 < x < d$:

$$P(x)=\frac{2}{L}\int_0^d \sin^2\frac{\pi}{L}x\,dx$$

Change variables by letting $\theta=\frac{\pi}{L}x$. Then:

$$x=\frac{L}{\pi}\theta,\ d\theta=\frac{\pi}{L}dx,\text{ and}$$

$$dx=\frac{L}{\pi}d\theta$$

Substitute to obtain:

$$P(x)=\frac{2}{L}\int_0^{\theta'}\sin^2\theta\left(\frac{L}{\pi}d\theta\right)$$

$$=\frac{2}{\pi}\int_0^{\theta'}\sin^2\theta d\theta$$

Use a table of integrals to evaluate $\int_0^{\theta'}\sin^2\theta\,d\theta$:

$$P(x)=\frac{2}{\pi}\left[\frac{\theta}{2}-\frac{\sin 2\theta}{4}\right]_0^{\theta'} \qquad (1)$$

(*a*) Noting that the limits on θ are 0 and $\pi/2$, evaluate equation (1) over the interval $0 < x < \frac{1}{2}L$:

$$P(x)=\frac{2}{\pi}\left[\frac{\theta}{2}-\frac{\sin 2\theta}{4}\right]_0^{\pi/2}=\frac{2}{\pi}\left[\frac{\pi}{4}\right]$$

$$=\boxed{0.500}$$

(*b*) Noting that the limits on θ are 0 and $\pi/3$, evaluate equation (1) over the interval $0 < x < L/3$:

$$P(x)=\frac{2}{\pi}\left[\frac{\theta}{2}-\frac{\sin 2\theta}{4}\right]_0^{\pi/3}$$

$$=\frac{2}{\pi}\left[\frac{\pi}{6}-\frac{\sin 2\pi/3}{4}\right]$$

$$=\frac{1}{3}-\frac{\sqrt{3}}{4\pi}=\boxed{0.196}$$

(*c*) Noting that the limits on θ are 0 and $3\pi/4$, Evaluate equation (1) over the interval $0 < x < 3L/4$:

$$P(x) = \frac{2}{\pi}\left[\frac{\theta}{2} - \frac{\sin 2\theta}{4}\right]_0^{3\pi/4}$$
$$= \frac{2}{\pi}\left[\frac{3\pi}{8} - \frac{\sin 6\pi/4}{4}\right]$$
$$= \frac{3}{4} + \frac{1}{2\pi} = \boxed{0.909}$$

49 •• A one-dimensional box is on the x-axis in the region of $0 \le x \le L$. A particle in this box is in its first excited state. Calculate the probability that the particle will be found in the region (*a*) $0 < x < \frac{1}{2}L$, (*b*) $0 < x < \frac{1}{3}L$, and (*c*) $0 < x < \frac{3}{4}L$.

Picture the Problem The probability density for the particle in its first excited state is given by $P(x) = \frac{2}{L}\sin^2\frac{2\pi}{L}x$. We'll evaluate the integral of $P(x)$ between the limits specified in (*a*), (*b*), and (*c*).

Express $P(x)$ for $0 < x < d$:

$$P(x) = \frac{2}{L}\int_0^d \sin^2\frac{2\pi}{L}x\,dx$$

Change variables by letting $\theta = \frac{2\pi}{L}x$. Then:

$$x = \frac{L}{2\pi}\theta,\ d\theta = \frac{2\pi}{L}dx, \text{ and}$$
$$dx = \frac{L}{2\pi}d\theta$$

Substitute to obtain:

$$P(x) = \frac{2}{L}\int_0^{\theta'} \sin^2\theta\left(\frac{L}{2\pi}d\theta\right)$$
$$= \frac{1}{\pi}\int_0^{\theta'} \sin^2\theta\,d\theta$$

Use a table of integrals to evaluate $\int_0^{\theta'} \sin^2\theta\,d\theta$:

$$P(x) = \frac{1}{\pi}\left[\frac{\theta}{2} - \frac{\sin 2\theta}{4}\right]_0^{\theta'} \qquad (1)$$

(*a*) Noting that the limits on θ are 0 and π, evaluate equation (1) over the interval $0 < x < ½L$:

$$P(x) = \frac{1}{\pi}\left[\frac{\theta}{2} - \frac{\sin 2\theta}{4}\right]_0^{\pi} = \frac{1}{\pi}\left[\frac{\pi}{2}\right]$$
$$= \boxed{0.500}$$

(*b*) Noting that the limits on θ are 0 and $2\pi/3$, evaluate equation (1) over the interval $0 < x < L/3$:

$$P(x) = \frac{1}{\pi}\left[\frac{\theta}{2} - \frac{\sin 2\theta}{4}\right]_0^{2\pi/3} = \frac{1}{\pi}\left[\frac{2\pi}{6} - \frac{\sin 4\pi/3}{4}\right] = \frac{1}{3} + \frac{\sqrt{3}/2}{4\pi} = \boxed{0.402}$$

(*c*) Noting that the limits on θ are 0 and $3\pi/2$, evaluate equation (1) over the interval $0 < x < 3L/4$:

$$P(x) = \frac{1}{\pi}\left[\frac{\theta}{2} - \frac{\sin 2\theta}{4}\right]_0^{3\pi/2} = \frac{1}{\pi}\left[\frac{3\pi}{4}\right] = \boxed{0.750}$$

50 •• The classical probability distribution function for a particle in a one-dimensional box on the *x* axis in the region $0 < x < L$ is given by $P(x) = 1/L$. Use this expression to show that $\langle x \rangle = \frac{1}{2}L$ and $\langle x^2 \rangle = \frac{1}{3}L^2$ for a classical particle in the box.

Picture the Problem Classically, $\langle x \rangle = \int xP(x)dx$ and $\langle x^2 \rangle = \int x^2 P(x)dx$.

Evaluate $\langle x \rangle$ with $P(x) = 1/L$:

$$\langle x \rangle = \int_0^L \frac{x}{L}dx = \left[\frac{x^2}{2L}\right]_0^L = \boxed{\tfrac{1}{2}L}$$

Evaluate $\langle x^2 \rangle$ with $P(x) = 1/L$:

$$\langle x^2 \rangle = \int_0^L \frac{x^2}{L}dx = \left[\frac{x^3}{3L}\right]_0^L = \boxed{\tfrac{1}{3}L^2}$$

51 •• A one-dimensional box is on the *x*-axis in the region of $0 \le x \le L$. (*a*) The wave functions for a particle in the box are given by

$$\psi_n(x) = \sqrt{\frac{2}{L}}\sin\frac{n\pi x}{L} \qquad n = 1, 2, 3, \ldots$$

For a particle in the *n*th state, show that $\langle x \rangle = \frac{1}{2}L$ and $\langle x^2 \rangle = L^2/3 - L^2/(2n^2\pi^2)$. (*b*) Compare these expressions for $\langle x \rangle$ and $\langle x^2 \rangle$, for $n >> 1$, with the expressions for $\langle x \rangle$ and $\langle x^2 \rangle$ for the classical distribution of Problem 50.

Picture the Problem We'll use $\langle f(x) \rangle = \int f(x)\psi^2(x)dx$ with $\psi_n(x) = \sqrt{\frac{2}{L}}\sin\frac{n\pi x}{L}$ to show that $\langle x \rangle = \frac{L}{2}$ and $\langle x^2 \rangle = \frac{L^2}{3} = \frac{L^2}{2n^2\pi^2}$.

(*a*) Express $\langle x\rangle$ for a particle in the *n*th state:

$$\langle x\rangle=\int_0^L \frac{2x}{L}\sin^2\frac{n\pi x}{L}\,dx$$

Change variables by letting $\theta=\frac{n\pi x}{L}$. Then:

$$x=\frac{L}{n\pi}\theta,\ d\theta=\frac{n\pi}{L}dx,\ dx=\frac{L}{n\pi}d\theta$$

and the limits on θ are 0 and $n\pi$.

Substitute to obtain:

$$\langle x\rangle=\frac{2}{L}\int_0^{n\pi}\left(\frac{L}{n\pi}\theta\right)\sin^2\theta\left(\frac{L}{n\pi}d\theta\right)=\frac{2L}{n^2\pi^2}\int_0^{n\pi}\theta\sin^2\theta\,d\theta$$

Use a table of integrals to evaluate the integral:

$$\begin{aligned}\langle x\rangle&=\frac{2L}{n^2\pi^2}\left[\frac{\theta^2}{4}-\frac{\theta\sin 2\theta}{4}-\frac{\cos 2\theta}{8}\right]_0^{n\pi}\\&=\frac{2L}{n^2\pi^2}\left[\frac{n^2\pi^2}{4}-\frac{n\pi\sin 2n\pi}{4}-\frac{\cos 2n\pi}{8}+\frac{1}{8}\right]=\frac{2L}{n^2\pi^2}\left[\frac{n^2\pi^2}{4}-\frac{1}{8}+\frac{1}{8}\right]\\&=\boxed{\frac{L}{2}}\end{aligned}$$

Express $\langle x^2\rangle$ for a particle in the *n*th state:

$$\langle x^2\rangle=\int_0^L \frac{2x^2}{L}\sin^2\frac{n\pi x}{L}\,dx$$

Change variables by letting $\theta=\frac{n\pi x}{L}$. Then:

$$x=\frac{L}{n\pi}\theta,\ d\theta=\frac{n\pi}{L}dx,\ dx=\frac{L}{n\pi}d\theta$$

and the limits on θ are 0 and $n\pi$.

Substitute to obtain:

$$\langle x^2\rangle=\frac{2}{L}\int_0^{n\pi}\left(\frac{L}{n\pi}\theta\right)^2\sin^2\theta\left(\frac{L}{n\pi}d\theta\right)=\frac{2L^2}{n^3\pi^3}\int_0^{n\pi}\theta^2\sin^2\theta\,d\theta$$

Use a table of integrals to evaluate the integral:

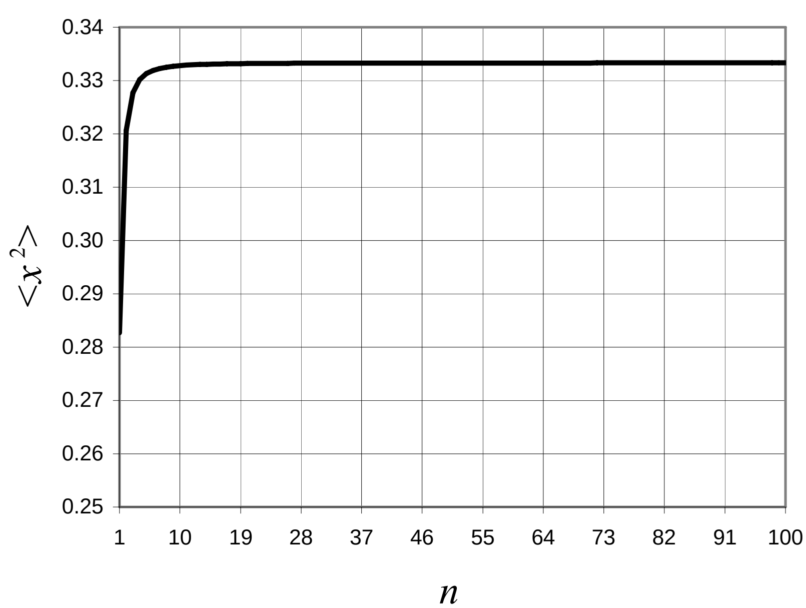
$$\langle x^2 \rangle = \frac{2L^2}{n^3\pi^3}\left[\frac{\theta^3}{6} - \left(\frac{\theta^2}{4} - \frac{1}{8}\right)\sin 2\theta - \frac{\theta\cos 2\theta}{4}\right]_0^{n\pi} = \frac{2L^2}{n^3\pi^3}\left[\frac{n^3\pi^3}{6} - \frac{n\pi}{4}\right]$$

$$= \boxed{\frac{L^2}{3} - \frac{L^2}{2n^2\pi^2}}$$

(*b*) For large values of *n* the result agrees with the classical value of $L^2/3$ given in Problem 50.

52 •• (*a*) Use a **spreadsheet** program or graphing calculator to plot $\langle x^2 \rangle$ as a function of the quantum number *n* for the particle in the box described in Problem 48 and for values of *n* from 1 to 100. Assume *L* = 1.00 m for your graph. Refer to Problem 51. (*b*) Comment on the significance of any asymptotic limits that your graph shows.

Picture the Problem (*a*) From Problem 51 we have $\langle x \rangle = \frac{L}{2}$ and $\langle x^2 \rangle = \frac{L^2}{3} - \frac{L^2}{2n^2\pi^2}$. A spreadsheet program was used to plot the following graph of $<x^2>$ as a function of *n*.



(*b*) As $n \to \infty, \langle x^2 \rangle \to \dfrac{L^2}{3}$

53 •• The wave functions for a particle of mass *m* in a one-dimensional box of length *L centered at the origin* (so that the ends are at $x = \pm\frac{1}{2}L$) are given by

$$\psi(x) = \sqrt{\frac{2}{L}}\cos\frac{n\pi x}{L} \qquad n = 1, 3, 5, 7, \ldots$$

and

$$\psi(x) = \sqrt{\frac{2}{L}}\sin\frac{n\pi x}{L} \qquad n = 2, 4, 6, 8, \ldots$$

Calculate $\langle x \rangle$ and $\langle x^2 \rangle$ for the ground state ($n = 1$).

Picture the Problem For the ground state, $n = 1$ and so we'll evaluate $\langle f(x) \rangle = \int f(x)\psi^2(x)dx$ using $\psi_1(x) = \sqrt{\dfrac{2}{L}}\cos\dfrac{\pi x}{L}$.

Because $\psi_1^2(x)$ is an even function of x, $x\psi_1^2(x)$ is an odd function of x. It follows that the integral of $x\psi_1^2(x)$ between $-L/2$ and $L/2$ is zero. Thus:

$$\langle x \rangle = \boxed{0} \text{ for all values of } n.$$

Express $\langle x^2 \rangle$:

$$\langle x^2 \rangle = \frac{2}{L}\int_{-L/2}^{L/2} x^2\cos^2\frac{\pi}{L}x\,dx$$

Change variables by letting $\theta = \dfrac{\pi x}{L}$. Then:

$$x = \frac{L}{\pi}\theta,\ d\theta = \frac{\pi}{L}dx,\ dx = \frac{L}{\pi}d\theta$$

and the limits on θ are $-\pi/2$ and $\pi/2$.

Substitute for x and dx to obtain:

$$\langle x^2 \rangle = \frac{2}{L}\int_{-\pi/2}^{\pi/2}\left(\frac{L}{\pi}\theta\right)^2\cos^2\theta\left(\frac{L}{\pi}d\theta\right)$$

$$= \frac{2L^2}{\pi^3}\int_{-\pi/2}^{\pi/2}\theta^2\cos^2\theta\,d\theta$$

Use a trigonometric identity to rewrite the integrand:

$$\langle x^2 \rangle = \frac{2L^2}{\pi^3}\int_{-\pi/2}^{\pi/2}\theta^2\left(1-\sin^2\theta\right)d\theta$$

$$= \frac{2L^2}{\pi^3}\left[\int_{-\pi/2}^{\pi/2}\theta^2 d\theta - \int_{-\pi/2}^{\pi/2}\theta^2\sin^2\theta\,d\theta\right]$$

Evaluate the second integral by looking it up in the tables:

$$\langle x^2\rangle = \frac{2L^2}{\pi^3}\left[\frac{\theta^3}{3} - \left\{\frac{\theta^3}{6} - \left(\frac{\theta^2}{4} - \frac{1}{8}\right)\sin 2\theta - \frac{\theta\cos 2\theta}{4}\right\}\right]_{-\pi/2}^{\pi/2}$$

$$= \frac{2L^2}{\pi^3}\left[\frac{\theta^3}{6} + \left(\frac{\theta^2}{4} - \frac{1}{8}\right)\sin 2\theta + \frac{\theta\cos 2\theta}{4}\right]_{-\pi/2}^{\pi/2}$$

$$= \frac{2L^2}{\pi^3}\left[\frac{\pi^3}{48} + \left(\frac{\pi^2}{16} - \frac{1}{8}\right)\sin\pi + \frac{\pi\cos\pi}{8}\right.$$

$$\left.+\frac{\pi^3}{48} + \left(\frac{\pi^2}{16} - \frac{1}{8}\right)\sin\pi + \frac{\pi\cos\pi}{8}\right]$$

$$= \frac{2L^2}{\pi^3}\left[\frac{\pi^3}{24} - \frac{\pi}{4}\right] = \boxed{L^2\left[\frac{1}{12} - \frac{1}{2\pi^2}\right]}$$

Remarks: The result differs from that of Example 34-8. Since we have shifted the origin by $\Delta x = L/2$, we could have arrived at the above result, without performing the integration, by subtracting $(\Delta x)^2 = L^2/4$ from $\langle x^2\rangle$.

54 •• Calculate $<x>$ and $<x^2>$ for the first excited state ($n = 2$) of the box described in Problem 53.

Picture the Problem For the first excited state, $n = 2$, and so we'll evaluate $\langle f(x)\rangle = \int f(x)\psi^2(x)dx$ using $\psi_2(x) = \sqrt{\frac{2}{L}}\sin\frac{2\pi x}{L}$.

Because $\psi_2^2(x)$ is an even function of x, $x\psi_2^2(x)$ is an odd function of x. It follows that the integral of $x\psi_2^2(x)$ between $-L/2$ and $L/2$ is zero. Thus:

$$\langle x\rangle = \boxed{0}$$

Express $\langle x^2\rangle$:

$$\langle x^2\rangle = \frac{2}{L}\int_{-L/2}^{L/2} x^2\sin^2\frac{2\pi}{L}x\,dx$$

Change variables by letting $\theta = \frac{2\pi x}{L}$. Then:

$x = \frac{L}{2\pi}\theta, d\theta = \frac{2\pi}{L}dx, dx = \frac{L}{2\pi}d\theta$ and the limits on θ are $-\pi$ and π.

Substitute to obtain:

$$\langle x^2 \rangle = \frac{2}{L}\int_{-\pi}^{\pi}\left(\frac{L}{2\pi}\theta\right)^2 \sin^2\theta\left(\frac{L}{2\pi}d\theta\right)$$
$$= \frac{L^2}{4\pi^3}\int_{-\pi}^{\pi}\theta^2\sin^2\theta\,d\theta$$

Evaluate the integral by looking it up in the tables:

$$\langle x^2 \rangle = \frac{L^2}{4\pi^3}\left[\frac{\theta^3}{6} - \left(\frac{\theta^2}{4} - \frac{1}{8}\right)\sin 2\theta - \frac{\theta\cos 2\theta}{4}\right]_{-\pi}^{\pi}$$
$$= \frac{L^2}{4\pi^3}\left[\frac{\pi^3}{6} - \left(\frac{\pi^2}{4} - \frac{1}{8}\right)\sin 2\pi - \frac{\pi\cos 2\pi}{4}\right.$$
$$\left. + \frac{\pi^3}{6} - \left(\frac{\pi^2}{4} - \frac{1}{8}\right)\sin 2\pi - \frac{\pi\cos 2\pi}{4}\right]$$
$$= \frac{L^2}{4\pi^3}\left[\frac{\pi^3}{6} - \frac{\pi}{4} + \frac{\pi^3}{6} - \frac{\pi}{4}\right]$$
$$= \frac{L^2}{4\pi^3}\left[\frac{\pi^3}{3} - \frac{\pi}{2}\right] = \boxed{L^2\left[\frac{1}{12} - \frac{1}{8\pi^2}\right]}$$

Remarks: The result differs from that of Example 34-8. Since we have shifted the origin by $\Delta x = L/2$, we could have arrived at the above result, without performing the integration, by subtracting $(\Delta x)^2 = L^2/4$ from $\langle x^2 \rangle$.

General Problems

55 • [SSM] Photons in a uniform 4.00-cm-diameter light beam have wavelengths equal to 400 nm and the beam has an intensity of 100 W/m^2.
(*a*) What is the energy of each photon in the beam? (*b*) How much energy strikes an area of 1.00 cm^2 perpendicular to the beam in 1 s? (*c*) How many photons strike this area in 1.00 s?

Picture the Problem We can use the Einstein equation for photon energy to find the energy of each photon in the beam. The intensity of the energy incident on the surface is the ratio of the power delivered by the beam to its delivery time. Hence, we can express the energy incident on the surface in terms of the intensity of the beam.

(a) Use the Einstein equation for photon energy to express the energy of each photon in the beam:

$$E_{\text{photon}} = hf = \frac{hc}{\lambda}$$

Substitute numerical values and evaluate E_{photon}:

$$E_{\text{photon}} = \frac{1240\,\text{eV}\cdot\text{nm}}{400\,\text{nm}} = 3.100\,\text{eV}$$
$$= \boxed{3.10\,\text{eV}}$$

(b) Relate the energy incident on a surface of area A to the intensity of the beam:

$$E = IA\Delta t$$

Substitute numerical values and evaluate E:

$$E = \left(100\,\text{W/m}^2\right)\left(1.00\times10^{-4}\,\text{m}^2\right)\left(1.00\,\text{s}\right)$$
$$= 0.0100\,\text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}$$
$$= 6.242\times10^{16}\,\text{eV} = \boxed{6.24\times10^{16}\,\text{eV}}$$

(c) Express the number of photons striking this area in 1.00 s as the ratio of the total energy incident on the surface to the energy delivered by each photon:

$$N = \frac{E}{E_{\text{photon}}} = \frac{6.242\times10^{16}\,\text{eV}}{3.100\,\text{eV}}$$
$$= \boxed{2.08\times10^{16}}$$

56 • A 1-μg particle is moving with a speed of approximately 1 mm/s in a one-dimensional box that has a length equal to 1 cm. Calculate the approximate value of the quantum number n of the state occupied by the particle.

Picture the Problem The particle's nth-state energy is $E_n = n^2\dfrac{h^2}{8mL^2}$. We can find n by solving this equation for n and substituting the particle's kinetic energy for E_n.

Express the energy of the particle when it is in its nth state:

$$E_n = n^2\frac{h^2}{8mL^2} \Rightarrow n = \frac{L}{h}\sqrt{8mE_n}$$

Express the energy (kinetic) of the particle:

$$E_n = \tfrac{1}{2}mv^2$$

Substitute for E_n and simplify to obtain:

$$n = \frac{2mvL}{h}$$

Substitute numerical values and evaluate n:

$$n = \frac{2(10^{-9}\text{ kg})(1\times10^{-3}\text{ m/s})(10^{-2}\text{ m})}{6.626\times10^{-34}\text{ J}\cdot\text{s}} \approx \boxed{3\times10^{19}}$$

57 • (*a*) For the particle and box of Problem 56, find Δx and Δp_x, assuming that these uncertainties are given by $\Delta x/L = 0.01$ percent and $\Delta p_x/p_x = 0.01$ percent. (*b*) What is $(\Delta x \Delta p_x)/h$?

Picture the Problem We can use the fact that the uncertainties are given by $\Delta x/L = 0.01$ percent and $\Delta p_x/p_x = 0.01$ percent to find Δx and Δp.

(*a*) Assuming that $\Delta x/L = 0.01$ percent, find Δx:

$$\Delta x = 10^{-4}(L) = 10^{-4}(10^{-2}\text{ m}) = \boxed{1\,\mu\text{m}}$$

Assuming that $\Delta p_x/p_x = 0.01$ percent, find Δp:

$$\Delta p_x = 10^{-4}mv = 10^{-4}(10^{-9}\text{ kg})(10^{-3}\text{ m/s}) = \boxed{10^{-16}\text{ kg}\cdot\text{m/s}}$$

(*b*) Evaluate $(\Delta x \Delta p_x)/h$:

$$\frac{\Delta x \Delta p_x}{h} = \frac{(1\,\mu\text{m})(10^{-16}\text{ kg}\cdot\text{m/s})}{6.626\times10^{-34}\text{ J}\cdot\text{s}} = \boxed{2\times10^{11}}$$

58 • In 1987, a laser at Los Alamos National Laboratory produced a flash that lasted 1×10^{-12} s and had a power of 5×10^{15} W. Estimate the number of emitted photons, assuming they all had wavelengths equal to 400 nm.

Picture the Problem We can estimate the number of emitted photons from the ratio of the total energy in the flash to the energy of a single photon.

Letting N be the number of emitted photons, express the ratio of the total energy in the flash to the energy of a single photon:

$$N = \frac{E}{E_{\text{photon}}}$$

Relate the energy in the flash to the power produced:

$$E = P\Delta t$$

Express the energy of a single photon as a function of its wavelength:

$$E_{\text{photon}} = \frac{hc}{\lambda}$$

Substituting for E and E_{photon} and simplifying gives:

$$N = \frac{P\Delta t\lambda}{hc}$$

Substitute numerical values and evaluate N:

$$N = \frac{(5\times10^{15}\ \text{W})(1\times10^{-12}\ \text{s})(400\times10^{-9}\ \text{m})}{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})} \approx \boxed{1\times10^{22}}$$

59 • You cannot "see" anything smaller than the wavelength of the wave used to make the observation. What is the minimum energy of an electron needed in an electron microscope to "see" an atom that has a diameter of about 0.1 nm?

Picture the Problem We can use the electron wavelength equation $\lambda = \frac{1.23}{\sqrt{K}}\text{nm}$, where K is in eV to find the minimum energy required to see an atom.

Relate the energy of the electron to the size of an atom (the wavelength of the electron):

$$\lambda = \frac{1.23}{\sqrt{K}}\text{nm} \Rightarrow K = \frac{(1.23\,\text{eV}^{1/2}\cdot\text{nm})^2}{\lambda^2}$$

provided K is in eV.

Substitute numerical values and evaluate K:

$$K = \frac{(1.23\,\text{eV}^{1/2}\cdot\text{nm})^2}{(0.1\,\text{nm})^2} \approx \boxed{0.2\,\text{keV}}$$

60 • A common flea that has a mass of 0.008 g can jump vertically as high as 20 cm. Estimate the de Broglie wavelength for the flea immediately after takeoff.

Picture the Problem The flea's de Broglie wavelength is $\lambda = h/p$, where p is the flea's momentum immediately after takeoff. We can use a constant acceleration equation to find the flea's speed and, hence, momentum immediately after takeoff.

Express the de Broglie wavelength of the flea immediately after takeoff:

$$\lambda = \frac{h}{p} = \frac{h}{mv_0}$$

Using a constant acceleration equation, express the height the flea can jump as a function of its takeoff speed:

$$v^2 = v_0^2 + 2a\Delta y$$

or, since $v = 0$ and $a = -g$,

$$v_0 = \sqrt{2g\Delta y}$$

Substitute to obtain:

$$\lambda = \frac{h}{m\sqrt{2g\Delta y}}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{\left(8\times10^{-6}\ \text{kg}\right)\sqrt{2\left(9.81\,\text{m/s}^2\right)\left(0.2\,\text{m}\right)}} \approx \boxed{4\times10^{-29}\ \text{m}}$$

61 •• [SSM] A 100-W source radiates light of wavelength 600 nm uniformly in all directions. An eye that has been adapted to the dark has a 7-mm-diameter pupil and can detect the light if at least 20 photons per second enter the pupil. How far from the source can the light be detected under these rather extreme conditions?

Picture the Problem We can relate the fraction of the photons entering the eye to ratio of the area of the pupil to the area of a sphere of radius R. We can find the number of photons emitted by the source from the rate at which it emits and the energy of each photon which we can find using the Einstein equation.

Letting r be the radius of the pupil, $N_{\text{entering eye}}$ the number of photons per second entering the eye, and N_{emitted} the number of photons emitted by the source per second, express the fraction of the light energy entering the eye at a distance R from the source:

$$\frac{N_{\text{entering eye}}}{N_{\text{emitted}}} = \frac{A_{\text{eye}}}{4\pi R^2} = \frac{\pi r^2}{4\pi R^2} = \frac{r^2}{4R^2}$$

Solving for R yields:

$$R = \frac{r}{2}\sqrt{\frac{N_{\text{emitted}}}{N_{\text{entering eye}}}} \qquad (1)$$

Find the number of photons emitted by the source per second:

$$N_{\text{emitted}} = \frac{P}{E_{\text{photon}}}$$

Using the Einstein equation, express the energy of the photons:

$$E_{\text{photon}} = \frac{hc}{\lambda}$$

Substitute numerical values and evaluate E_{photon}:

$$E_{\text{photon}} = \frac{1240\,\text{eV}\cdot\text{nm}}{600\,\text{nm}} = 2.07\,\text{eV}$$

Substitute and evaluate N_{emitted}:

$$N_{\text{emitted}} = \frac{100\,\text{W}}{(2.07\,\text{eV})\left(1.602\times10^{-19}\,\frac{\text{J}}{\text{eV}}\right)} = 3.02\times10^{20}\,\text{s}^{-1}$$

Substitute for N_{emitted} in equation (1) and evaluate R:

$$R = \frac{3.5\,\text{mm}}{2}\sqrt{\frac{3.02\times10^{20}\,\text{s}^{-1}}{20\,\text{s}^{-1}}} \approx \boxed{7\times10^{3}\,\text{km}}$$

62 •• The diameter of the pupil of an eye under room-light conditions is approximately 5 mm. Find the intensity of light that has a wavelength equal to 600 nm so that 1 photon per second passes through the pupil.

Picture the Problem The intensity of the light such that one photon per second passes through the pupil is the ratio of the energy of one photon to the product of the area of the pupil and time interval during which the photon passes through the pupil. We'll use the Einstein equation to express the energy of the photon.

Use its definition to relate the intensity of the light to the energy of a 600-nm photon:

$$I_{1\,\text{photon}} = \frac{P}{A} = \frac{E_{1\,\text{photon}}}{A\Delta t}$$

Using the Einstein equation, express the energy of a 600-nm photon:

$$E_{1\,\text{photon}} = \frac{hc}{\lambda}$$

Substitute for $E_{1\,\text{photon}}$ to obtain:

$$I_{1\,\text{photon}} = \frac{hc}{\lambda A\Delta t}$$

Substitute numerical values and evaluate $I_{1\,\text{photon}}$:

$$I_{1\,\text{photon}} = \frac{(1240\,\text{eV}\cdot\text{nm})(1.602\times10^{-19}\,\text{J/eV})}{(600\,\text{nm})\left[\frac{\pi}{4}(5\times10^{-3}\,\text{m})^2\right](1\,\text{s})} \approx \boxed{2\times10^{-14}\,\text{W/m}^2}$$

63 •• A 100-W incandescent light bulb radiates 2.6 W of visible light uniformly in all directions. (*a*) Find the intensity of the light from the bulb at a distance of 1.5 m. (*b*) If the average wavelength of the visible light is 650 nm, and counting only those photons in the visible spectrum, find the number of photons per second that strike a surface that has an area equal to 1.0 cm^2, is oriented so that the line to the bulb is perpendicular to the surface, and is a distance of 1.5 m from the bulb.

Picture the Problem We can find the intensity at a distance of 1.5 m directly from its definition. The number of photons striking the surface each second can be found from the ratio of the energy incident on the surface to the energy of a 650-nm photon.

(*a*) Use its definition to express the intensity of the light as a function of distance from the light bulb:

$$I = \frac{P}{A} = \frac{P}{4\pi R^2}$$

Substitute numerical data to obtain:

$$I = \frac{2.6\,\text{W}}{4\pi(1.5\,\text{m})^2} = 91.96\,\text{mW/m}^2$$
$$= \boxed{92\,\text{mW/m}^2}$$

(*b*) Express the number of photons per second that strike the surface as the ratio of the energy incident on the surface to the energy of a 650-nm photon:

$$N = \frac{IA}{E_{\text{photon}}}$$

where A is the area of the surface.

Use the Einstein equation to express the energy of the 650-nm photons:

$$E = \frac{hc}{\lambda}$$

Substituting for E yields:

$$N = \frac{IA\lambda}{hc}$$

Substitute numerical values and evaluate N:

$$N = \frac{(91.96\,\text{mW/m}^2)(1.0\times10^{-4}\,\text{m}^2)(650\,\text{nm})}{(1240\,\text{eV}\cdot\text{nm})\left(1.602\times10^{-19}\,\frac{\text{J}}{\text{eV}}\right)} = \boxed{3.0\times10^4}$$

64 •• When light of wavelength λ_1 is incident on the cathode of a photoelectric tube, the maximum kinetic energy of the emitted electrons is 1.8 eV. If the wavelength is reduced to $\frac{1}{2}\lambda_1$, the maximum kinetic energy of the emitted electrons is 5.5 eV. Find the work function ϕ of the cathode material.

Picture the Problem The maximum kinetic energy of the photoelectrons is related to the frequency of the incident photons and the work function of the cathode material through the Einstein equation. We can apply this equation to the two sets of data and solve the resulting equations simultaneously for the work function.

Using the Einstein equation, relate the maximum kinetic energy of the emitted electrons to the frequency of the incident photons and the work function of the cathode material:

$$K_{\text{max}} = hf - \phi = \frac{hc}{\lambda} - \phi$$

Substitute numerical values for the light of wavelength λ_1:

$$1.8\,\text{eV} = \frac{hc}{\lambda_1} - \phi \qquad (1)$$

Substitute numerical values for the light of wavelength $\frac{1}{2}\lambda_1$:

$$5.5\,\text{eV} = \frac{hc}{\frac{1}{2}\lambda_1} - \phi = \frac{2hc}{\lambda_1} - \phi \qquad (2)$$

Solve equations (1) and (2) simultaneously for ϕ to obtain:

$$\phi = \boxed{1.9\,\text{eV}}$$

65 •• An incident photon of energy E_i undergoes Compton scattering at an angle of θ. Show that the energy E_s of the scattered photon is given by

$$E_s = \frac{E_i}{1 + \left(E_i/m_e c^2\right)(1 - \cos\theta)}$$

Picture the Problem We can use the Einstein equation to express the energy of the scattered photon in terms of its wavelength and the Compton scattering equation to relate this wavelength to the scattering angle and the pre-scattering wavelength.

Express the energy of the scattered photon E_s as a function of their wavelength λ_s:

$$E_s = \frac{hc}{\lambda_s}$$

Express the wavelength of the scattered photon as a function of the scattering angle θ:

$$\lambda_s = \frac{h}{m_e c}(1 - \cos\theta) + \lambda$$

where λ is the wavelength of the incident photon.

Substitute for λ and simplify to obtain:

$$E_s = \frac{hc}{\frac{h}{m_e c}(1-\cos\theta)+\lambda}$$

$$= \frac{\frac{hc}{\lambda}}{1+\frac{hc}{m_e c^2 \lambda}(1-\cos\theta)}$$

$$= \boxed{\frac{E_i}{1+\left(\frac{E_i}{m_e c^2}\right)(1-\cos\theta)}}$$

66 •• A particle is confined to a one-dimensional box. While the particle makes a transition from the state n to the state $n-1$, radiation of 114.8 nm is emitted. While the particle makes the transition from the state $n-1$ to the state $n-2$, radiation of wavelength 147 nm is emitted. The ground-state energy of the particle is 1.2 eV. Determine n.

Picture the Problem While we can work with either of the transitions described in the problem statement, we'll use the first transition in which radiation of wavelength 114.8 nm is emitted. We can express the energy released in the transition in terms of the difference between the energies in the two states and solve the resulting equation for n.

Express the energy of the emitted radiation as the particle goes from the nth to $n-1$ state:

$$\Delta E = E_n - E_{n-1}$$

Express the energy of the particle in nth state:

$$E_n = n^2 E_1$$

Express the energy of the particle in the $n-1$ state:

$$E_{n-1} = (n-1)^2 E_1$$

Substitute for E_n and E_{n-1} and simplify to obtain:

$$\Delta E = n^2 E_1 - (n-1)^2 E_1$$

$$= (2n-1)E_1 = \frac{hc}{\lambda}$$

Solving for n yields:

$$n = \frac{hc}{2\lambda E_1} + \frac{1}{2}$$

Substitute numerical values and evaluate n:

$$n = \frac{1240\,\text{eV}\cdot\text{nm}}{2(114.8\,\text{nm})(1.2\,\text{eV})} + \frac{1}{2} = \boxed{5}$$

67 •• [SSM] The Pauli exclusion principle states that no more than one electron may occupy a particular quantum state at a time. Electrons intrinsically occupy two spin states. Therefore, if we wish to model an atom as a collection of electrons trapped in a one-dimensional box, no more than two electrons in the box can have the same value of the quantum number n. Calculate the energy that the most energetic electron(s) would have for the uranium atom that has an atomic number 92. Assume the box has a length of 0.050 nm and the electrons are in the lowest possible energy states. How does this energy compare to the rest energy of the electron?

Picture the Problem We can use the expression for the energy of a particle in a well to find the energy of the most energetic electron in the uranium atom.

Relate the energy of an electron in the uranium atom to its quantum number n:

$$E_n = n^2\left(\frac{h^2}{8m_e L^2}\right)$$

Substitute numerical values and evaluate E_{92}:

$$E_{92} = (92)^2\left[\frac{(6.626\times10^{-34}\,\text{J}\cdot\text{s})^2}{8(9.109\times10^{-31}\,\text{kg})(0.050\,\text{nm})^2} \times \frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\right] = 1.273\,\text{MeV}$$
$$= \boxed{1.3\,\text{MeV}}$$

The rest energy of an electron is:

$$m_e c^2 = (9.109\times10^{-31}\,\text{kg})(2.998\times10^8\,\text{m/s})^2\left(\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\right) = 0.512\,\text{MeV}$$

Express the ratio of E_{92} to $m_e c^2$:

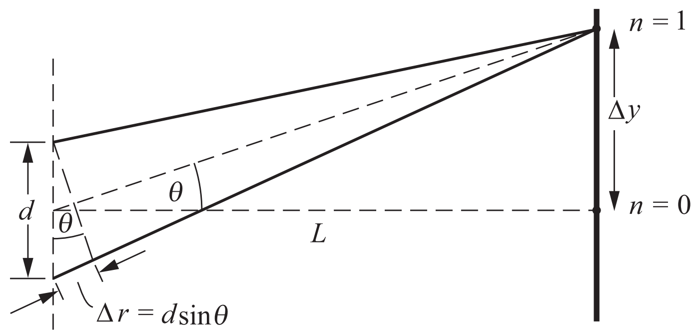
$$\frac{E_{92}}{m_e c^2} = \frac{1.273\,\text{MeV}}{0.512\,\text{MeV}} \approx 2.5$$

The energy of the most energetic electron is approximately 2.5 times the rest-energy of an electron.

68 •• A beam of electrons that each have the same kinetic energy illuminates a pair of slits separated by a distance 54 nm. The beam forms bright and dark fringes on a screen located a distance 1.5 m beyond the two slits. The arrangement is otherwise identical to that used in the optical two-slit interference

experiment described in Chapter 33 and in Figure 33-7 and the fringes have the appearance shown in Figure 34-18*d*. The bright fringes are found to be separated by a distance of 0.68 mm. What is the kinetic energy of the electrons in the beam?

Picture the Problem We can express the kinetic energy of an electron in the beam in terms of its momentum. We can use the de Broglie relationship to relate the electron's momentum to its wavelength and use the condition for constructive interference to find λ.



Express the kinetic energy of an electron in terms of its momentum:

$$K = \frac{p^2}{2m} \quad (1)$$

Using the de Broglie relationship, relate the momentum of an electron to its wavelength:

$$p = \frac{h}{\lambda}$$

Substitute for p in equation (1) to obtain:

$$K = \frac{h^2}{2m\lambda^2} \quad (2)$$

The condition for constructive interference is:

$$d\sin\theta = n\lambda \Rightarrow \lambda = \frac{d\sin\theta}{n}$$

where d is the slit separation and $n = 0, 1, 2, \ldots$

For $\theta << 1$, $\sin\theta$ is also given by:

$$\sin\theta \approx \frac{\Delta y}{L}$$

Substitute for $\sin\theta$ to obtain:

$$\lambda = \frac{d\Delta y}{nL}$$

Substitute for λ in equation (2) to obtain:

$$K = \frac{n^2L^2h^2}{2md^2(\Delta y)^2}$$

Substitute numerical values (n = 1) and evaluate K:

$$K = \frac{(1)^2(1.5\,\text{m})^2\left(6.626\times10^{-34}\,\text{J}\cdot\text{s}\right)^2}{2\left(9.109\times10^{-31}\,\text{kg}\right)(54\,\text{nm})^2(0.68\,\text{mm})^2}\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}} = \boxed{2.5\,\text{keV}}$$

69 •• When a surface is illuminated by light of wavelength λ, the maximum kinetic energy of the emitted electrons is 1.20 eV. If the wavelength $\lambda' = 0.800\lambda$ is used, the maximum kinetic energy increases to 1.76 eV. For wavelength $\lambda' = 0.600\lambda$, the maximum kinetic energy of the emitted electrons is 2.676 eV. Determine the work function of the surface and the wavelength λ.

Picture the Problem The maximum kinetic energy of the photoelectrons is related to the frequency of the incident photons and the work function of the illuminated surface through the Einstein equation. We can apply this equation to either set of data and solve the resulting equations simultaneously for the work function of the surface and the wavelength of the incident photons.

Using the Einstein equation, relate the maximum kinetic energy of the emitted electrons to the frequency of the incident photons and the work function of the cathode material:

$$K_{\text{max}} = hf - \phi = \frac{hc}{\lambda} - \phi$$

Substitute numerical values for the light of wavelength λ:

$$1.20\,\text{eV} = \frac{hc}{\lambda} - \phi$$

Substitute numerical values for the light of wavelength λ':

$$1.76\,\text{eV} = \frac{hc}{\lambda'} - \phi = \frac{hc}{0.800\lambda} - \phi$$

Solve these equations simultaneously for ϕ to obtain:

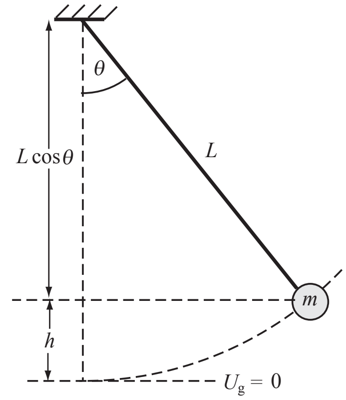
$$\phi = \boxed{1.04\,\text{eV}}$$

Substitute in either of the equations and solve for λ:

$$\lambda = \boxed{554\,\text{nm}}$$

70 •• A simple pendulum has a length equal to 1.0 m and has a bob that has a mass equal to 0.30 kg. The energy of this oscillator is quantized, and the allowed values of the energy are given by $E_n = \left(n + \frac{1}{2}\right)hf_0$, where n is an integer and f_0 is the frequency of the pendulum. (a) Find n if the angular amplitude is 1.0°. (b) Find n such that E_{n+1} exceeds E_n by 0.010 percent.

Picture the Problem The diagram shows the pendulum when its angular displacement is θ. The energy of the oscillator is equal to its initial potential energy $mgh = mgL(1 - \cos\theta)$. We can find n by equating this initial energy to $E_n = \left(n + \frac{1}{2}\right)hf_0$ and solving for n.



(a) Express the nth-state energy as a function of the frequency of the pendulum:

$$E_n = \left(n + \tfrac{1}{2}\right)hf_0$$

Because the small-amplitude frequency of the pendulum is given by $f_0 = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{L}}$:

$$E_n = \left(n + \tfrac{1}{2}\right)\frac{h}{2\pi}\sqrt{\frac{g}{L}}$$

The energy of the pendulum is also equal to its initial gravitational potential energy:

$$E_n = mgL(1 - \cos\theta)$$

Equating these expressions gives:

$$mgL(1 - \cos\theta) = \left(n + \tfrac{1}{2}\right)\frac{h}{2\pi}\sqrt{\frac{g}{L}}$$

Solving for n gives:

$$n = \frac{2\pi m\sqrt{g}L^{3/2}(1 - \cos\theta)}{h} - \frac{1}{2}$$

Substitute numerical values and evaluate n:

$$n = \frac{2\pi(0.30\,\text{kg})\sqrt{9.81\,\text{m/s}^2}\,(1.0\,\text{m})^{3/2}(1 - \cos 1.0°)}{6.626\times10^{-34}\,\text{J}\cdot\text{s}} - \frac{1}{2}$$
$$= 1.357\times10^{30} = \boxed{1.4\times10^{30}}$$

(b) Because E_{n+1} exceeds E_n by 0.010 percent:

$$\frac{E_{n+1} - E_n}{E_n} = 1.0\times10^{-4}$$

Substituting for E_{n+1} and E_n gives:

$$\frac{\left(n+1+\frac{1}{2}\right)hf_0-\left(n+\frac{1}{2}\right)hf_0}{\left(n+\frac{1}{2}\right)hf_0}=1.0\times10^{-4}$$

or

$$\left(n+1+\tfrac{1}{2}\right)-\left(n+\tfrac{1}{2}\right)=1.0\times10^{-4}\left(n+\tfrac{1}{2}\right)$$

Solving for n yields:

$$n=1.0\times10^{4}-\tfrac{1}{2}=\boxed{1.0\times10^{4}}$$

71 •• **[SSM]** (*a*) Show that for large *n*, the fractional difference in energy between state *n* and state *n* + 1 for a particle in a one-dimensional box is given approximately by $\left(E_{n+1}-E_n\right)/E_n\approx 2/n$ (*b*) What is the approximate percentage energy difference between the states n_1 = 1000 and n_2 = 1001? (*c*) Comment on how this result is related to Bohr's correspondence principle.

Picture the Problem We can use the fact that the energy of the *n*th state is related to the energy of the ground state according to $E_n=n^2E_1$ to express the fractional change in energy in terms of *n* and then examine this ratio as *n* grows without bound.

(*a*) Express the ratio $(E_{n+1}-E_n)/E_n$:

$$\frac{E_{n+1}-E_n}{E_n}=\frac{(n+1)^2-n^2}{n^2}=\frac{2n+1}{n^2}$$

$$=\frac{2}{n}+\frac{1}{n^2}\approx\boxed{\frac{2}{n}}$$

for $n >> 1$.

(*b*) Evaluate $\dfrac{E_{1001}-E_{1000}}{E_{1000}}$:

$$\frac{E_{1001}-E_{1000}}{E_{1000}}\approx\frac{2}{1000}=\boxed{0.2\%}$$

(*c*) Classically, the energy is continuous. For very large values of *n,* the energy difference between adjacent levels is infinitesimal.

72 •• A mode-locked, titanium–sapphire laser has a wavelength of 850 nm and produces 100 million pulses of light each second. Each pulse has a duration of 125 femtoseconds (1 fs = 10^{-15} s) and consists of 5×10^9 photons. What is the average power produced by the laser?

Picture the Problem We can apply the definition of power in conjunction with the de Broglie equation for the energy of a photon to derive an expression for the average power produced by the laser.

The average power produced by the laser is:

$$P = \frac{\Delta E}{\Delta t}$$

Use the de Broglie equation to express the energy of the emitted photons:

$$\Delta E = Nhf = \frac{Nhc}{\lambda}$$

where N is number of photons in each pulse.

Substitute for ΔE to obtain:

$$P = \frac{Nhc}{\lambda \Delta t}$$

Substitute numerical values and evaluate P:

$$P = \frac{(5\times10^{9})(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{(850\,\text{nm})(10^{-8}\ \text{s})} \approx \boxed{0.1\,\text{W}}$$

Remarks: Note that the pulse length has no bearing on the solution.

73 •• This problem estimates the time lag in the photoelectric effect that is expected classically but not observed. Let the intensity of the incident radiation falling on an atom be 0.010 W/m^2. (*a*) If the area presented by the atom is 0.010 nm^2, find the energy per second falling on an atom. (*b*) If the work function is 2.0 eV, how long would it take for this much energy to fall on the atom if the radiation energy was distributed uniformly rather than in compact packets (photons)?

Picture the Problem We can find the rate at which energy is delivered to the atom using the definitions of power and intensity. We can also use the definition of power to determine how much time is required for an amount of energy equal to the work function to fall on one atom.

(*a*) Relate the energy per second (power) falling on an atom to the intensity of the incident radiation:

$$P = \frac{\Delta E}{\Delta t} = IA$$

Substitute numerical values and evaluate P:

$$\begin{aligned} P &= (0.010\,\text{W/m}^2)(0.010\times10^{-18}\ \text{m}^2) \\ &= 10^{-22}\ \frac{\text{J}}{\text{s}} \times \frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}} \\ &= 6.242\times10^{-4}\ \text{eV/s} \\ &= \boxed{6.2\times10^{-4}\ \text{eV/s}} \end{aligned}$$

(*b*) Classically:

$$\Delta t = \frac{\Delta E}{P} = \frac{\phi}{P}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2.0\,\text{eV}}{6.242\times10^{-4}\ \text{eV/s}} = 3204\,\text{s}$$

$$\approx \boxed{53\,\text{min}}$$

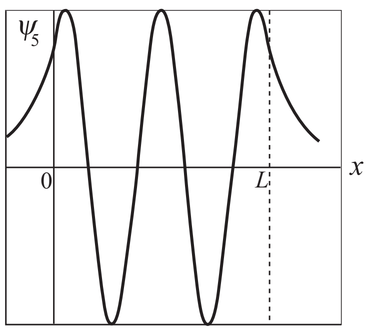
Chapter 35
Applications of the Schrödinger Equation

Conceptual Problems

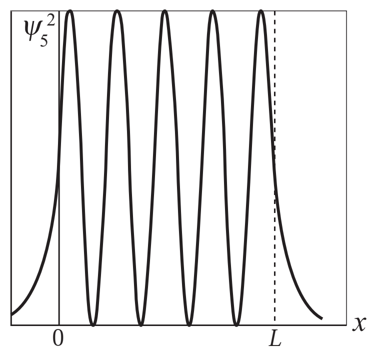
1 • Sketch (*a*) the wave function and (*b*) the probability density function for the $n = 5$ state of the finite square-well potential.

Determine the Concept Looking at the graphs in the text for the $n = 1$, 2, and 3 states, we note that the $n = 5$ state graph of the wave function must have five extrema in the region $0 < x < L$ and decay in toward zero in the regions $x < 0$ and $x > L$.

(*a*)



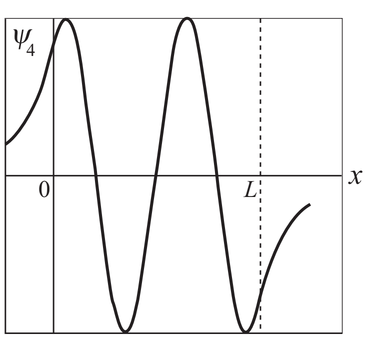
(*b*)



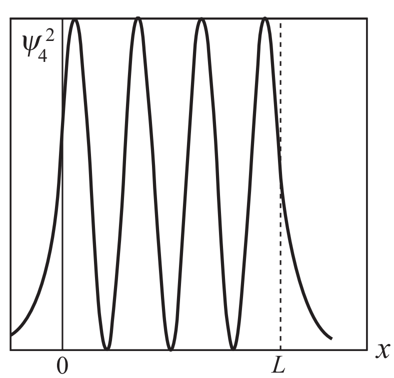
2 • Sketch (*a*) the wave function and (*b*) the probability density function for the $n = 4$ state of the finite square-well potential.

Determine the Concept Looking at the graphs in the text for the $n = 1$, 2, and 3 states, we note that the $n = 4$ state graph of the wave function must have four extrema in the region $0 < x < L$ and decay in toward zero in the regions $x < 0$ and $x > L$.

(*a*)



(*b*)



The Schrödinger Equation

3 •• Show that if $\psi_1(x)$ and $\psi_2(x)$ are each solutions to the time-independent Schrödinger equation (Equation 35-4), then $\psi_3(x) = \psi_1(x) + \psi_2(x)$ is also a solution. This result, known as the superposition principle, applies to the solutions of all linear equations.

Picture the Problem We can show that $\psi_3(x)$ is a solution to the time-independent Schrödinger equation by differentiating it twice and substituting in Equation 35-4.

Equation 35-4 is:

$$-\frac{\hbar^2}{2m}\frac{d^2\psi(x)}{dx^2}+U(x)\psi(x)=E\psi(x)$$

Because $\psi_1(x)$ and $\psi_2(x)$ are solutions of Equation 35-4:

$$-\frac{\hbar^2}{2m}\frac{d^2\psi_1(x)}{dx^2}+U(x)\psi_1(x)=E\psi_1(x)$$

and

$$-\frac{\hbar^2}{2m}\frac{d^2\psi_2(x)}{dx^2}+U(x)\psi_2(x)=E\psi_2(x)$$

Add these equations to obtain:

$$-\frac{\hbar^2}{2m}\left[\frac{d^2\psi_1(x)}{dx^2}+\frac{d^2\psi_2(x)}{dx^2}\right]+U(x)[\psi_1(x)+\psi_2(x)]=E[\psi_1(x)+\psi_2(x)] \quad (1)$$

Differentiate $\psi_3(x)=\psi_1(x)+\psi_2(x)$ twice with respect to x to obtain:

$$\frac{d\psi_3(x)}{dx}=\frac{d\psi_1(x)}{dx}+\frac{d\psi_2(x)}{dx}$$

and

$$\frac{d^2\psi_3(x)}{dx^2}=\frac{d^2\psi_1(x)}{dx^2}+\frac{d^2\psi_2(x)}{dx^2}$$

Substitute in equation (1) to obtain:

$$-\frac{\hbar^2}{2m}\frac{d^2\psi_3(x)}{dx^2}+U(x)\psi_3(x)=E\psi_3(x)$$

which shows that $\psi_3(x)=\psi_1(x)+\psi_2(x)$ satisfies Equation 35-4.

The Harmonic Oscillator

4 •• The harmonic oscillator problem may be used to describe the vibrations of molecules. For example, the hydrogen molecule H_2 is found to have equally spaced vibrational energy levels separated by 8.7×10^{-20} J. What value of the force constant of the spring would be needed to get this energy spacing,

assuming that half the molecule can be modeled as a hydrogen atom attached to one end of a spring that has its other end fixed? Hint: The spacing for the energy levels of this half-molecule would be half of the spacing for the energy levels of the complete molecule. In addition, the force constant of a spring is inversely proportional to its relaxed length, so if half of the spring has force constant *k*, the entire spring has a force constant that is equal to $\frac{1}{2}k$.

Picture the Problem We can relate the spring constant to the mass of the hydrogen atom and its angular frequency and then use the relationship between the allowed energy levels and the angular frequency ω to derive an expression for the force constant *k*.

The force constant *k* is related to the mass *m* of the hydrogen molecule and its angular frequency ω:

$$k = m\omega^2 \qquad (1)$$

Relate the energy spacing ΔE to the angular frequency ω:

$$\Delta E = hf = \frac{h\omega}{2\pi} = \hbar\omega \Rightarrow \omega = \frac{\Delta E}{\hbar}$$

Substitute for ω in equation (1) to obtain:

$$k = m\left(\frac{\Delta E}{\hbar}\right)^2$$

Substitute numerical values and evaluate *k*:

$$k = \left(1\,\text{u} \times \frac{1.661\times10^{-27}\,\text{kg}}{\text{u}}\right)\left(\frac{8.7\times10^{-20}\,\text{J}}{1.055\times10^{-34}\,\text{J}\cdot\text{s}}\right)^2 = \boxed{1.1\,\text{kN/m}}$$

Remarks: Our result is very similar to the stiffness constant of typical macroscopic springs. Note that strictly speaking one should use the reduced mass of a hydrogen molecule rather than the simpler model of a single atom attached to a fixed point.

5 •• [SSM] Use the procedure of Example 35-1 to verify that the energy of the first excited state of the harmonic oscillator is $E_1 = \frac{3}{2}\hbar\omega_0$. (Note: *Rather than solve for a again, use the step-8 result* $a = \frac{1}{2}m\omega_0/\hbar$ *obtained in Example 35-1.)*

Picture the Problem We can differentiate $\psi(x)$ twice and substitute in the Schrödinger equation for the harmonic oscillator. Substitution of the given value for *a* will lead us to an expression for E_1.

The wave function for the first excited state of the harmonic oscillator is:

$$\psi_1(x) = A_1 x e^{-ax^2}$$

Compute $d\psi_1(x)/dx$:

$$\frac{d\psi_1(x)}{dx} = \frac{d}{dx}\left[A_1 x e^{-ax^2}\right] = A_1 e^{-ax^2}$$

Compute $d^2\psi_1(x)/dx^2$:

$$\frac{d^2\psi_1(x)}{dx^2} = \frac{d}{dx}\left[A_1 e^{-ax^2}\right] = -2axA_1e^{-ax^2} - 4axA_1e^{-ax^2} + 4a^2x^3A_1e^{-ax^2}$$
$$= \left(4a^2x^3 - 6ax\right)A_1e^{-ax^2}$$

Substitute in the Schrödinger equation to obtain:

$$-\frac{\hbar^2}{2m}\left[\left(4a^2x^3 - 6ax\right)A_1e^{-ax^2}\right] + \tfrac{1}{2}m\omega_0^2x^2A_1xe^{-ax^2} = E_1A_1xe^{-ax^2}$$

Dividing out $A_1e^{-ax^2}$ (one can do this because the exponential function is never zero) yields:

$$-\frac{\hbar^2}{2m}\left[\left(4a^2x^3 - 6ax\right)\right] + \tfrac{1}{2}m\omega_0^2x^3 = E_1x$$

or

$$-\frac{\hbar^2}{2m}\left(4a^2x^3\right) + \frac{\hbar^2}{2m}(6ax) + \tfrac{1}{2}m\omega_0^2x^3 = E_1x$$

Substitute for a to obtain:

$$-\frac{\hbar^2}{2m}4\left(\frac{m\omega_0}{2\hbar}\right)^2x^3 + \frac{\hbar^2}{2m}6\left(\frac{m\omega_0}{2\hbar}\right)x + \tfrac{1}{2}m\omega_0^2x^3 = E_1x$$

Solve for E_1 to obtain:

$$E_1 = \boxed{\tfrac{3}{2}\hbar\omega_0} = 3E_0$$

6 •• Show that the expectation value $< x >= \int x|\psi|^2 dx$ is zero for both the ground state and the first excited state of the harmonic oscillator.

Determine the Concept The integral $\langle x\rangle = \int x|\psi|^2 dx = 0$ because the integrand is an odd function of x for the ground state as well as any excited state of the harmonic oscillator.

7 •• Verify that the normalization constant A_0 in the ground-state harmonic-oscillator wave function $\psi_0(x) = A_0 e^{-ax^2}$ (Equation 35-23) is given by $A_0 = (2m\omega_0/h)^{1/4}$.

Picture the Problem We must show that if $\int_{-\infty}^{\infty} |\psi_0(x)|^2 dx = \int_{-\infty}^{\infty} \left|A_0 e^{-ax^2}\right|^2 dx = 1$, then $A_0 = (2m\omega_0/h)^{1/4}$.

We need to show that:

$$\int_{-\infty}^{\infty} \left|A_0 e^{-ax^2}\right|^2 dx = A_0^2 \int_{-\infty}^{\infty} e^{-2ax^2} dx = 1$$

Because $\int_{-\infty}^{\infty} e^{-2ax^2} dx = 2\int_{0}^{\infty} e^{-2ax^2} dx$:

$$A_0^2 \int_{-\infty}^{\infty} e^{-2ax^2} dx = 2A_0^2 \int_{0}^{\infty} e^{-2ax^2} dx$$

Letting $b = 2a$ yields:

$$2A_0^2 \int_{0}^{\infty} e^{-bx^2} dx = 1$$

From integral tables (see Table D-5):

$$\int_{0}^{\infty} e^{-bx^2} dx = \frac{1}{2}\sqrt{\frac{\pi}{b}} = \frac{1}{2}\sqrt{\frac{\pi}{2a}}$$

Substituting for $\int_{0}^{\infty} e^{-bx^2} dx$ gives:

$$2A_0^2 \left(\frac{1}{2}\sqrt{\frac{\pi}{2a}}\right) = 1$$

or

$$A_0^2 \sqrt{\frac{\pi}{2a}} = 1$$

Solving for A_0 yields:

$$A_0 = \left(\frac{2a}{\pi}\right)^{1/4}$$

From Example 35-1:

$$a = \frac{m\omega_0}{2\hbar}$$

Substitute for a to obtain:

$$A_0 = \left(\frac{2m\omega_0}{2\hbar\pi}\right)^{1/4} = \boxed{\left(\frac{2m\omega_0}{h}\right)^{1/4}}$$

8 •• Using the result of Problem 7, show that for the ground state of the harmonic oscillator $\langle x^2 \rangle = \int x^2 |\psi|^2 dx = h/(2m\omega_0) = 1/(4a)$. Use this result to show that the average potential energy equals half the total energy.

Picture the Problem We are required to evaluate $\langle x^2 \rangle = \int x^2 |\psi_0(x)|^2$ with $\psi_0(x) = A_0 e^{-ax^2}$, where $a = \dfrac{m\omega_0}{2\hbar}$. We can then use $U_{\text{av}} = \frac{1}{2} m\omega_0^2 \langle x^2 \rangle$ to find the average potential energy of the harmonic oscillator.

We need to evaluate:

$$\langle x^2 \rangle = \int_{-\infty}^{+\infty} x^2 |\psi|^2 dx$$

For the ground state of the harmonic oscillator:

$$|\psi|^2 = A_0^2 e^{-2ax^2}$$

Substitute for $|\psi|^2$ to obtain:

$$\langle x^2 \rangle = A_0^2 \int_{-\infty}^{+\infty} x^2 e^{-2ax^2} dx$$
$$= 2A_0^2 \int_0^{+\infty} x^2 e^{-2ax^2} dx$$

Use the appropriate integral from the inside of the back cover of the text to obtain:

$$\langle x^2 \rangle = 2A_0^2 \frac{1}{4}\sqrt{\frac{\pi}{(2a)^3}} = \frac{A_0^2}{4a}\sqrt{\frac{\pi}{2a}} \qquad (1)$$

The normalization condition is:

$$1 = \int_{-\infty}^{+\infty} |\psi|^2 dx = A_0^2 \int_{-\infty}^{+\infty} e^{-2ax^2} dx$$
$$= 2A_0^2 \int_0^{+\infty} e^{-2ax^2} dx$$

Again, use the appropriate integral from the inside of the back cover of the text to obtain:

$$1 = 2A_0^2 \frac{1}{2}\sqrt{\frac{\pi}{2a}} = A_0^2 \sqrt{\frac{\pi}{2a}}$$

Solving for A_0^2 yields:

$$A_0^2 = \sqrt{\frac{2a}{\pi}}$$

Substitute in equation (1) to obtain:

$$\langle x^2 \rangle = \frac{1}{4a}\sqrt{\frac{2a}{\pi}}\sqrt{\frac{\pi}{2a}} = \boxed{\frac{1}{4a}} \qquad (2)$$

From Example 36-1: $a = \frac{m\omega_0}{2\hbar}$

Substitute for a in equation (2) to obtain: $\langle x^2 \rangle = \frac{2\hbar}{4m\omega_0} = \boxed{\frac{\hbar}{2m\omega_0}}$

The average potential energy of the oscillator is: $U_{\text{av}} = \frac{1}{2} m\omega_0^2 \langle x^2 \rangle$

Substitute for $\langle x^2 \rangle$ and simplify:

$$U_{\text{av}} = \frac{1}{2} m\omega_0^2 \left(\frac{\hbar}{2m\omega_0} \right) = \boxed{\tfrac{1}{4}\hbar\omega_0}$$
$$= \tfrac{1}{2} E_0$$

9 •• The quantity $\sqrt{<x^2> - <x>^2}$ is a measure of the average spread in the location of a particle. (*a*) Consider an electron trapped in a harmonic oscillator potential. Its lowest energy level is found to be 2.1×10^{-4} eV. Calculate $\sqrt{<x^2> - <x>^2}$ for this electron. (See Problems 6 and 8.) (*b*) Now consider an electron trapped in an infinite square-well potential. If the width of the well is equal to $\sqrt{<x^2> - <x>^2}$, what would be the lowest energy level for this electron?

Picture the Problem We can combine the result for $\sqrt{\langle x^2 \rangle}$ from Problem 8 and the result for $\langle x \rangle$ from Problem 6 to obtain an expression for $\sqrt{\langle x^2 \rangle - \langle x \rangle^2}$. The lowest energy of the electron in an infinite potential well is given by $E_1 = \frac{h^2}{8mL^2}$.

(*a*) From Problem 8 we have: $\langle x^2 \rangle = \frac{\hbar}{2m\omega_0}$ (1)

The ground-state energy is given by: $E_0 = \frac{1}{2}\hbar\omega_0 \Rightarrow \omega_0 = \frac{2E_0}{\hbar}$

Substitute in equation (1) and simplify to obtain: $\langle x^2 \rangle = \frac{\hbar^2}{4mE_0}$

From Problem 6 we have: $\langle x \rangle = 0$ (2)

Substitute equations (1) and (2) in the expression $\sqrt{\langle x^2\rangle - \langle x\rangle^2}$ to obtain:

$$\sqrt{\langle x^2\rangle - \langle x\rangle^2} = \sqrt{\frac{\hbar^2}{4mE_0} - 0} = \frac{\hbar}{2}\sqrt{\frac{1}{mE_0}}$$

Substitute numerical values and evaluate $\sqrt{\langle x^2\rangle - \langle x\rangle^2}$:

$$\sqrt{\langle x^2\rangle - \langle x\rangle^2} = \frac{1.055\times10^{-34}\ \text{J}\cdot\text{s}}{2}\sqrt{\frac{1}{(9.109\times10^{-31}\ \text{kg})\left(2.1\times10^{-4}\ \text{eV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)}}$$

$$= 9.53\,\text{nm} = \boxed{9.5\,\text{nm}}$$

(*b*) The lowest energy of an electron trapped in an infinite potential well is:

$$E_1 = \frac{h^2}{8mL^2}$$

Letting $L = \sqrt{\langle x^2\rangle - \langle x\rangle^2}$ yields:

$$E_1 = \frac{h^2}{8m\left(\sqrt{\langle x^2\rangle - \langle x\rangle^2}\right)^2}$$

Substitute numerical values and evaluate E_1:

$$E_1 = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})^2}{8(9.109\times10^{-31}\ \text{kg})(9.53\times10^{-9}\ \text{m})^2}\frac{1\,\text{eV}}{1.602\times10^{-19}\ \text{J}} = \boxed{4.1\,\text{meV}}$$

10 ••• Classically, the average kinetic energy of the harmonic oscillator equals the average potential energy. Assume that this result is also true for the quantum mechanical harmonic oscillator, and use this result, along with the result of Problem 8, to determine the expectation value of p_x^2 (where $p_x = mv_x$) for the ground state of the harmonic oscillator.

Picture the Problem We can begin by equating the average kinetic energy of the harmonic oscillator and its average potential energy and solving for $\langle p_x^2\rangle$ and then evaluating and substituting for $\langle x^2\rangle$.

According to the problem statement:

$$\frac{\langle p_x^2\rangle}{2m} = \frac{1}{2}k\langle x^2\rangle \Rightarrow \langle p_x^2\rangle = mk\langle x^2\rangle$$

Because $\omega_0^2 = \dfrac{k}{m}$:

$$\left\langle p_x^2 \right\rangle = m^2\omega_0^2 \left\langle x^2 \right\rangle \qquad (1)$$

We need to evaluate:

$$\left\langle x^2 \right\rangle = \int x^2 |\psi|^2 = A_0^2 \int_{-\infty}^{\infty} x^2 e^{-2ax^2}\,dx \qquad (2)$$

where $a = \dfrac{m\omega_0}{2\hbar}$

Let $y^2 = 2ax^2$. Then $x^2 = \dfrac{y^2}{2a}$ and:

$$dx = \frac{ydy}{2ax}$$

With appropriate substitutions, the integral becomes:

$$\int_{-\infty}^{\infty} \frac{y^2}{2a} e^{-y^2} \frac{ydy}{2ax} = \int_{-\infty}^{\infty} \frac{y^3}{2a} e^{-y^2} \frac{\sqrt{2a}dy}{2ay} = \frac{1}{(2a)^{3/2}} \int_{-\infty}^{\infty} y^2 e^{-y^2} dy$$

From integral tables (see Table D-5):

$$\int_{-\infty}^{\infty} y^2 e^{-y^2} dy = \frac{1}{2}\sqrt{\pi}$$

In Problem 7 it was given that:

$$A_0 = \left(\frac{2m\omega_0}{h}\right)^{1/4}$$

Substituting in equation (2) yields:

$$\left\langle x^2 \right\rangle = \frac{1}{(2a)^{3/2}} \left(\frac{2m\omega_0}{h}\right)^{1/2} \left(\frac{1}{2}\sqrt{\pi}\right)$$

Substitute for a and simplify:

$$\left\langle x^2 \right\rangle = \frac{1}{\left(\frac{m\omega_0}{\hbar}\right)^{3/2}} \left(\frac{2m\omega_0}{h}\right)^{1/2} \left(\frac{1}{2}\sqrt{\pi}\right)$$

$$= \frac{\hbar}{2m\omega_0}$$

Substitute for $\left\langle x^2 \right\rangle$ in equation (1) and simplify to obtain:

$$\left\langle p_x^2 \right\rangle = m^2\omega_0^2 \left(\frac{\hbar}{2m\omega_0}\right) = \boxed{\tfrac{1}{2}\hbar m\omega_0}$$

11 ••• We know that for the classical harmonic oscillator, $p_{x,\,\mathrm{av}} = 0$. It can be shown that for the quantum mechanical harmonic oscillator, $\left\langle p_x \right\rangle = 0$. Use the results of Problem 6, Problem 8, and Problem 10 to determine the uncertainty

product $\Delta x\ \Delta p_x$ for the ground state of the harmonic oscillator. The uncertainties are defined by $(\Delta x)^2 = \left\langle \left(x - \langle x \rangle\right)^2 \right\rangle$ and $(\Delta p_x)^2 = \left\langle \left(p_x - \langle p_x \rangle\right)^2 \right\rangle$.

Picture the Problem We can use the definition of the standard deviation as the uncertainty of Δx and Δp and the results of Problems 6, 8, and 10 to determine the uncertainty product $\Delta x\ \Delta p$ for the ground state of the harmonic oscillator.

The square of the uncertainty of Δp is given by:

$$\begin{aligned}(\Delta p_x)^2 &= \left\langle \left(p_x - \langle p_x \rangle\right)^2 \right\rangle \\ &= \left\langle p_x^2 - 2p_x\langle p_x \rangle + \langle p_x \rangle^2 \right\rangle \\ &= \left\langle p_x^2 \right\rangle - 2\langle p_x \rangle\langle p_x \rangle + \langle p_x \rangle^2 \\ &= \left\langle p_x^2 \right\rangle - \langle p_x \rangle^2\end{aligned}$$

or, because $\langle p_x \rangle = 0$,

$$(\Delta p_x)^2 = \left\langle p_x^2 \right\rangle$$

Similarly, the square of the uncertainty of Δx is given by:

$$(\Delta x)^2 = \left\langle x^2 \right\rangle - \langle x \rangle^2$$

or, because $\langle x \rangle = 0$ (Problem 6),

$$(\Delta x)^2 = \left\langle x^2 \right\rangle$$

We have (from Problems 8 and 10) for the ground state of the harmonic oscillator:

$$\left\langle x^2 \right\rangle = (\Delta x)^2 = \frac{\hbar}{2m\omega_0}$$

and

$$\left\langle p^2 \right\rangle = (\Delta p)^2 = \frac{\hbar m\omega_0}{2}$$

Express the product of $(\Delta x)^2$ and $(\Delta p)^2$:

$$(\Delta x)^2 (\Delta p)^2 = \left(\frac{\hbar}{2m\omega_0}\right)\left(\frac{\hbar m\omega_0}{2}\right) = \frac{\hbar^2}{4}$$

Take the square root of both sides of the equation to obtain:

$$\boxed{\Delta x \Delta p = \frac{\hbar}{2}}$$

Reflection and Transmission of Electron Waves: Barrier Penetration

12 •• A particle of energy E approaches a step barrier of height U_0. What should be the ratio E/U_0 so that the reflection coefficient is 1/2?

Picture the Problem We can use the energies in the regions $U = 0$ and $U = U_0$ to express the ratio of the potential energy to the total energy in terms of the ratio of the wave numbers. We can also express this ratio in terms of the reflection coefficient R to obtain an expression for the ratio of E to U in terms of R.

In the region $U = 0$:

$$E = \frac{\hbar^2 k_1^2}{2m} \Rightarrow k_1 = \sqrt{\frac{2mE}{\hbar^2}}$$

In the region $U = U_0$:

$$E - U_0 = \frac{\hbar^2 k_2^2}{2m} \Rightarrow k_2 = \sqrt{\frac{2m(E-U_0)}{\hbar^2}}$$

Let r equal the ratio of k_2 to k_1:

$$r = \frac{k_2}{k_1} = \frac{\sqrt{\frac{2m(E-U_0)}{\hbar^2}}}{\sqrt{\frac{2mE}{\hbar^2}}} = \sqrt{1 - \frac{U_0}{E}}$$

Letting $U_0 = U$, solve for U/E:

$$\frac{U}{E} = 1 - r^2 \qquad (1)$$

Write the reflection coefficient R as a function of $r = \frac{k_2}{k_1}$:

$$R = \frac{(k_1 - k_2)^2}{(k_1 + k_2)^2} = \frac{\left(1 - \frac{k_2}{k_1}\right)^2}{\left(1 + \frac{k_2}{k_1}\right)^2} = \frac{(1-r)^2}{(1+r)^2}$$

Solving for r gives:

$$r = \frac{1 - \sqrt{R}}{1 + \sqrt{R}}$$

Substitute for r in equation (1):

$$\frac{U}{E} = 1 - \left(\frac{1 - \sqrt{R}}{1 + \sqrt{R}}\right)^2$$

and

$$\frac{E}{U} = \left[1 - \left(\frac{1 - \sqrt{R}}{1 + \sqrt{R}}\right)^2\right]^{-1}$$

Substitute a numerical value for R and evaluate E/U:

$$\frac{E}{U} = \left[1 - \left(\frac{1 - \sqrt{0.5}}{1 + \sqrt{0.5}}\right)^2\right]^{-1} = \boxed{1.03}$$

13 •• [SSM] A particle that has mass m is traveling in the direction of increasing x. The potential energy of the particle is equal to zero everywhere in the region $x < 0$ and is equal to U_0 everywhere in the region $x > 0$, where $U_0 > 0$. (*a*) Show that if the total energy is $E = \alpha U_0$, where $\alpha \geq 1$, then the wave number k_2 in the region $x > 0$ is given by $k_2 = k_1\sqrt{(\alpha - 1)/\alpha}$, where k_1 is the wave number in the region $x < 0$. (*b*) Using a **spreadsheet** program or graphing calculator, graph the reflection coefficient R and the transmission coefficient T as functions of α, for $1 \leq \alpha \leq 5$.

Picture the Problem We can use the total energy of the particle in the region $x > 0$ to express k_2 in terms of α and k_1. Knowing k_2 in terms of k_1, we can use $R = \frac{(k_1 - k_2)^2}{(k_1 + k_2)^2}$ to find R and $T = 1 - R$ to determine the transmission coefficient T.

(*a*) Using conservation of energy, express the energy of the particle in the region $x > 0$:

$$\frac{\hbar^2 k_2^2}{2m} + U_0 = \alpha U_0$$

Solving for k_2 gives:

$$k_2 = \frac{\sqrt{2mU_0(\alpha - 1)}}{\hbar}$$

From the equation for the total energy of the particle:

$$k_1 = \frac{\sqrt{2m\alpha U_0}}{\hbar}$$

Express the ratio of k_2 to k_1:

$$\frac{k_2}{k_1} = \frac{\frac{\sqrt{2mU_0(\alpha - 1)}}{\hbar}}{\frac{\sqrt{2m\alpha U_0}}{\hbar}} = \sqrt{\frac{\alpha - 1}{\alpha}}$$

and $k_2 = \boxed{\sqrt{\frac{\alpha - 1}{\alpha}}k_1}$

(*b*) The reflection coefficient R is given by:

$$R = \frac{(k_1 - k_2)^2}{(k_1 + k_2)^2}$$

Factor k_1 from the numerator and denominator to obtain:

$$R = \frac{\left(1 - \frac{k_2}{k_1}\right)^2}{\left(1 + \frac{k_2}{k_1}\right)^2}$$

Substitute the result from Part (a) for k_2/k_1:

$$R = \frac{\left(1-\sqrt{\frac{\alpha-1}{\alpha}}\right)^2}{\left(1+\sqrt{\frac{\alpha-1}{\alpha}}\right)^2} = \left(\frac{1-\sqrt{\frac{\alpha-1}{\alpha}}}{1+\sqrt{\frac{\alpha-1}{\alpha}}}\right)^2$$

The transmission coefficient is given by:

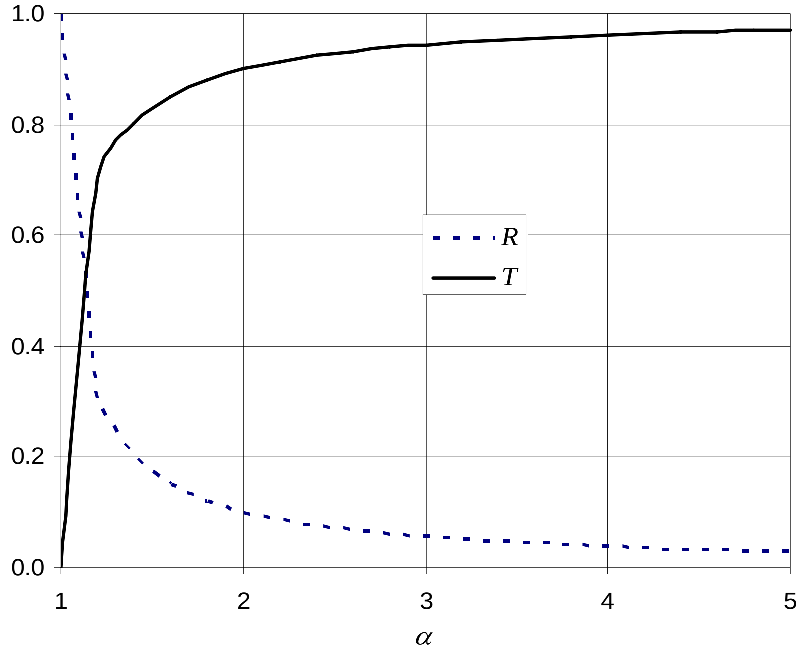
$$T = 1-R = 1-\left(\frac{1-\sqrt{\frac{\alpha-1}{\alpha}}}{1+\sqrt{\frac{\alpha-1}{\alpha}}}\right)^2$$

A spreadsheet program to plot R and T as functions of α is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A2	1.0	α
B2	(1−SQRT((A2−1)/A2))/ (1+SQRT((A2−1)/A2))^2	$\left(\frac{1-\sqrt{\frac{\alpha-1}{\alpha}}}{1+\sqrt{\frac{\alpha-1}{\alpha}}}\right)^2$
C2	1−B2	$1-\left(\frac{1-\sqrt{\frac{\alpha-1}{\alpha}}}{1+\sqrt{\frac{\alpha-1}{\alpha}}}\right)^2$

	A	B	C
1	α	R	T
2	1.0	1.000	0.000
3	1.2	0.298	0.702
4	1.4	0.198	0.802
5	1.6	0.149	0.851
18	4.2	0.036	0.964
19	4.4	0.034	0.966
20	4.6	0.032	0.968
21	4.8	0.031	0.969
22	5.0	0.029	0.971

The following graph was plotted using the data in the above table:



14 •• Suppose that the potential energy in Problem 13 is equal to zero everywhere in the region $x < 0$ and is equal to $-U_0$ everywhere in the region $x > 0$, where $U_0 > 0$. The wave number for the incident particle is again k_1, and the total energy is $2U_0$. (*a*) What is the wave number for the particle in the region where $x > 0$? (*b*) What is the reflection coefficient *R*? (*c*) What is the transmission coefficient *T*? (*d*) If each of one million particles that are in the region $x < 0$ are traveling with wave number k_1 in the direction of increasing *x* are incident upon the potential energy drop at $x = 0$, how many of these particles are expected to continue along in the direction of increasing *x*? How does this compare with the classical prediction?

Picture the Problem We can use the total energy of the particle in the region $x > 0$ to find k_2. Knowing k_2, we can use $R = \frac{(k_1 - k_2)^2}{(k_1 + k_2)^2}$ to find *R* and $T = 1 - R$ to determine the transmission coefficient *T*.

(*a*) Using conservation of energy, express the particle in the region $x > 0$:

$$\frac{\hbar^2 k_2^2}{2m} - U_0 = 2U_0 \Rightarrow k_2 = \frac{\sqrt{6mU_0}}{\hbar}$$

From the equation for the total energy of the particle:

$$k_1 = \frac{\sqrt{4mU_0}}{\hbar}$$

Express the ratio of k_2 to k_1 and solve for k_2 to obtain:

$$\frac{k_2}{k_1}=\frac{\frac{\sqrt{6mU_0}}{\hbar}}{\frac{\sqrt{4mU_0}}{\hbar}}=\sqrt{\frac{3}{2}}\Rightarrow k_2=\boxed{\sqrt{\frac{3}{2}}k_1}$$

(b) The reflection coefficient R is given by:

$$R=\frac{(k_1-k_2)^2}{(k_1+k_2)^2}=\frac{\left(1-\frac{k_2}{k_1}\right)^2}{\left(1+\frac{k_2}{k_1}\right)^2}$$

Substitute for k_2/k_1 and evaluate R:

$$R=\frac{\left(1-\sqrt{\frac{3}{2}}\right)^2}{\left(1+\sqrt{\frac{3}{2}}\right)^2}=\boxed{0.0102}$$

(c) Because $R+T=1$:

$$T=1-R=1-0.0102=\boxed{0.990}$$

(d) If we let N_0 represent the number of particles incident upon the potential step, then the number that continue beyond is:

$$N_0T=10^6\times 0.990=\boxed{9.90\times 10^5}$$

Classically, all 10^6 would continue to move past the potential step.

15 •• [SSM] A 10-eV electron (an electron with a kinetic energy of 10 eV) is incident on a potential-energy barrier that has a height equal to 25 eV and a width equal to 1.0 nm. (a) Use Equation 35-29 to calculate the order of magnitude of the probability that the electron will tunnel through the barrier. (b) Repeat your calculation for a width of 0.10 nm.

Picture the Problem The probability that the electron with a given energy will tunnel through the given barrier is given by Equation 35-29.

(a) Equation 35-29 is:

$$T\propto e^{-2\alpha a}$$

where

$$\alpha=\sqrt{\frac{2m(U_0-E)}{\hbar^2}}=\frac{\sqrt{2m(U_0-E)}}{\hbar}$$

Multiply the numerator and denominator of α by c to obtain:

$$\alpha = \frac{\sqrt{2mc^2(U_0 - E)}}{\hbar c}$$

where

$$\hbar c = 1.974\times10^{-13}\ \mathrm{MeV\cdot m}$$

Using $m_e c^2 = 511\,\mathrm{keV}$, evaluate T:

$$T \propto \exp\left\{-2\left(1.0\times10^{-9}\ \mathrm{m}\right)\frac{\sqrt{2(511\,\mathrm{keV})(25\,\mathrm{eV}-10\,\mathrm{eV})}}{1.974\times10^{-13}\ \mathrm{MeV\cdot m}}\right\} = 5.9\times10^{-18} \approx \boxed{10^{-17}}$$

(b) Repeat with a = 0.10 nm:

$$T \propto \exp\left\{-2\left(0.10\times10^{-9}\ \mathrm{m}\right)\frac{\sqrt{2(511\,\mathrm{keV})(25\,\mathrm{eV}-10\,\mathrm{eV})}}{1.974\times10^{-13}\ \mathrm{MeV\cdot m}}\right\} = 1.9\times10^{-2} \approx \boxed{10^{-2}}$$

16 •• Use Equation 35-29 to calculate the order of magnitude of the probability that a proton will tunnel out of a nucleus in one collision with the nuclear barrier if the proton has an energy 6.0 MeV below the top of the potential-energy barrier and the barrier thickness is 1.2×10^{-15} m.

Picture the Problem The probability that a proton will tunnel out of a nucleus in one collision with a nuclear barrier if it has a given energy is given by Equation 35-29.

Equation 35-29 is:

$$T \propto e^{-2\alpha a}$$

where

$$\alpha = \sqrt{\frac{2m(U_0 - E)}{\hbar^2}} = \frac{\sqrt{2m(U_0 - E)}}{\hbar}$$

Multiply the numerator and denominator of α by c to obtain:

$$\alpha = \frac{\sqrt{2mc^2(U_0 - E)}}{\hbar c}$$

where

$$\hbar c = 1.974\times10^{-13}\ \mathrm{MeV\cdot m}$$

Using $m_p c^2 = 938\,\mathrm{MeV}$, evaluate T:

$$T \propto \exp\left\{-2\left(1.2\times10^{-15}\ \mathrm{m}\right)\frac{\sqrt{2(938\,\mathrm{MeV})(6.0\,\mathrm{MeV})}}{1.974\times10^{-13}\ \mathrm{MeV\cdot m}}\right\} = 0.275 \approx \boxed{10^{-1}}$$

17 ••• To understand how a small change in α-particle energy can dramatically change the probability of the α particle tunneling from a nucleus, consider an α particle emitted by a uranium nucleus ($Z = 92$). (*a*) Referring to Figure 35-17, calculate the center-to-center distance of closest approach r_1 that α particles that have kinetic energies of 4.0 MeV and 7.0 MeV could make to the uranium nucleus. (*b*) Use the result from Part (*a*) to calculate the relative transmission coefficient $e^{-2\alpha a}$ for the same α particles. (Note: *The actual half-lives of uranium nuclei vary over nine orders of magnitude. Your calculation will show a smaller range than this; however, to find half-life, you must also include the frequency with which the α particle strikes the barrier.*)

Picture the Problems We can find the distance of closest approach by equating the kinetic energy of the alpha particle and the Coulomb potential energy. The probability that the electron with a given energy will tunnel through the given barrier is given by $T \propto e^{-2\alpha a}$ where α is the transmission coefficient and depends on ΔE.

(*a*) The distance of closest approach is related to the kinetic energy E of the alpha particles:

$$E = \frac{k2eZe}{r_1} \Rightarrow r_1 = \frac{2kZe^2}{E}$$

For $E = 4.0$ MeV:

$$r_{1,4.0\,\text{MeV}} = \frac{2\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(92)\left(1.602\times10^{-19}\ \text{C}\right)^2}{4.0\,\text{MeV}\times\dfrac{1.602\times10^{-19}\ \text{J}}{\text{eV}}} = 6.623\times10^{-14}\ \text{m}$$

$$= \boxed{66\,\text{fm}}$$

For $E = 7.0$ MeV:

$$r_{1,7.0\,\text{MeV}} = \frac{2\left(8.988\times10^9\ \text{N}\cdot\text{m}^2/\text{C}^2\right)(92)\left(1.602\times10^{-19}\ \text{C}\right)^2}{7.0\,\text{MeV}\times\dfrac{1.602\times10^{-19}\ \text{J}}{\text{eV}}} = 3.785\times10^{-14}\ \text{m}$$

$$= \boxed{38\,\text{fm}}$$

(*b*) The transmission coefficient T is given by:

$$T \propto e^{-2\alpha a} \qquad (1)$$

where

$$\alpha = \sqrt{\frac{2m\Delta E}{\hbar^2}} = \frac{\sqrt{2m\Delta E}}{\hbar}$$

Evaluate $\alpha_{4.0\text{ MeV}}$ for ΔE = 4.0 MeV:

$$\alpha_{4.0\,\text{MeV}} = \frac{\sqrt{2\left(4\,\text{u}\times\frac{1.661\times10^{-27}\,\text{kg}}{\text{u}}\right)\left(4.0\,\text{MeV}\times\frac{1.602\times10^{-19}\,\text{J}}{\text{eV}}\right)}}{1.055\times10^{-34}\,\text{J}\cdot\text{s}} = 8.747\times10^{14}\,\text{m}^{-1}$$

Evaluate $\alpha_{7.0\text{ MeV}}$ for ΔE = 7.0 MeV:

$$\alpha_{7.0\,\text{MeV}} = \frac{\sqrt{2\left(4\,\text{u}\times\frac{1.661\times10^{-27}\,\text{kg}}{\text{u}}\right)\left(7.0\,\text{MeV}\times\frac{1.602\times10^{-19}\,\text{J}}{\text{eV}}\right)}}{1.055\times10^{-34}\,\text{J}\cdot\text{s}} = 1.157\times10^{15}\,\text{m}^{-1}$$

Substitute numerical values in equation (1) and evaluate $T_{4.0\text{ MeV}}$ for $a = r_{1,4.0\,\text{MeV}}$:

$$T_{4.0\,\text{MeV}} \propto \exp\left[-2\left(8.747\times10^{14}\,\text{m}^{-1}\right)\left(6.623\times10^{-14}\,\text{m}\right)\right] \approx \boxed{10^{-51}}$$

Substitute numerical values in equation (1) and evaluate $T_{7.0\text{ MeV}}$ for $a = r_{1,7.0\,\text{MeV}}$:

$$T_{7.0\,\text{MeV}} \propto \exp\left[-2\left(1.157\times10^{15}\,\text{m}^{-1}\right)\left(3.785\times10^{-14}\,\text{m}\right)\right] \approx \boxed{10^{-38}}$$

The Schrödinger Equation in Three Dimensions

18 •• (*a*) A particle is confined to a three-dimensional box that has sides L_1, $L_2 = 2L_1$, and $L_3 = 3L_1$. Give the quantum numbers n_1, n_2 and n_3 that correspond to the ten lowest-energy quantum states of this box. (Hint: *A spreadsheet can be helpful.*) (*b*) What quantum numbers, if any, correspond to degenerate energy levels? (*c*) Give a wave function for the fifth excited state. (There are only five states that have energy levels below the energy level of the fifth excited state.)

Picture the Problem (*a*) The allowed energies of the particle, as a function of the lengths L_1, L_2 and L_3 of the box and the quantum numbers n_1, n_2 and n_3 are given by $E_{n_1,n_2,n_3} = \frac{\hbar^2\pi^2}{2m}\left(\frac{n_1^2}{L_1^2}+\frac{n_2^2}{L_2^2}+\frac{n_3^2}{L_3^2}\right)$. (*b*) Degenerate energy levels correspond to sets of quantum numbers that have the same energy. (*c*) The wave functions are of the form $\psi = A\sin\left(\frac{n_1\pi}{L_1}x\right)\sin\left(\frac{n_2\pi}{2L_1}y\right)\sin\left(\frac{n_3\pi}{3L_1}z\right)$.

(*a*) The energies of the quantum states are given by Equation 35-34:

$$E_{n_1,n_2,n_3} = \frac{\hbar^2\pi^2}{2m}\left(\frac{n_1^2}{L_1^2}+\frac{n_2^2}{L_2^2}+\frac{n_3^2}{L_3^2}\right)$$

For a box with sides L_1, $L_2 = 2L_1$, and $L_3 = 3L_1$:

$$E_{n_1,n_2,n_3} = \frac{\hbar^2\pi^2}{2m}\left(\frac{n_1^2}{L_1^2}+\frac{n_2^2}{4L_1^2}+\frac{n_3^2}{9L_1^2}\right)$$
$$= \frac{h^2}{8mL_1^2}\left(n_1^2+\frac{n_2^2}{4}+\frac{n_3^2}{9}\right)$$
$$= \frac{h^2}{288mL_1^2}\left(36n_1^2+9n_2^2+n_3^2\right)$$

The energies in units of $\frac{h^2}{288mL_1^2}$ are listed in the following table (generated using a spreadsheet program):

n_1	1	1	1	1	1	1	1	1	1	1
n_2	1	1	1	1	1	2	2	1	2	2
n_3	1	2	3	4	5	1	2	6	3	4
E	46	49	54	61	70	73	76	81	81	88

(*b*) The quantum numbers that correspond to degenerate energy levels are $\boxed{(1,1,6)}$ and $\boxed{(1,2,3)}$.

(*c*) For the fifth excited state, $(n_1, n_2, n_3) = (1, 2, 1)$ and the wave function is:

$$\psi(1,2,1) = \boxed{A\sin\left(\frac{\pi}{L_1}x\right)\sin\left(\frac{\pi}{L_1}y\right)\sin\left(\frac{\pi}{3L_1}z\right)}$$

19 •• (*a*) A particle is confined to a three-dimensional box that has sides L_1, $L_2 = 2L_1$, and $L_3 = 4L_1$. Give the quantum numbers n_1, n_2 and n_3 that correspond to the ten lowest-energy quantum states of this box. (Hint: *A spreadsheet can be helpful.*) (*b*) What combinations of these quantum numbers, if any, correspond to degenerate energy levels? (*c*) Give the wave function for the fourth excited energy state. (There are only four states that have energy levels below the energy level of the fourth excited state.)

Picture the Problem (*a*) The allowed energies of the particle, as a function of the lengths L_1, L_2 and L_3 of the box and the quantum numbers n_1, n_2 and n_3 are given by $E_{n_1,n_2,n_3} = \frac{\hbar^2\pi^2}{2m}\left(\frac{n_1^2}{L_1^2}+\frac{n_2^2}{L_2^2}+\frac{n_3^2}{L_3^2}\right)$. (*b*) Degenerate energy levels correspond to

sets of quantum numbers that have the same energy. (*c*) The wave functions are of the form $\psi = A\sin\left(\frac{n_1\pi}{L_1}x\right)\sin\left(\frac{n_2\pi}{2L_1}y\right)\sin\left(\frac{n_3\pi}{4L_1}z\right)$.

(*a*) The energies of the quantum states are given by Equation 35-34:

$$E_{n_1,n_2,n_3} = \frac{\hbar^2\pi^2}{2m}\left(\frac{n_1^2}{L_1^2}+\frac{n_2^2}{L_2^2}+\frac{n_3^2}{L_3^2}\right)$$

For a box with sides L_1, $L_2 = 2L_1$, and $L_3 = 4L_1$:

$$E_{n_1,n_2,n_3} = \frac{\hbar^2\pi^2}{2m}\left(\frac{n_1^2}{L_1^2}+\frac{n_2^2}{4L_1^2}+\frac{n_3^2}{16L_1^2}\right) = \frac{h^2}{8mL_1^2}\left(n_1^2+\frac{n_2^2}{4}+\frac{n_3^2}{16}\right) = \frac{h^2}{128mL_1^2}\left(16n_1^2+4n_2^2+n_3^2\right)$$

The energies in units of $\frac{h^2}{128mL_1^2}$ are listed in the following table (generated using a spreadsheet program):

n_1	1	1	1	1	1	1	1	1	1	1
n_2	1	1	1	2	1	2	2	1	2	3
n_3	1	2	3	1	4	2	3	5	4	1
E	21	24	29	33	36	36	41	45	48	53

(*b*) Referring to the table, we see that the quantum numbers that correspond to degenerate energy levels are $\boxed{(1,1,4)}$ and $\boxed{(1,2,2)}$.

(*c*) For the fourth excited state, $(n_1, n_2, n_3) = (1, 1, 4)$ and the wave function is:

$$\psi(1,1,4) = \boxed{A\sin\left(\frac{\pi}{L_1}x\right)\sin\left(\frac{\pi}{2L_1}y\right)\sin\left(\frac{\pi}{L_1}z\right)}$$

20 • A particle moves in a potential well given by $U(x, y, z) = 0$ for $-L/2 < x < L/2$, $0 < y < L$, and $0 < z < L$; $U = \infty$ outside these ranges. (*a*) Write an expression for the ground-state wave function for this particle. (*b*) How do the allowed energies compare with those for a well having $U = 0$ for $0 < x < L$, rather than for $-L/2 < x < L/2$? Explain your answers.

Picture the Problem The boundary conditions in the y and z directions are the same as those in Figure 35-1. In the x direction, we'll require the $\psi = 0$ at $-L/2$ and $L/2$.

(a) The boundary conditions in the x direction are:

$$\psi\left(-\tfrac{1}{2}L\right) = \psi\left(\tfrac{1}{2}L\right) = 0$$

The general solution of the time-independent Schrödinger equation is:

$$\psi(x) = A\sin kx + B\cos kx$$

Apply the boundary conditions to obtain:

$$\psi\left(-\tfrac{1}{2}L\right) = -A\sin\left(\frac{kL}{2}\right) + B\cos\left(\frac{kL}{2}\right) = 0$$

and

$$\psi\left(\tfrac{1}{2}L\right) = A\sin\left(\frac{kL}{2}\right) + B\cos\left(\frac{kL}{2}\right) = 0$$

Eliminate the terms in B by subtracting the equations:

$$A\sin\frac{kL}{2} = 0$$

For $A \neq 0$:

$$\frac{kL}{2} = \sin^{-1} 0 = 0, \pi, 2\pi, \ldots$$

or

$$k = \frac{n_1\pi}{L}, n_1 = 0, 2, 4, \ldots$$

Eliminating the terms in A by adding the equations gives:

$$B\sin\frac{kL}{2} = 0$$

For $B \neq 0$:

$$\frac{kL}{2} = \cos^{-1} 0 = \frac{\pi}{2}, \frac{3\pi}{2}, \frac{5\pi}{2}, \ldots$$

or

$$k = \frac{n_2\pi}{L}, n_2 = 1, 3, 5, \ldots$$

Thus:

$$\psi(x,y,z) = B\cos\left(\frac{n_1\pi}{L}x\right)\sin\left(\frac{n_2\pi}{L}y\right)\sin\left(\frac{n_3\pi}{L}z\right), n_1 = 2n+1$$

and

$$\psi(x,y,z) = A\sin\left(\frac{n_1\pi}{L}x\right)\sin\left(\frac{n_2\pi}{L}y\right)\sin\left(\frac{n_3\pi}{L}z\right),\ n_1 = 2n$$

The ground-state wave function is:

$$\boxed{\psi(1,1,1) = A\cos\left(\frac{\pi}{L}x\right)\sin\left(\frac{\pi}{L}y\right)\cos\left(\frac{\pi}{L}z\right)}$$

(*b*) The allowed energies are the same as those for a well with $U = 0$ for $0 < x < L$.

21 •• A particle that is constrained to the two-dimensional region defined by $0 \le x \le L$ and $0 \le y \le L$ can move freely throughout that region. (*a*) Find the wave functions that meet these conditions and are solutions of the time-independent Schrödinger equation. (*b*) Find the energies that correspond to the wave functions in Part (*a*). (*c*) Find the quantum numbers of the two lowest states that have the same energy (that are degenerate). (*d*) Find the quantum numbers of the three states that have the same energy.

Picture the Problem (*a*) The wave functions that meet the given conditions and are solutions of the time-independent Schrödinger equation of the form $\psi = A\sin\left(\frac{n_1\pi}{L}x\right)\sin\left(\frac{n_2\pi}{L}y\right)$. (*b*) The allowed energies of the particle, as a function of the dimensions of the two-dimensional region and the quantum numbers n_1 and n_2 are given by $E_{n_1,n_2} = \frac{\hbar^2\pi^2}{2m}\left(\frac{n_1^2}{L^2} + \frac{n_2^2}{L^2}\right)$. (*c*) Degenerate energy levels correspond to sets of quantum numbers that have the same energy. These energies can be found by trial-and-error searching or by using a spreadsheet program. (*d*) We must find three different sets of quantum numbers (n_1,n_2) for which the sum of the squares are the same.

(*a*) The wave functions that satisfy the given conditions and are solutions of the time-independent Schrödinger equation are:

$$\psi(x,y) = A\sin k_1 x \sin k_2 y$$

$$= \boxed{A\sin\left(\frac{n_1\pi}{L}x\right)\sin\left(\frac{n_2\pi}{L}y\right)}$$

where n_1 and n_2 are positive integers.

(*b*) The energies that correspond to the wave functions in Part (*a*) are:

$$E_{n_1,n_2} = \boxed{\frac{h^2}{8mL^2}\left(n_1^2 + n_2^2\right)}$$

(*c*) The quantum numbers of the two lowest states that have the same energy are:

$\boxed{(1,2)}$ and $\boxed{(2,1)}$

(*d*) The energies of three lowest states that have the same energies (in units of $\frac{h^2}{8mL^2}$) are listed in the table to the right:

n_1	n_2	E_{n_1,n_2}
1	7	50
7	1	50
5	5	50

The quantum numbers for the three states are: $\boxed{(1,7)}$, $\boxed{(7,1)}$ and $\boxed{(5,5)}$

The Schrödinger Equation for Two Identical Particles

22 • Show that the two-particle wave function

$$\psi_{12} = A\sin(\pi x_1/L)\sin(2\pi x_2/L),\ 0 < x_1 < L \text{ and } 0 < x_2 < L,$$

(Equation 35-37) is a solution of

$$-\frac{\hbar^2}{2m}\frac{\partial^2\psi(x_1,x_2)}{\partial x_1^2} - \frac{\hbar^2}{2m}\frac{\partial^2\psi(x_1,x_2)}{\partial x_2^2} + U\psi(x_1,x_2) = E\psi(x_1,x_2)$$

(Equation 35-35), if $U(x_1, x_2) = 0$, and find the energy of the state represented by this wave function.

Picture the Problem We must differentiate Equation 35-37 twice and substitute these derivatives in this equation to show that it is a solution.

With $U = 0$, Equation 35-35 becomes:

$$-\frac{\hbar^2}{2m}\frac{\partial^2\psi(x_1,x_2)}{\partial x_1^2} - \frac{\hbar^2}{2m}\frac{\partial^2\psi(x_1,x_2)}{\partial x_2^2} = E\psi(x_1,x_2) \quad (1)$$

Differentiate Equation 35-7 with respect to x_1:

$$\frac{\partial\psi}{\partial x_1} = \frac{\partial}{\partial x_1}\left[A\sin\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)\right] = \frac{A\pi}{L}\cos\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)$$

Compute the second derivative with respect to x_1:

$$\frac{\partial^2\psi}{\partial x_1^2} = \frac{\partial}{\partial x_1}\left[\frac{A\pi}{L}\cos\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)\right] = -\frac{A\pi^2}{L^2}\sin\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)$$

Differentiate Equation 35-7 with respect to x_2:

$$\frac{\partial\psi}{\partial x_2}=\frac{\partial}{\partial x_2}\left[A\sin\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)\right]$$
$$=\frac{2A\pi}{L}\sin\left(\frac{\pi x_1}{L}\right)\cos\left(\frac{2\pi x_2}{L}\right)$$

Compute the second derivative with respect to x_2:

$$\frac{\partial^2\psi}{\partial x_2^2}=\frac{\partial}{\partial x_2}\left[\frac{2A\pi}{L}\sin\left(\frac{\pi x_1}{L}\right)\cos\left(\frac{2\pi x_2}{L}\right)\right]$$
$$=-\frac{4A\pi^2}{L^2}\sin\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)$$

Substitute in equation (1) to obtain:

$$-\frac{\hbar^2}{2m}\left[-\frac{A\pi^2}{L^2}\sin\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)\right]-\frac{\hbar^2}{2m}\left[-\frac{4A\pi^2}{L^2}\sin\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)\right]$$
$$=EA\sin\left(\frac{\pi x_1}{L}\right)\sin\left(\frac{2\pi x_2}{L}\right)$$

Solving for E yields:

$$E=\frac{5\hbar^2\pi^2}{2mL^2}=\frac{5h^2}{8mL^2}$$

Thus we've shown that Equation 35-37 satisfies Equation 35-35 provided $E=\dfrac{5\hbar^2\pi^2}{2mL^2}=\dfrac{5h^2}{8mL^2}$.

23 • What is the ground-state energy of ten non-interacting bosons in a one-dimensional box of length L?

Picture the Problem Because bosons have symmetric wave functions and do not obey the Pauli exclusion principle, they can occupy the same ground state.

For ten noninteracting bosons in a one-dimensional box:

$$E_{1,10\,\text{bosons}}=10E_1$$

where E_1 is the ground-state energy of a single particle in a one-dimensional box.

The ground-state energy of a single particle in a one-dimensional box of length L is given by Equation 35-14:

$$E_1=\frac{h^2}{8mL^2}$$

Substituting for E_1 and simplifying yields:

$$E_{1,10\text{ bosons}} = 10\left(\frac{h^2}{8mL^2}\right) = \boxed{\frac{5h^2}{4mL^2}}$$

24 •• What is the ground-state energy of seven identical non-interacting fermions in a one-dimensional box of length *L*? (Because the quantum number associated with spin can have two values, each spatial state can be occupied two fermions.)

Picture the Problem For fermions (particles for which the spin quantum number is ½) two particles can occupy the same spatial state.

The ground-state energy of seven fermions is:

$$E_{1,7\text{ fermions}} = E_1\left[2\left(1^2 + 2^2 + 3^2\right) + 4^2\right]$$
$$= 44E_1$$

where E_1 is the ground-state energy of a single particle in a one-dimensional box.

The ground-state energy of a single particle in a one-dimensional box of length *L* is given by Equation 35-14:

$$E_1 = \frac{h^2}{8mL^2}$$

Substituting for E_1 and simplifying yields:

$$E_{1,7\text{ fermions}} = 44\left(\frac{h^2}{8mL^2}\right) = \boxed{\frac{11h^2}{2mL^2}}$$

Orthogonality of Wave Functions

25 •• Show that the ground-state and the first excited state wave functions of the harmonic oscillator are orthogonal; that is, show that $\int \psi_0(x)\,\psi_1(x)dx = 0$.

Picture the Problem We need to show that $\int_{-\infty}^{\infty}\psi_0(x)\psi_1(x)dx = 0$, where $\psi_0(x)$ and $\psi_1(x)$ are given by Equations 35-23 and 35-25, respectively.

Equations 35-23 and 35-25 are:

$$\psi_0(x) = A_0 e^{-ax^2} \qquad 35\text{-}23$$

and

$$\psi_1(x) = A_1 x e^{-ax^2} \qquad 35\text{-}25$$

Note that $\psi_1(x)$ is antisymmetric, whereas $\psi_0(x)$ is symmetric. Because the product of an

$\psi_0(x)\psi_1(x)$ is antisymmetric

antisymmetric function and a symmetric function is antisymmetric:

Because the integral of an antisymmetric function over symmetric limits is zero:

$$\boxed{\int_{-\infty}^{\infty}\psi_0(x)\psi_1(x)dx = 0}$$

26 •• The wave function for the state $n = 2$ of the harmonic oscillator is $\psi_2(x) = A_2\left(2ax^2 - \frac{1}{2}\right)e^{-ax^2}$, where A_2 is the normalization constant and a is a positive constant. Show that the wave functions for the states $n = 1$ and $n = 2$ of the harmonic oscillator are orthogonal.

Picture the Problem We need to show that $\int_{-\infty}^{\infty}\psi_1(x)\psi_2(x)dx = 0$, where $\psi_2(x)$ is given in the problem statement and $\psi_1(x) = A_1xe^{-ax^2}$.

Note that $\psi_1(x)$ is antisymmetric, whereas $\psi_2(x)$ is symmetric. Because the product of a symmetric function and an antisymmetric function is antisymmetric, $\psi_1(x)\psi_2(x)$ is antisymmetric. Because the integral of an antisymmetric function over symmetric limits is zero:

$$\boxed{\int_{-\infty}^{\infty}\psi_1(x)\psi_2(x)dx = 0}$$

27 •• For the wave functions

$$\psi_n(x) = A\sin(n\pi x/L) \quad n = 1,\ 2,\ 3,\ k$$

corresponding to a particle in an infinite square-well potential from 0 to L, show that $\int_0^L \psi_m(x)\,\psi_n(x)dx = 0$ for all positive integers m and n, where $m \neq n$; that is, show that the wave functions are orthogonal.

Picture the Problem We need to show that $\int_0^L \sin\left(\frac{n\pi x}{L}\right)\sin\left(\frac{m\pi x}{L}\right)dx = 0.$

Use the trigonometric identity $(\sin a\alpha)(\sin b\alpha) = \frac{1}{2}\{\cos[(a-b)\alpha] - \cos[(a+b)\alpha]\}$

to rewrite the product of the two sine functions as the difference of two cosine functions:

$$\sin\left(\frac{n\pi x}{L}\right)\sin\left(\frac{m\pi x}{L}\right)=\frac{1}{2}\left\{\cos\left[(n-m)\frac{\pi x}{L}\right]-\cos\left[(n+m)\frac{\pi x}{L}\right]\right\}$$

Substitute for $\sin\left(\frac{n\pi x}{L}\right)$ and $\sin\left(\frac{m\pi x}{L}\right)$ and evaluate $\int_0^L \sin\left(\frac{n\pi x}{L}\right)\sin\left(\frac{m\pi x}{L}\right)dx$:

$$\int_0^L \frac{1}{2}\left\{\cos\left[(n-m)\frac{\pi x}{L}\right]-\cos\left[(n+m)\frac{\pi x}{L}\right]\right\}dx$$

$$=\frac{L}{\pi}\left[\frac{\sin\left[(n-m)\frac{\pi x}{L}\right]}{n-m}-\frac{\sin\left[(n+m)\frac{\pi x}{L}\right]}{n+m}\right]_0^L$$

Because n and m are integers and $n \neq m$, the sine functions vanish at the two limits $x = 0$ and $x = L$. Therefore, $\int_0^L \sin\left(\frac{n\pi x}{L}\right)\sin\left(\frac{m\pi x}{L}\right)dx = 0$ for $n \neq m$.

General Problems

28 •• Consider a particle in an infinite one-dimensional box that has a length L and is centered at the origin. (*a*) What are the values of $\psi_1(0)$ and $\psi_2(0)$? (*b*) What are the values of $\langle x\rangle$ for the $n = 1$ and $n = 2$ states? (*c*) Evaluate $\langle x^2\rangle$ for the $n = 1$ and $n = 2$ states.

Picture the Problem We can use the wave functions $\psi_1(x)$ and $\psi_2(x)$ and the definitions of $\langle x\rangle$ and $\langle x^2\rangle$ to evaluate these quantities and the wave functions at $x = 0$.

(*a*) The wave functions $\psi_1(x)$ and $\psi_2(x)$ are:

$$\psi_m=\sqrt{\frac{2}{L}}\sin\left(\frac{m\pi}{L}x\right), m = 2n$$

and

$$\psi_m=\sqrt{\frac{2}{L}}\cos\left(\frac{m\pi}{L}x\right), m = 2n+1$$

where $n = 0, 1, 2, \ldots$

Evaluate these functions at $x = 0$ to obtain:

$$\psi_1(0) = \sqrt{\frac{2}{L}}\sin\left[\frac{\pi}{L}(0)\right] = \boxed{0}$$

and

$$\psi_2(0) = \sqrt{\frac{2}{L}}\cos\left[\frac{\pi}{L}(0)\right] = \boxed{\sqrt{\frac{2}{L}}}$$

(*b*) Because $\left|\psi_m(x)\right|^2$ is an even function of x in all cases, $x\psi_m^2(x)$ is an odd function of x and:

$$\langle x\rangle = \int_{-L/2}^{L/2} x\psi_m^2(x)dx = \boxed{0}$$

(*c*) For $n = 1$:

$$\left\langle x^2\right\rangle = \frac{2}{L}\int_{-L/2}^{L/2} x^2\sin^2\frac{\pi}{L}xdx$$

From integral tables:

$$\int x^2\sin^2(ax)dx = \frac{x^3}{6} - \left(\frac{x^3}{4a} - \frac{1}{8a^3}\right)\sin(2ax) - \frac{x\cos(2ax)}{4a^2}$$

Use this integral with $a = \pi/L$ to obtain:

$$\begin{aligned}
\left\langle x^2\right\rangle &= \frac{2}{L}\int_{-L/2}^{L/2} x^2\sin^2\frac{\pi}{L}xdx \\
&= \frac{2}{L}\left[\frac{x^3}{6} - \left(\frac{x^3}{4\left(\frac{\pi}{L}\right)} - \frac{1}{8\left(\frac{\pi}{L}\right)^3}\right)\sin\left(2\left(\frac{\pi}{L}\right)x\right) - \frac{x\cos\left(2\left(\frac{\pi}{L}\right)x\right)}{4\left(\frac{\pi}{L}\right)^2}\right]_{-L/2}^{L/2} \\
&= \frac{2}{L}\left(\frac{L^3}{24} - \frac{L^3}{4\pi^2}\cos\pi\right) \\
&= \boxed{\frac{L^2}{12}\left(1 + \frac{6}{\pi^2}\right)}
\end{aligned}$$

For $n = 2$:

$$\left\langle x^2\right\rangle = \frac{2}{L}\int_{-L/2}^{L/2} x^2\sin^2\left(\frac{2\pi}{L}x\right)dx$$

Use the integral given above with $a = 2\pi/L$ to obtain:

$$\left\langle x^2\right\rangle = \frac{2}{L}\int_{-L/2}^{L/2} x^2 \sin^2\left(\frac{\pi}{L}x\right)dx$$

$$= \frac{2}{L}\left[\frac{x^3}{6} - \left(\frac{x^3}{4\left(\frac{2\pi}{L}\right)} - \frac{1}{8\left(\frac{2\pi}{L}\right)^3}\right)\sin\left(2\left(\frac{2\pi}{L}\right)x\right) - \frac{x\cos\left(2\left(\frac{2\pi}{L}\right)x\right)}{4\left(\frac{2\pi}{L}\right)^2}\right]_{-L/2}^{L/2}$$

$$= \boxed{\frac{L^2}{12}\left(1 + \frac{3}{2\pi^2}\right)}$$

Remarks: Note that for any value of *m*, $\boldsymbol{\left\langle x^2\right\rangle = \frac{L^2}{12}\left(1 + \frac{6}{m^2\pi^2}\right)}$**.**

29 •• [SSM] Eight identical non-interacting fermions are confined to an infinite two-dimensional square box of side length L. Determine the energies of the three lowest-energy states. (See Problem 22.)

Picture the Problem We can determine the energies of the state by identifying the four lowest quantum states that are occupied in the ground state and computing their combined energies. We can then find the energy difference between the ground state and the first excited state and use this information to find the energy of the excited state.

Each n, m state can accommodate only 2 particles. Therefore, in the ground state of the system of 8 fermions, the four lowest quantum states are occupied. These are:

(1,1), (1,2), (2,1) and (2,2)

Note that the states (1,2) and (2,1) are distinctly different states because the x and y directions are distinguishable.

The energies are quantized to the values given by:

$$E_{n_1,n_2} = 2\left(\frac{h^2}{8mL^2}\right)\left(n_1^2 + n_2^2\right)$$

The energy of the ground state is the sum of the energies of the four lowest quantum states:

$$\begin{aligned}E_0 &= E_{1,1} + E_{1,2} + E_{2,1} + E_{2,2}\\ &= 2\left(\frac{h^2}{8mL^2}\right)\left(1^2+1^2\right) + 2\left(\frac{h^2}{8mL^2}\right)\left(1^2+2^2\right) + 2\left(\frac{h^2}{8mL^2}\right)\left(2^2+1^2\right)\\ &\qquad + 2\left(\frac{h^2}{8mL^2}\right)\left(2^2+2^2\right)\\ &= 2\left(\frac{h^2}{8mL^2}\right)(2+5+5+8) = \frac{5h^2}{mL^2}\end{aligned}$$

The next higher state is achieved by taking one fermion from the (2, 2) state and raising it to the next higher unoccupied state. That state is the (1, 3) state. The energy difference between the ground state and this state is:

$$\begin{aligned}\Delta E &= E_{1,3} - E_{2,2}\\ &= \frac{h^2}{8mL^2}\left(1^2+3^2\right) - \frac{h^2}{8mL^2}\left(2^2+2^2\right)\\ &= \frac{h^2}{4mL^2}\end{aligned}$$

Hence, the energies of the degenerate states (1,3) and (3,1) are:

$$\begin{aligned}E_{1,3} = E_{3,1} &= E_0 + \Delta E\\ &= \frac{5h^2}{mL^2} + \frac{h^2}{4mL^2} = \frac{21h^2}{4mL^2}\end{aligned}$$

The three lowest energy levels are therefore:

$$E_0 = \boxed{\frac{5h^2}{mL^2}}$$

and two states of energy

$$E_1 = E_2 = \boxed{\frac{21h^2}{4mL^2}}$$

30 •• A particle is confined to a two-dimensional box defined by the following boundary conditions: $U(x, y) = 0$ for $-L/2 \le x \le L/2$ and $-3L/2 \le y \le 3L/2$, and $U(x, y) = \infty$ outside these ranges. (*a*) Determine the energies of the three lowest-energy states. Are any of these states degenerate? (*b*) Identify the quantum numbers of the two lowest-energy degenerate states and determine the energy of these states.

Picture the Problem (*a*) The energy levels for a two-dimensional box is given by Equation 35-34:

$$E_{n_1,n_2} = \frac{h^2}{8m}\left(\frac{n_1^2}{L_1^2} + \frac{n_2^2}{L_2^2}\right)$$

We can simplify the calculation by substituting L for L_1 and $3L$ for L_2..

(*b*) Degenerate energy states have the same energy but different quantum numbers. We can use the dependence of E_{n_1,n_2} on the quantum numbers n_1 and n_2 to identify the quantum numbers of the two lowest-energy degenerate states. Knowing their quantum numbers, we can find the energy of these states.

(*a*) The energies of the bound states are given by:

$$E_{n_1,n_2} = \frac{h^2}{8m}\left(\frac{n_1^2}{L^2} + \frac{n_2^2}{9L^2}\right) = \frac{h^2}{72mL^2}\left(9n_1^2 + n_2^2\right) \tag{1}$$

The three lowest energy states are:

$$E_{1,1} = \frac{h^2}{72mL^2}(9+1) = \boxed{\frac{5h^2}{36mL^2}}$$

$$E_{1,2} = \frac{h^2}{72mL^2}(9+4) = \boxed{\frac{13h^2}{72mL^2}}$$

and

$$E_{1,3} = \frac{h^2}{72mL^2}(9+9) = \boxed{\frac{h^2}{4mL^2}}$$

$$\boxed{\text{None of these states are degenerate.}}$$

(*b*) Let n_1, n_2 be the quantum numbers for one state and let m_1, m_2 be the quantum numbers for a second state. Then the energies of these states are given by equation (1):

$$E_{n_1,n_2} = \frac{h^2}{72mL^2}\left(9n_1^2 + n_2^2\right)$$

and

$$E_{m_1,m_2} = \frac{h^2}{72mL^2}\left(9m_1^2 + m_2^2\right)$$

Degenerate states have equal energies. Equating E_{n_1,m_1} and E_{n_2,m_2} yields:

$$9n_1^2 + n_2^2 = 9m_1^2 + m_2^2$$

We can solve this by a massive computational effort using a spreadsheet or by trial and error using educated guesses. Using educated guesses, we first look for a solution with $n_1 = 1$ and $m_1 = 2$. Substituting, this gives:

$$9 \cdot 1^2 + n_2^2 = 9 \cdot 2^2 + m_2^2$$

or

$$9 + n_2^2 = 36 + m_2^2$$

Notice that 9 and 36 are perfect squares:

$$3^2 + n_2^2 = 6^2 + m_2^2$$

We can see one solution by inspection:

$$n_2 = 6 \text{ and } m_2 = 3$$

Thus, the quantum numbers of interest are:

$$n_1 = 2, m_1 = 3, \text{and } n_2 = 1,\ m_2 = 6$$

The energy of this doubly degenerate state is:

$$E_{2,3} = \frac{h^2}{72mL^2}(36+9) = \boxed{\frac{5h^2}{8mL^2}}$$

31 ••• The classical probability distribution function for a particle in an infinite one-dimensional well of length L is $P = 1/L$. (See Example 34-5.) (*a*) Show that the classical expectation value of x^2 for a particle in an infinite one-dimensional well of length L that is centered at the origin is $L^2/12$. (*b*) Find the quantum expectation value of x^2 for the nth state of a particle in the one-dimensional box and show that it approaches the classical limit $L^2/12$ as n approaches infinity.

Picture the Problem We can use the definition of the classical expectation value (average value) to show that the classical expectation value of x^2 for a particle in a one-dimensional box of length L centered at the origin is $L^2/12$. In (*b*) we'll proceed as in (*a*) using the definition of the quantum expectation value of x^2.

(*a*) The classical expectation value of x^2 for a particle in a one-dimensional box of length L centered at the origin is given by:

$$\langle x^2 \rangle = \frac{1}{\frac{1}{2}L - \left(-\frac{1}{2}L\right)} \int_{-L/2}^{L/2} x^2 dx$$

$$= \frac{1}{L}\left[\frac{x^3}{3}\right]_{-L/2}^{L/2} = \frac{1}{L}\left(\frac{L^3}{12}\right)$$

$$= \boxed{\frac{L^2}{12}}$$

(*b*) For a particle in the *n*th state in a one-dimensional box:

$$\langle x^2\rangle = \frac{2}{L}\int_{-L/2}^{L/2} x^2\sin^2\left(\frac{n\pi}{L}x\right)dx$$

From integral tables:

$$\int x^2\sin^2(ax)dx = \frac{x^3}{6}-\left(\frac{x^3}{4a}-\frac{1}{8a^3}\right)\sin(2ax)-\frac{x\cos(2ax)}{4a^2}$$

Use this integral with $a = n\pi/L$ to obtain:

$$\begin{aligned}\langle x^2\rangle &= \frac{2}{L}\int_{-L/2}^{L/2} x^2\sin^2\left(\frac{n\pi}{L}x\right)dx\\ &= \frac{2}{L}\left[\frac{x^3}{6}-\left(\frac{x^3}{4\left(\frac{n\pi}{L}\right)}-\frac{1}{8\left(\frac{n\pi}{L}\right)^3}\right)\sin\left(2\left(\frac{n\pi}{L}\right)x\right)-\frac{x\cos\left(2\left(\frac{n\pi}{L}\right)x\right)}{4\left(\frac{n\pi}{L}\right)^2}\right]_{-L/2}^{L/2}\\ &= \boxed{\frac{2}{L}\left(\frac{L^3}{24}-\frac{L^3}{4n^2\pi^2}\cos n\pi\right)}\end{aligned}$$

In the limit $n >> 1$ we have:

$$\langle x^2\rangle = \boxed{\frac{L^2}{12}}$$

32 •• Show that Equation 35-27 and Equation 35-28 imply that the transmission coefficient for particles of energy E incident on a step barrier $U_0 < E$ is given by $T = \dfrac{4k_1k_2}{(k_1+k_2)^2} = \dfrac{4r}{(1+r)^2}$ where $r = k_2/k_1$.

Picture the Problem We can solve Equation 35-28 for T and substitute for R using Equation 35-27. Letting $r = k_2/k_1$ and simplifying will lead to the given result.

Equation 35-28 is:

$$T + R = 1 \Rightarrow T = 1 - R$$

From Equation 35-27:

$$R=\frac{(k_1-k_2)^2}{(k_1+k_2)^2}=\frac{\left(1-\frac{k_2}{k_1}\right)^2}{\left(1+\frac{k_2}{k_1}\right)^2}=\frac{(1-r)^2}{(1+r)^2}$$

where $r = k_2/k_1$

Substitute for R to obtain:

$$T=1-\frac{(1-r)^2}{(1+r)^2}=\frac{(1+r)^2-(1-r)^2}{(1+r)^2}$$

$$=\boxed{\frac{4r}{(1+r)^2}}$$

Substitute for k_2/k_1 for r and simplify to obtain:

$$T=\boxed{\frac{4k_1k_2}{(k_1+k_2)^2}}$$

33 •• (*a*) Show that for the case of a particle of energy E incident on a step barrier $U_0 < E$, the wave numbers k_1 and k_2 are related by $\frac{k_2}{k_1}=r=\sqrt{1-\frac{U_0}{E}}$. (*b*) Use this result to show that $R = (1 - r)^2/(1 + r)^2$.

Picture the Problem We can use the energies in the regions $U = 0$ and $U = U_0$ to express the ratio of the wave numbers k_1 and k_2 in these regions in terms of E and U_0 and the definition of the reflection coefficient R to show that $R=\frac{(1-r)^2}{(1+r)^2}$.

(*a*) In the region $U_0 = 0$:

$$E=\frac{\hbar^2k_1^2}{2m}\Rightarrow k_1=\sqrt{\frac{2mE}{\hbar^2}}$$

In the region $U = U_0$:

$$E-U_0=\frac{\hbar^2k_2^2}{2m}\Rightarrow k_2=\sqrt{\frac{2m(E-U_0)}{\hbar^2}}$$

Let r equal the ratio of k_2 to k_1:

$$r=\frac{k_2}{k_1}=\frac{\sqrt{\frac{2m(E-U_0)}{\hbar^2}}}{\sqrt{\frac{2mE}{\hbar^2}}}=\boxed{\sqrt{1-\frac{U_0}{E}}}$$

(*b*) The reflection coefficient R is given by:

$$R=\frac{(k_1-k_2)^2}{(k_1+k_2)^2}$$

Factor k_1 from the numerator and denominator to obtain:

$$R = \frac{\left(1 - \frac{k_2}{k_1}\right)^2}{\left(1 + \frac{k_2}{k_1}\right)^2}$$

Substitute for k_2/k_1 to obtain:

$$\boxed{R = \frac{(1-r)^2}{(1+r)^2}}$$

34 •• (*a*) Using a **spreadsheet** program or graphing calculator and the results of Problem 32 and Problem 33, graph the transmission coefficient T and reflection coefficient R as a function of incident energy E for values of E ranging from $E = U_0$ to $E = 10.0\ U_0$. (*b*) What limiting values do your graphs indicate?

Picture the Problem

(*a*) From Problem 33 we have:

$$R = \frac{(1-r)^2}{(1+r)^2}, \text{where } r = \sqrt{1 - \frac{U_0}{E}}$$

Because $E = \alpha U_0$, R can be written:

$$r = \sqrt{1 - \frac{1}{\alpha}}$$

From Problem 32 we have:

$$T = \frac{4r}{(1+r)^2}$$

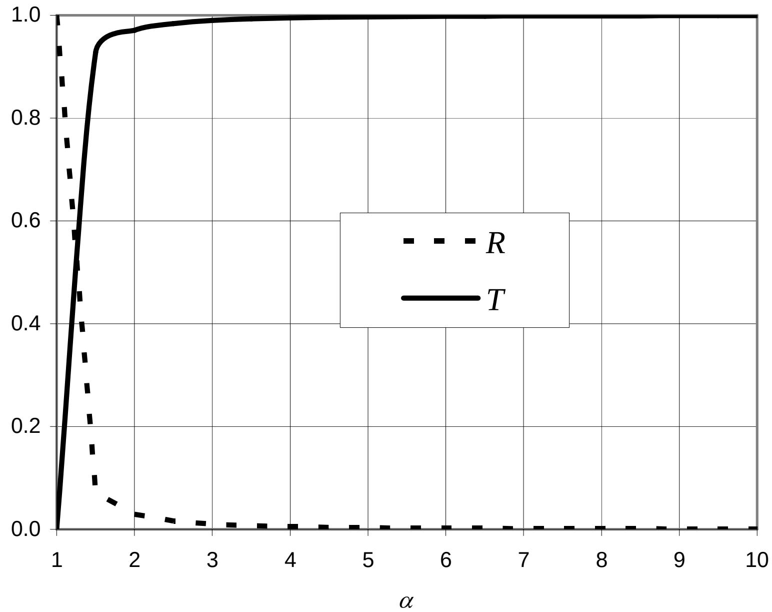
A spreadsheet program to plot R and T as functions of α is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A2	1.0	α
B2	SQRT(1–1/A2)	$\sqrt{1-\frac{1}{\alpha}}$
C2	(1–B2)^2/(1+B2)^2	$\frac{(1-r)^2}{(1+r)^2}$
D2	4*B2//(1+B2)^2	$\frac{4r}{(1+r)^2}$

	A	B	C	D
1	α	r	R	T
2	1.0	0.000	1.000	0.000
3	1.5	0.577	0.072	0.928
4	2.0	0.707	0.029	0.971

5	2.5	0.775	0.016	0.984
16	8.0	0.935	0.001	0.999
17	8.5	0.939	0.001	0.999
18	9.0	0.943	0.001	0.999
19	9.5	0.946	0.001	0.999
20	10.0	0.949	0.001	0.999

The following graph of R and T as functions of α was plotted using the data in the table:



(b) Referring to the graph, note that, as $\alpha \to \infty$. $T \to 1$ and $R \to 0$. The graph also shows that, as $\alpha \to 1$, $T \to 0$ and $R \to 1$.

35 ••• The wave function for the state $n = 2$ of the harmonic oscillator is $\psi_2(x) = A_2\left(2ax^2 - \frac{1}{2}\right)e^{-ax^2}$, where $a = \frac{1}{2}m\omega_0/h$. Determine the normalization constant A_2.

Picture the Problem We can find the normalization constant by requiring that

$$A_2^2 \int_{-\infty}^{\infty} \left(2ax^2 - \tfrac{1}{2}\right)^2 e^{-2ax^2} dx = 2A_2^2 \int_0^{\infty} \left(2ax^2 - \tfrac{1}{2}\right)^2 e^{-2ax^2} dx = 1.$$

Expand the integrand to obtain:

$$\left(2ax^2 - \tfrac{1}{2}\right)^2 e^{-2ax^2} = \left(4a^2x^4 - 2ax^2 + \tfrac{1}{4}\right)e^{-2ax^2} = 4a^2x^4e^{-2ax^2} - 2ax^2e^{-2ax^2} + \tfrac{1}{4}e^{-2ax^2}$$

Substitute in the integral expression to obtain:

$$2A_2^2\int_0^\infty\left(4a^2x^4e^{-2ax^2}-2ax^2e^{-2ax^2}+\tfrac{1}{4}e^{-2ax^2}\right)dx=1$$

or

$$8a^2A_2^2\int_0^\infty x^4e^{-2ax^2}dx-4aA_2^2\int_0^\infty x^2e^{-2ax^2}dx+\tfrac{1}{2}A_2^2\int_0^\infty e^{-2ax^2}dx=1 \qquad (1)$$

Use the definite integral

$$\int_0^\infty e^{-bx^2}dx=\frac{1}{2}\sqrt{\frac{\pi}{b}} \text{ and } \int_0^\infty x^{2n}e^{-bx^2}dx=\frac{1\cdot3\cdot5\cdots(2n-1)}{2^{n+1}b^n}\sqrt{\frac{\pi}{b}}\quad, n\geq 1,$$

(see Table D-5) to integrate equation (1) term by term:

$$8a^2A_2^2\left[\frac{3}{2^3(2a)^2}\sqrt{\frac{\pi}{2a}}\right]-4aA_2^2\left[\frac{1}{2^2(2a)}\sqrt{\frac{\pi}{2a}}\right]+\tfrac{1}{2}A_2^2\left[\frac{1}{2}\sqrt{\frac{\pi}{2a}}\right]=1$$

Simplify to obtain:

$$A_2^2\left[\frac{3}{4}\sqrt{\frac{\pi}{2a}}-\frac{1}{2}\sqrt{\frac{\pi}{2a}}+\frac{1}{4}\sqrt{\frac{\pi}{2a}}\right]=1$$

or

$$A_2^2\left[\frac{1}{2}\sqrt{\frac{\pi}{2a}}\right]=1\Rightarrow A_2=\sqrt{2\sqrt{\frac{2a}{\pi}}}$$

Because $a=\dfrac{m\omega_0}{2\hbar}=\dfrac{m\omega_0\pi}{h}$

$$A_2=\boxed{\sqrt[4]{\frac{8m\omega_0}{h}}}$$

36 ••• Consider the time-independent, one-dimensional Schrödinger equation when the potential function is symmetric about the origin, that is, when $U(x)$ is even.[1] (*a*) Show that if $\psi(x)$ is a solution of the Schrödinger equation and has energy E, then $\psi(-x)$ is also a solution that has the same energy E. Furthermore, $\psi(x)$ and $\psi(-x)$ can differ by only a multiplicative constant. (*b*) Write $\psi(x)=C\psi(-x)$, and show that $C=\pm1$. Note that $C=+1$ means that $\psi(x)$ is an even function of x, and $C=-1$ means that $\psi(x)$ is an odd function of x.

[1] A function $f(x)$ is even if $f(x)=f(-x)$ for all x, and a function $f(x)$ is odd if $f(x)=-f(-x)$ for all x.

Picture the Problem
(a) Let $x = -x$. The second derivative is an even operator, that is, $d^2\psi(-x)/d(-x)^2 = d^2\psi(x)/dx^2$. Therefore, if $U(-x) = U(x)$, the Schrödinger equation for $\psi(-x) = \psi(x)$ and must give the same values for the energy E. If $\psi(-x)$ differs from $\psi(x)$, the ratio $\psi(-x)/\psi(x)$ cannot be a function of x and must be a constant. Hence, $\psi(x) = C\psi(-x)$.

(b) The previous result means that replacing the argument of the wave function by its negative is equivalent to multiplication by C. Thus, if we replace $C\psi(-x)$ argument by its negative, that is, by x, we must multiply by C again. Thus, $\psi(x) = C^2\psi(x)$, $C^2 = 1$, and $C = \pm 1$.

37 ••• [SSM] In this problem, you will derive the ground-state energy of the harmonic oscillator using the precise form of the uncertainty principle, $\Delta x\Delta p_x \geq h/2$, where Δx and Δp_x are defined to be the standard deviations $(\Delta x)^2 = \left\langle\left(x - \langle x\rangle\right)^2\right\rangle$ and $(\Delta p_x)^2 = \left\langle\left(p_x - \langle p_x\rangle\right)^2\right\rangle$. Proceed as follows:
1. Write the total classical energy in terms of the position x and momentum p_x using $U(x) = \frac{1}{2}m\omega_0^2x^2$ and $K = \frac{1}{2}p_x^2/m$.
2. Show that $(\Delta x)^2 = \left\langle\left(x - \langle x\rangle\right)^2\right\rangle = \langle x^2\rangle - \langle x\rangle^2$ and $(\Delta p_x)^2 = \left\langle\left(p_x - \langle p_x\rangle\right)^2\right\rangle = \langle p_x^2\rangle - \langle p_x\rangle^2$. (Hint: See Equations 17-34a and 17-34b.)
3. Use the symmetry of the potential energy function to argue that $\langle x\rangle$ and $\langle p_x\rangle$ must be zero, so that $(\Delta x)^2 = \langle x^2\rangle$ and $(\Delta p_x)^2 = \langle p_x^2\rangle$.
4. Assume that $\Delta x\Delta p_x = h/2$ to eliminate $\langle p_x^2\rangle$ from the average energy $\langle E\rangle = \left\langle\frac{1}{2}p_x^2/m + \frac{1}{2}m\omega_0^2x^2\right\rangle = \frac{1}{2}\langle p_x^2\rangle/m + \frac{1}{2}m\omega_0^2\langle x^2\rangle$ and write $\langle E\rangle$ as $\langle E\rangle = h^2/(8mZ) + \frac{1}{2}m\omega_0^2 Z$, where $Z = \langle x^2\rangle$.
5. Set $d\langle E\rangle/dZ = 0$ to find the value of Z for which $\langle E\rangle$ is a minimum.
6. Show that the minimum energy is given by $\langle E\rangle_{\text{min}} = +\frac{1}{2}h\omega_0$.

Picture the Problem We can follow the step-by-step procedure outlined in the problem statement to show that $\langle E\rangle_{\text{min}} = +\frac{1}{2}h\omega_0$.

1. The total classical energy is:

$$E = K + U(x) = \frac{p_x^2}{2m} + \frac{1}{2}m\omega_0^2x^2$$

Hence the average classical energy is given by:

$$\langle E\rangle = \left\langle \frac{p_x^2}{2m} + \tfrac{1}{2}m\omega_0^2 x^2 \right\rangle \qquad (1)$$

2. Express the standard deviation of Δp_x:

$$\begin{aligned}(\Delta p_x)^2 &= \left\langle \left(p_x - \langle p_x\rangle\right)^2 \right\rangle \\ &= \left\langle p_x^2 - 2p_x\langle p_x\rangle + \langle p_x\rangle^2 \right\rangle \\ &= \left\langle p_x^2\right\rangle - 2\langle p_x\rangle\langle p_x\rangle + \langle p_x\rangle^2 \\ &= \left\langle p_x^2\right\rangle - \langle p_x\rangle^2\end{aligned}$$

Proceeding similarly for the standard deviation of Δx gives:

$$(\Delta x)^2 = \left\langle x^2\right\rangle - \langle x\rangle^2$$

3. From the symmetry of the potential energy function we can conclude that $\langle x\rangle$ and $\langle p_x\rangle$ must be zero. Hence:

$$(\Delta x)^2 = \left\langle x^2\right\rangle$$

and

$$(\Delta p_x)^2 = \left\langle p_x^2\right\rangle$$

4. Rewrite equation (1) in terms of $(\Delta p_x)^2$ to obtain:

$$\begin{aligned}\langle E\rangle &= \frac{\left\langle p_x^2\right\rangle}{2m} + \tfrac{1}{2}m\omega_0^2\left\langle x^2\right\rangle \\ &= \frac{(\Delta p_x)^2}{2m} + \tfrac{1}{2}m\omega_0^2\left\langle x^2\right\rangle\end{aligned}$$

Using the uncertainty principle ($\Delta x\,\Delta p_x = h/2$) to eliminate $\left\langle p_x^2\right\rangle$ gives:

$$\begin{aligned}\langle E\rangle &= \frac{\left(\dfrac{h}{2\Delta x}\right)^2}{2m} + \tfrac{1}{2}m\omega_0^2\left\langle x^2\right\rangle \\ &= \frac{h^2}{8m(\Delta x)^2} + \tfrac{1}{2}m\omega_0^2\left\langle x^2\right\rangle \\ &= \frac{h^2}{8m\left\langle x^2\right\rangle} + \tfrac{1}{2}m\omega_0^2\left\langle x^2\right\rangle\end{aligned}$$

Letting $Z = \left\langle x^2\right\rangle$ yields:

$$\langle E\rangle = \frac{h^2}{8mZ} + \tfrac{1}{2}m\omega_0^2 Z$$

5. Differentiate $\langle E\rangle$ with respect to Z and set this derivative equal to zero:

$$\frac{d\langle E\rangle}{dZ}=\frac{d}{dZ}\left[\frac{h^2}{8mZ}+\tfrac{1}{2}m\omega_0^2 Z\right]$$
$$=-\frac{h^2}{8mZ^2}+\tfrac{1}{2}m\omega_0^2$$
$$=0 \text{ for extrema}$$

Solve for Z to find the value of Z that minimizes $\langle E\rangle$ (see the remark below):

$$Z=\frac{h}{2m\omega_0}$$

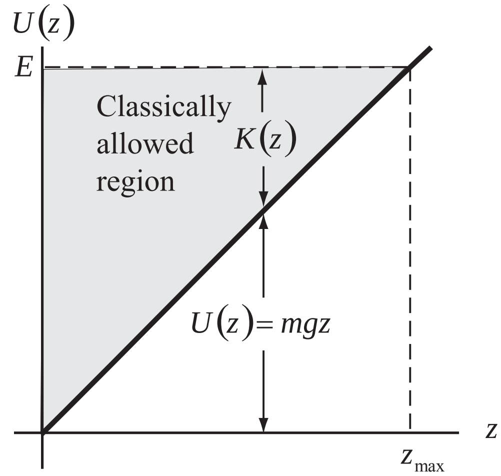
6. Evaluating $\langle E\rangle$ when $Z=\dfrac{h}{2m\omega_0}$ gives:

$$\langle E\rangle_{\text{min}}=\frac{h^2}{8m}\left(\frac{2m\omega_0}{h}\right)+\tfrac{1}{2}m\omega_0^2\left(\frac{h}{2m\omega_0}\right)$$
$$=\boxed{+\tfrac{1}{2}h\omega_0}$$

Remarks: All we've shown is that $Z = h/(2m\omega_0)$ is an extreme value, i.e., either a *maximum* or a *minimum*. To show that $Z = \hbar/(2m\omega_0)$ minimizes <E> we must either 1) show that the second derivative of <E> with respect to Z evaluated at $Z = h/(2m\omega_0)$ is positive, or 2) confirm that the graph of <E> as a function of Z opens upward at $Z = h/(2m\omega_0)$.

38 ••• A particle that has mass m and is near Earth's surface, at which $z = 0$, can be described by the potential energy function $U = mgz$ in the region $z > 0$, and by $U = \infty$ in the region $z < 0$. Sketch a graph of $U(z)$ versus z. For some positive value of total energy E, indicate the classically allowed region on the graph and plot the classical kinetic energy versus z on the graph. The Schrödinger equation for this problem is quite difficult to solve. Using arguments similar to those in Section 35-2 about the concavity of the wave function as given by the Schrödinger equation, sketch the shape of the wave function for the ground state and for the first two excited states.

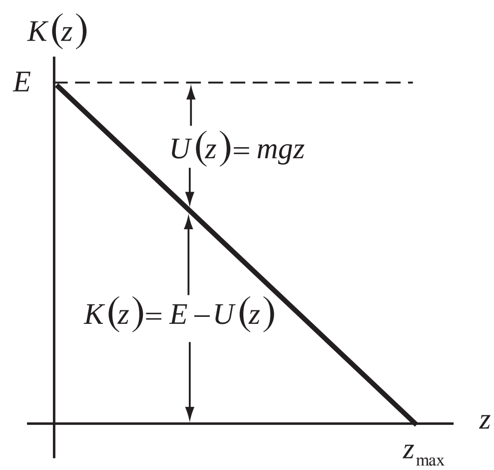
Picture the Problem
The classically allowed region is for $E \ge U(z)$. In the figure to the right, this region extends from $z = 0$ to $z = z_{max}$.



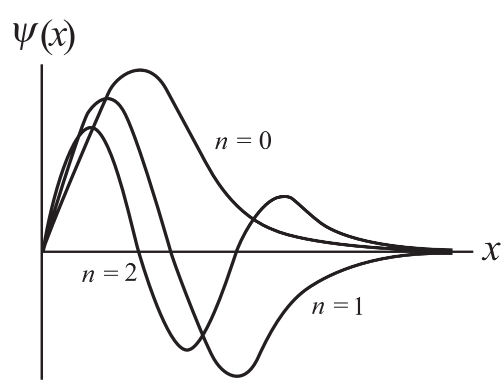
The total energy of the particle is the sum of its kinetic and potential energies:

$$E = K(z) + U(z) \Rightarrow K(z) = E - U(z)$$

A graph of the classical kinetic energy versus z is shown to the right:



A sketch of the wave functions for the lowest three energy states is shown to the right:



Chapter 36
Atoms

Conceptual Problems

1 • For the hydrogen atom, as n increases, does the spacing of adjacent energy levels on an energy-level diagram increase or decrease?

Determine the Concept Examination of Figure 35-4 indicates that as n increases, the spacing of adjacent energy levels decreases**.**

2 • The energy of the ground state of doubly ionized lithium (Z = 3) is _____, where E_0 = 13.6 eV. (a) $-9E_0$, (b) $-3E_0$, (c) $-E_0/3$, (d) $-E_0/9$.

Picture the Problem The energy of an atom of atomic number Z, with exactly one electron in its nth energy state is given by $E_n = -Z^2\dfrac{E_0}{n^2}, n = 1, 2, 3, \ldots$.

Express the energy of an atom of atomic number Z, with exactly one electron, in its nth energy state:

$$E_n = -Z^2\frac{E_0}{n^2}, n = 1, 2, 3, \ldots$$

where E_0 is the atom's ground state energy.

For lithium (Z = 3) in its first excited state (n = 1) this expression becomes:

$$E_2 = -(3)^2\frac{E_0}{1^2} = -9E_0$$

and $\boxed{(a)}$ is correct.

3 • Bohr's quantum condition on electron orbits requires (a) that the orbital angular momentum of the electron about the hydrogen nucleus equals $n\hbar$, where n is an integer, (b) that no more than one electron occupy a given state, (c) that the electrons spiral into the nucleus while radiating electromagnetic waves, (d) that the energies of an electron in a hydrogen atom be equal to nE_0, where E_0 is a constant and n is an integer, (e) none of the above.

Determine the Concept Bohr's postulates are 1) the electron in the hydrogen atom can move only in certain non-radiating, circular orbits called *stationary states*, 2) if E_i and E_f are the initial and final energies of the atom, the frequency f of the emitted radiation during a transition is given by $f = [E_i - E_f]/h$, and 3) the angular momentum of a circular orbit is constrained by $mvr = n\hbar$. $\boxed{(a)}$ is correct.

4 •• According to the Bohr model, if an electron moves to a larger orbit, does the electron's total energy increase or decrease? Does the electron's kinetic energy increase or decrease?

Picture the Problem We can express the kinetic energy of the orbiting electron as well as its total energy as functions of its radius r.

Express the total energy of an orbiting electron:

$$E = K + U$$

Express the orbital kinetic energy of an electron:

$$K = \frac{kZe^2}{2r} \qquad (1)$$

Express the potential energy of an orbiting electron:

$$U = -\frac{kZe^2}{r}$$

Thus, as r increases, E becomes less negative and therefore increases.

Examination of the expression for K makes it clear that if r increases, K decreases.

5 • According to the Bohr model, the kinetic energy of the electron in the ground state of hydrogen is E_0, where $E_0 = 13.6$ eV. The kinetic energy of the electron in the state $n = 2$ is (*a*) $4E_0$, (*b*) $2E_0$, (*c*) $E_0/2$, (*d*) $E_0/4$.

Picture the Problem We can relate the kinetic energy of the electron in the $n = 2$ state to its total energy using $E_2 = K_2 + U_2$.

Express the total energy of the hydrogen atom in its $n = 2$ state:

$$E_2 = K_2 + U_2 = K_2 - 2K_2 = -K_2$$

or

$$K_2 = -E_2$$

Express the energy of hydrogen in its nth energy state:

$$E_n = -Z^2\frac{E_0}{n^2} = -(1)^2\frac{E_0}{n^2} = -\frac{E_0}{n^2}$$

where E_0 is hydrogen's ground state energy and $Z = 1$.

Substitute to obtain:

$$K_n = \frac{E_0}{n^2} \text{ and } K_2 = \frac{E_0}{2^2} = \frac{E_0}{4}$$

$\boxed{(d)}$ is correct.

6 • According to the Bohr model, the radius of the $n = 1$ orbit in the hydrogen atom is $a_0 = 0.053$ nm. What is the radius of the $n = 5$ orbit? (*a*) $25a_0$, (*b*) $5a_0$, (*c*) a_0, (*d*) $a_0/5$, (*e*) $a_0/25$.

Picture the Problem The orbital radius r depends on the $n = 1$ orbital radius a_0, the atomic number Z, and the orbital quantum number n according to $r = n^2a_0/Z$.

The radius of the $n = 5$ orbit is:

$$r_5 = 5^2\left(\frac{a_0}{1}\right) = 25a_0$$

because $Z = 1$ for hydrogen.

$\boxed{(a)}$ is correct.

7 • **[SSM]** For the principal quantum number $n = 4$, how many different values can the orbital quantum number ℓ have? (*a*) 4, (*b*) 3, (*c*) 7, (*d*) 16, (*e*) 25

Determine the Concept We can find the possible values of ℓ by using the constraints on the quantum numbers *n* and ℓ.

The allowed values for the orbital quantum number ℓ for $n = 1, 2, 3$, and 4 are summarized in table shown to the right:

n	ℓ
1	0
2	0, 1
3	0, 1, 2
4	0, 1, 2, 3

From the table it is clear that ℓ can have 4 values. $\boxed{(a)}$ is correct.

8 • For the principal quantum number $n = 4$, how many different combinations of ℓ and m_ℓ can occur? (*a*) 4, (*b*) 3, (*c*) 7, (*d*) 16, (*e*) 25

Picture the Problem We can find the number of different values m_ℓ can have by enumerating the possibilities when the principal quantum number $n = 4$.

The allowed values for the orbital quantum number ℓ and the magnetic quantum number m_ℓ for $n = 4$ are summarized to the right:

$\ell = 0, 1, 2, 3$

and

$m_\ell = -3, -2, -1, 0, 1, 2, 3$

When $\ell = 0$, $m_\ell = 0 \Rightarrow$ 1 combination: (0,0)

When $\ell = 1$, $m_\ell = -1,0,1 \Rightarrow$ 3 combinations: (1, −1), (1,0) and (1,1)

When $\ell = 2$ $m_\ell = -2, -1,0,1,2 \Rightarrow$ 5 combinations: (2, −2), (2,−1), (2,0), (2,1) and (2,2)

When $\ell = 3$ $m_\ell = -3,-2, -1,0,1,2,3 \Rightarrow$ 7 combinations: (3, −3), (3,−2), (3, −1), (3,0), (3,1), (3,2) and (3,3)

From this enumeration we can see that 16 combinations of ℓ and m_ℓ can occur.

$\boxed{(d)}$ is correct.

Remarks: For n = 4 the orbital quantum number ℓ can be 0, 1, 2, or 3, and for each value ℓ there are 2*ℓ + 1 values of the magnetic quantum number. Thus the total number of combinations are (2*3 + 1) + (2*2 + 1) + (2*1 + 1) + (2*0 + 1) = 7 + 5 + 3 + 1 = 16.

9 •• **[SSM]** Why is the energy of the 3s state considerably lower than the energy of the 3p state for sodium, whereas in hydrogen 3s and 3p states have essentially the same energy?

Determine the Concept The s state, with $\ell = 0$, is a ″penetrating″ state in which the probability density near the nucleus is significant. Consequently, the 3s electron in sodium is in a region of low potential energy for a significant portion of the time. In the state $\ell = 1$, the probability density at the nucleus is zero, so the 3p electron of sodium is shielded from the nuclear charge by the 1s electrons. In hydrogen, the 3s and 3p electrons experience the same nuclear potential.

10 • The d state of an electron configuration corresponds to (*a*) $n = 2$, (*b*) $\ell = 3$, (*c*) $\ell = 2$, (*d*) $n = 3$, (*e*) $\ell = 0$.

Picture the Problem We can visualize the relationship between the quantum number ℓ and the electronic configuration as shown in the table below.

	s	p	d	f	g	h
ℓ value	0	1	2	3	4	5

Because the d state corresponds to $\ell = 2$, $\boxed{(c)}$ is correct.

11 •• Why are three quantum numbers inadequate to describe the states of the electrons in atoms that have more than one electron?

Determine the Concept In conformity with the exclusion principle, the total number of electrons that can be accommodated in states of quantum number n is n^2 (see Problem 48). The fact that closed shells correspond to $2n^2$ electrons indicates that there is another quantum number that can have two possible values.

12 •• Group the following six atoms—potassium, calcium, titanium, chromium, manganese, and copper—according to their ground state electron configurations for the $n = 4$ shell.

Picture the Problem We can group these atoms by using Table 36-1 to look for a common outer electronic configuration in the ground states.

The following atoms have an outer $4s^2$ configuration in the ground state: $\boxed{\text{titanium, manganese, and calcium}}$

The following atoms have an outer 4s configuration in the ground state: $\boxed{\text{potassium, chromium, and copper.}}$

Remarks: It is to be expected that atoms of the first group will have similar properties, and, likewise, that atoms of the second group will have similar properties.

13 • What element has the electron configuration (*a*) $1s^22s^22p^63s^23p^3$ and (*b*) $1s^22s^22p^63s^23p^63d^54s^1$?

Picture the Problem We can use the fact that the sum of the exponents in the electronic configuration representation is the atomic number to identify these two elements.

(*a*) Adding the exponents yields a sum of 15. Because this sum is the atomic number, *Z*, the element must be $\boxed{\text{phosphorus.}}$

(*b*) Adding the exponents yields a sum of 24. Because this sum is the atomic number, *Z*, the element must be $\boxed{\text{chromium.}}$

Remarks: Checking the electronic configurations in Table 36-1 further confirms these conclusions.

14 • For the principal quantum number $n = 3$, what are the possible combinations of the quantum numbers ℓ and m_ℓ?

Picture the Problem We can apply the constraints on the quantum numbers ℓ and m_ℓ to find the possible values for each when $n = 3$.

Express the constraints on the quantum numbers n, ℓ, and m_ℓ:

$$n = 1, 2, 3, \ldots,$$
$$\ell = 0, 1, 2, \ldots, n-1,$$
and
$$m_\ell = -\ell, -\ell+1, \ldots, \ell$$

For $n = 3$, the constraints on ℓ limit it to the values:

$$\ell = 0, 1, \text{and } 2$$

m_ℓ can take on the values:

$$m_\ell = -2, -1, 0, 1, 2$$

When $\ell = 0$, $m_\ell = 0 \Rightarrow$ 1 combination: (0,0)

When $\ell = 1$, $m_\ell = -1,0,1 \Rightarrow$ 3 combinations: (1, −1), (1,0) and (1,1)

When $\ell = 2$ $m_\ell = -2, -1,0,1,2 \Rightarrow$ 5 combinations: (2, −2), (2,−1), (2,0), (2,1) and (2,2)

The possible combinations of the quantum numbers ℓ and m_ℓ are (0,0), (1, −1), (1,0), (1,1), (2, −2), (2,−1), (2,0), (2,1) and (2,2).

15 • An electron in the *L* shell means that the electron is represented by (*a*) $\ell = 0$, (*b*) $\ell = 1$, (*c*) $n = 1$, (*d*) $n = 2$, or (*e*) $m_\ell = 2$.

Determine the Concept The correspondence between the letter designations K, L, M, N, O, and P for the shells and the principal quantum number *n* is summarized in the table below.

Shell designation	K	L	M	N	O	P	Q
n	1	2	3	4	5	6	7
ℓ	0	0	0	0	0	0	0
		1	1	1	1	1	1
			2	2	2	2	2
				3	3	3	3
					4	4	4
						5	5
							6

While $n = 2$ for the L shell, ℓ can be either 0 or 1. $\boxed{(d)}$ is correct.

16 •• The Bohr model and the quantum-mechanical model of the hydrogen atom give the same results for the energy levels. Discuss the advantages and disadvantages of each model.

Picture the Problem The strengths and weaknesses of each model are summarized in the following table.

	Bohr Model	Quantum-Mechanical Model
Ease of application	Easy	Difficult
Prediction of stationary state energies	Correct predictions	Correct predictions
Prediction of angular momenta	Predicts incorrect results	Predicts correct results
Spatial distribution of electrons	Predicts incorrect results	Predicts correct probabilistic distribution

17 •• The Sommerfeld–Hosser displacement theorem states that the optical spectrum of any atom is very similar to the spectrum of the singly charged positive ion of the element immediately following it in the periodic table. Discuss why this theorem is accurate.

Determine the Concept The optical spectrum of any atom is due to the configuration of its outer-shell electrons. Ionizing the next atom in the periodic table gives you an ion with the same number of outer-shell electrons, and almost the same nuclear charge. Hence, the spectra should be very similar.

18 • Using the triplet of numbers (n, ℓ, m_ℓ) to represent an electron that has the principal quantum number n, orbital quantum number ℓ, and magnetic quantum number m_ℓ, which of the following transitions is allowed?
(*a*) $(5, 2, 2) \rightarrow (3, 1, -2)$, (*b*) $(2, 1, 0) \rightarrow (3, 0, 0)$, (*c*) $(4, 3, -2) \rightarrow (3, 2, -1)$,
(*d*) $(1, 0, 0) \rightarrow (2, 1, -1)$, (*e*) $(2, 1, 0) \rightarrow (3, 1, 0)$

Determine the Concept An allowed transition must satisfy the selection rules $\Delta m_\ell = 0$ or ± 1 and $\Delta\ell = \pm 1$.

(*a*) $\Delta\ell = -1$ and $\Delta m_\ell = -4 \Rightarrow$ $\boxed{\text{not allowed}}$

(*b*) $\Delta\ell = -1$ and $\Delta m_\ell = 0 \Rightarrow$ $\boxed{\text{allowed}}$

(*c*) $\Delta\ell = -1$ and $\Delta m_\ell = +1 \Rightarrow$ $\boxed{\text{allowed}}$

(*d*) $\Delta\ell = +1$ and $\Delta m_\ell = -1 \Rightarrow$ $\boxed{\text{allowed}}$

(*e*) $\Delta\ell = 0$ and $\Delta m_\ell = 0 \Rightarrow$: $\boxed{\text{not allowed}}$

19 •• [SSM] The Ritz combination principle states that for any atom, one can find different spectral lines λ_1, λ_2, λ_3, and λ_4, so that $1/\lambda_1 + 1/\lambda_2 = 1/\lambda_3 + 1/\lambda_4$. Show why this is true using an energy-level diagram.

Determine the Concept The Ritz combination principle is due to the quantization of energy levels in the atom. We can use the relationship between the wavelength of the emitted photon and the difference in energy levels within the atom that results in the emission of the photon to express each of the wavelengths and then the sum of the reciprocals of the first and second wavelengths and the sum of the reciprocals of the third and fourth wavelengths.

Express the wavelengths of the spectral lines λ_1, λ_2, λ_3, and λ_4 in terms of the corresponding energy transitions:

$$\lambda_1 = \frac{hc}{E_3 - E_2},\ \lambda_2 = \frac{hc}{E_2 - E_0}$$

$$\lambda_3 = \frac{hc}{E_3 - E_1} \text{ and } \lambda_4 = \frac{hc}{E_1 - E_0}$$

Add the reciprocals of λ_1 and λ_2 to obtain:

$$\frac{1}{\lambda_1} + \frac{1}{\lambda_2} = \frac{E_3 - E_2}{hc} + \frac{E_2 - E_0}{hc} = \frac{E_3 - E_0}{hc} \quad (1)$$

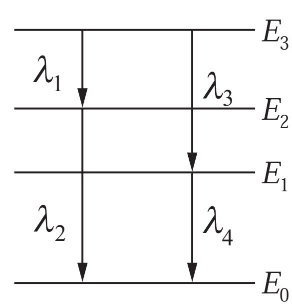
Add the reciprocals of λ_3 and λ_4 to obtain:

$$\frac{1}{\lambda_3} + \frac{1}{\lambda_4} = \frac{E_3 - E_1}{hc} + \frac{E_1 - E_0}{hc} = \frac{E_3 - E_0}{hc} \quad (2)$$

Because the right-hand sides of equations (1) and (2) are equal:

$$\boxed{\frac{1}{\lambda_1} + \frac{1}{\lambda_2} = \frac{1}{\lambda_3} + \frac{1}{\lambda_4}}$$

One possible set of energy levels is shown to the right:



Estimation and Approximation

20 •• (*a*) We can define a thermal de Broglie wavelength λ_T for an atom in a gas at temperature T as being the de Broglie wavelength for an atom moving at the rms speed appropriate to that temperature. (The average kinetic energy of an

atom is equal to kT, where k is the Boltzman constant. Use this value to calculate the rms speed of the atoms.) Show that $\lambda_T = \sqrt{h^2/3mkT}$, where m is the mass of the atom. (*b*) Cooled atoms can form a Bose *condensate* (a new state of matter) when their thermal de Broglie wavelength becomes larger than the average interatomic spacing. From this criterion, estimate the temperature needed to create a Bose condensate in a gas of ^{85}Rb atoms whose number density is 10^{12} atoms/cm^3.

Picture the Problem We can use the relationship between the kinetic energy of an atom and its momentum, together with the de Broglie equation, to derive the expression for the thermal de Broglie wavelength. In Part (*b*), we can use the definition of the number density of atoms and the result from Part (*a*), with the interatomic spacing set equal to the thermal de Broglie wavelength, to estimate the temperature needed to create a Bose condensate.

(*a*) Express the kinetic energy of an atom in terms of its momentum:

$$K = \frac{p^2}{2m}$$

Use the de Broglie relationship to express the atom's momentum in terms of its de Broglie wavelength:

$$p = \frac{h}{\lambda_T}$$

where λ_T is the thermal de Broglie wavelength.

Substituting for p gives:

$$K = \frac{h^2}{2m\lambda_T^2}$$

The kinetic energy of an atom is also a function of its temperature T:

$$K = \frac{3}{2}kT$$

Equate these expressions for K to obtain:

$$\frac{3}{2}kT = \frac{h^2}{2m\lambda_T^2} \Rightarrow \lambda_T = \boxed{\sqrt{\frac{h^2}{3mkT}}}$$

(*b*) The number density of atoms ρ is given by:

$$\rho = \frac{N}{V}$$

where N is the number of atoms and V is the volume they occupy.

Assume that each atom is arrayed on a cubic lattice of spacing d to obtain:

$V = Nd^3$ and $\rho = \dfrac{N}{Nd^3} = \dfrac{1}{d^3}$

Solving for d yields:

$$d = \rho^{-1/3}$$

Setting $d = \lambda_T$ gives:

$$\rho^{-1/3} = \sqrt{\frac{h^2}{3mkT}} \Rightarrow T = \frac{h^2 \rho^{2/3}}{3mk}$$

Substitute numerical values and evaluate T:

$$T = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})^2 \left(10^{12}\ \frac{\text{atoms}}{\text{cm}^3} \times \frac{10^6\ \text{cm}^3}{\text{m}^3}\right)^{2/3}}{3(85\,\text{u})\left(1.661\times10^{-27}\ \frac{\text{kg}}{\text{u}}\right)\left(1.381\times10^{-23}\ \frac{\text{J}}{\text{K}}\right)} = \boxed{75\,\text{nK}}$$

21 •• In laser cooling and trapping, a beam of atoms traveling in one direction are slowed by interaction with an intense laser beam in the opposite direction. The photons scatter off the atoms by resonance absorption, a process by which the incident photon is absorbed by the atom, and a short time later a photon of equal energy is emitted in a random direction. The net result of a single such scattering event is a transfer of momentum to the atom in a direction opposite to the motion of the atom, followed by a second transfer of momentum to the atom in a random direction. Thus, during photon absorption the atom loses speed, but during photon emission the change in speed of the atom is, on average, zero (because the directions of the emitted photons are random). An analogy often made to this process is that of slowing down a bowling ball by bouncing ping-pong balls off of it. (*a*) Given that the typical photon energy used in these experiments is about 1 eV, and that the typical kinetic energy of an atom in the beam is the typical kinetic energy of the atoms in a gas that has a temperature of about 500 K (a typical temperature for an oven that produces an atomic beam), estimate the number of photon-atom collisions that are required to bring an atom to rest. (The average kinetic energy of an atom is equal to $\frac{3}{2}kT$, where k is the Boltzmann constant and T is the temperature. Use this to estimate the speed of the atoms.) (*b*) Compare the Part (*a*) result with the number of ping-pong ball–bowling ball collisions that are required to bring the bowling ball to rest. Assume the typical speed of the incident ping-pong balls are all equal to the initial speed of the bowling ball.) (*c*) ^{85}Rb is a type of atom often used during cooling experiments. The wavelength of the light resonant with the cooling transition of these atoms is $\lambda = 780.24$ nm. Estimate the number of photons needed to slow down an ^{85}Rb atom from a typical thermal velocity of 300 m/s to a stop.

Picture the Problem The number of photons needed to stop a ^{85}Rb atom traveling at 300 m/s is the ratio of its momentum to that of a typical photon. In Part (*b*), assume the mass of a bowling ball to be 6.0 kg and the mass of a ping pong ball to be 4.0 g.

(*a*) The number N of photon-atom collisions needed to bring an atom to rest is the ratio of the change in the momentum of the atom as it stops to the momentum brought to the collision by each photon:

$$N = \frac{\Delta p_{\text{atom}}}{p_{\text{photon}}} = \frac{mv}{\frac{E}{c}} = \frac{mvc}{E}$$

where m is the mass of the atom.

The kinetic energy of an atom whose temperature is T is:

$$\tfrac{1}{2}mv^2 = \tfrac{3}{2}kT \Rightarrow v = \sqrt{\frac{3kT}{m}}$$

Substituting for v gives:

$$N = \frac{mc}{E}\sqrt{\frac{3kT}{m}} = \frac{c}{E}\sqrt{3mkT}$$

For an atom whose mass is 50 u:

$$N = \frac{2.998\times10^{8}\ \text{m/s}}{1\,\text{eV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}}\sqrt{3\left(50\,\text{u}\times\frac{1.661\times10^{-27}\ \text{kg}}{\text{u}}\right)\left(1.381\times10^{-23}\ \text{J/K}\right)\left(500\,\text{K}\right)}$$
$$\approx \boxed{10^{5}}$$

(*b*) The number N of ping-pong ball-bowling ball collisions needed to bring the bowling ball to rest is the ratio of the change in the momentum of the bowling ball as it stops to the momentum brought to the collision by each ping-pong ball:

$$N = \frac{\Delta p_{\text{bowling ball}}}{p_{\text{ping-pong ball}}} = \frac{m_{\text{bb}}v_{\text{bb}}}{m_{\text{ppb}}v_{\text{ppb}}}$$

Provided the speeds of the approaching bowling ball and ping-pong ball are approximately the same:

$$N = \frac{\Delta p_{\text{bowling ball}}}{p_{\text{ping-pong ball}}} \approx \frac{m_{\text{bb}}}{m_{\text{ppb}}} \approx \frac{6.0\,\text{kg}}{4.0\,\text{g}} \approx \boxed{10^{3}}$$

(*c*) The number of photons N needed to stop a ^{85}Rb atom is the ratio of the change in the momentum of the atom to the momentum brought to the collision by each photon:

$$N = \frac{\Delta p_{\text{atom}}}{p_{\text{photon}}} = \frac{mv}{\frac{h}{\lambda}} = \frac{mv\lambda}{h}$$

Substitute numerical values and evaluate N:

$$N = \frac{85\left(1.661\times10^{-27}\ \text{kg}\right)\left(300\,\text{m/s}\right)\left(780.24\,\text{nm}\right)}{6.626\times10^{-34}\ \text{J}\cdot\text{s}} = \boxed{5.08\times10^{4}}$$

The Bohr Model of the Hydrogen Atom

22 • The first Bohr radius is given by $a_0 = \hbar^2/\left(mke^2\right) = 0.0529\text{ nm}$ (Equation 36-12). Use the known values of the constants in the equation to show that a_0 is equal to 0.0529 nm.

Picture the Problem The radius of the first Bohr orbit is given by $a_0 = \dfrac{\hbar^2}{mke^2}$.

Equation 36-12 is:

$$a_0 = \frac{\hbar^2}{mke^2}$$

Substitute numerical values and evaluate a_0:

$$a_0 = \frac{\left(1.055\times10^{-34}\text{ J}\cdot\text{s}\right)^2}{\left(9.109\times10^{-31}\text{kg}\right)\left(8.988\times10^{9}\,\dfrac{\text{N}\cdot\text{m}^2}{\text{kg}^2}\right)\left(1.601\times10^{-19}\text{ C}\right)^2} = 5.30\times10^{-11}\text{ m}$$

$$= \boxed{0.0529\,\text{nm}}$$

23 • The longest wavelength in the Lyman series for the hydrogen atom was calculated in Example 36-2. Find the wavelengths for the transitions (*a*) $n_i = 3$ to $n_f = 1$ and (*b*) $n_i = 4$ to $n_f = 1$.

Picture the Problem We can use the equation relating the wavelength of the radiation emitted during a transition between two energy states to find the wavelengths for the transitions specified in the problem statement.

Express the wavelength of the radiation emitted during an energy transformation from one energy state to another:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E} = \frac{1240\,\text{eV}\cdot\text{nm}}{E_i - E_f}$$

provided the energies are expressed in eV. Note that this relationship tells us that the longest wavelength corresponds to the smallest energy difference.

Because $E_f = -13.6$ eV:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{E_i + 13.6\,\text{eV}}$$

Express the energy of the *n*th energy state of the atom:

$$E_n = -\frac{E_0}{n^2} = -\frac{13.6\,\text{eV}}{n^2}$$

Substitute for E_n and simplify to obtain:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{-\frac{13.6\,\text{eV}}{n_i^2}+13.6\,\text{eV}} = \frac{1240\,\text{eV}\cdot\text{nm}}{13.6\,\text{eV}\left(1-\frac{1}{n_i^2}\right)} \quad (1)$$

(a) Evaluate equation (1) for $n_i = 3$:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{13.6\,\text{eV}\left(1-\frac{1}{3^2}\right)} = \boxed{103\,\text{nm}}$$

(b) Evaluate equation (1) for $n_i = 4$:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{13.6\,\text{eV}\left(1-\frac{1}{4^2}\right)} = \boxed{97.3\,\text{nm}}$$

24 • Find the photon energies for the three longest wavelengths in the Balmer series for the hydrogen atom, and calculate the three wavelengths.

Picture the Problem For the Balmer series, $E_f = E_2 = -3.40$ eV. The wavelength associated with each transition is related to the difference in energy between the states by $\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{E_i - E_f}$.

Express the wavelength of the radiation emitted during an energy transformation from one energy state to another:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E} \quad (1)$$

provided the energies are expressed in eV. Note that this relationship tells us that the longest wavelength corresponds to the smallest energy difference.

Evaluate ΔE for the transition $n = 3$ to $n = 2$:

$$\Delta E_{n\to 2} = E_n - E_2 = \frac{E_0}{n^2} - E_2$$

Because $E_f = E_2 = -3.40$ eV and $E_0 = -13.6$ eV:

$$\Delta E_{n\to 2} = -\frac{13.6\,\text{eV}}{n^2} + 3.40\,\text{eV} \quad (2)$$

Evaluate equation (2) for $n = 3$:

$$\Delta E_{3\to 2} = -\frac{13.6\,\text{eV}}{3^2} + 3.40\,\text{eV} = \boxed{1.89\,\text{eV}}$$

Substitute in equation (1) to obtain:

$$\lambda_{3\to 2}=\frac{1240\,\text{eV}\cdot\text{nm}}{1.89\,\text{eV}}=\boxed{656\,\text{nm}}$$

Evaluate equation (2) for $n = 4$:

$$\Delta E_{4\to 2}=-\frac{13.6\,\text{eV}}{4^2}+3.40\,\text{eV}=\boxed{2.55\,\text{eV}}$$

Substitute in equation (1) to obtain:

$$\lambda_{4\to 2}=\frac{1240\,\text{eV}\cdot\text{nm}}{2.55\,\text{eV}}=\boxed{486\,\text{nm}}$$

Evaluate equation (2) for $n = 5$:

$$\Delta E_{5\to 2}=-\frac{13.6\,\text{eV}}{5^2}+3.40\,\text{eV}=\boxed{2.86\,\text{eV}}$$

Substitute in equation (1) to obtain:

$$\lambda_{5\to 2}=\frac{1240\,\text{eV}\cdot\text{nm}}{2.86\,\text{eV}}=\boxed{434\,\text{nm}}$$

25 •• (*a*) Find the photon energy and wavelength for the series limit (shortest wavelength) in the Paschen series ($n_f = 3$) for the hydrogen atom. (*b*) Calculate the wavelength for the three longest wavelengths in Paschen series.

Picture the Problem We can use Bohr's second postulate to relate the photon energy to its frequency and use $\lambda=\dfrac{1240\,\text{eV}\cdot\text{nm}}{E_\text{i}-E_\text{f}}$ to find the wavelengths of the three longest wavelengths in the Paschen series.

(*a*) Use Bohr's second postulate to express the energy of the photons in the Paschen series:

$$hf=\Delta E=E_\text{i}-E_\text{f} \qquad (1)$$

For the series limit:

$$n_\text{i}=\infty \text{ and } E_\text{i}=0$$

Substitute for n_i and E_i to obtain:

$$\Delta E=-E_\text{f}=-\left(-\frac{E_0}{n_\text{f}^2}\right)=\frac{E_0}{n_\text{f}^2}$$

Evaluate the photon energy for $n_\text{f} = 3$:

$$hf=\frac{13.6\,\text{eV}}{3^2}=\boxed{1.51\,\text{eV}}$$

Express the wavelength of the radiation resulting from an energy transition $\Delta E = hf$:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E} \qquad (2)$$

provided the energies are expressed in eV.

Evaluate λ_{min} for the transition $n_\text{i} = \infty$ to $n_\text{f} = 3$:

$$\lambda_{\text{min}} = \frac{1240\,\text{eV}\cdot\text{nm}}{1.51\,\text{eV}} = \boxed{821\,\text{nm}}$$

(*b*) For the three longest wavelengths:

$$n_\text{i} = 4, 5, \text{and } 6$$

Equation (1) becomes:

$$\begin{aligned} hf = E_\text{i} - E_\text{f} &= -\frac{E_0}{n_\text{i}^2} - \left(-\frac{E_0}{n_\text{f}^2}\right) \\ &= E_0\left(\frac{1}{n_\text{f}^2} - \frac{1}{n_\text{i}^2}\right) = E_0\left(\frac{1}{9} - \frac{1}{n_\text{i}^2}\right) \end{aligned} \qquad (3)$$

Evaluate equation (3) for $n_\text{i} = 4$:

$$\Delta E_{4\to 3} = (13.6\,\text{eV})\left(\frac{1}{9} - \frac{1}{16}\right) = \boxed{0.661\,\text{eV}}$$

Evaluate equation (2) for $\Delta E = 0.661$ eV:

$$\lambda_{4\to 3} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.661\,\text{eV}} = \boxed{1880\,\text{nm}}$$

Evaluate equation (3) for $n_\text{i} = 5$:

$$\Delta E_{5\to 3} = (13.6\,\text{eV})\left(\frac{1}{9} - \frac{1}{25}\right) = \boxed{0.967\,\text{eV}}$$

Evaluate equation (2) for $\Delta E = 0.967$ eV:

$$\lambda_{5\to 3} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.967\,\text{eV}} = \boxed{1280\,\text{nm}}$$

Evaluate equation (3) for $n_\text{i} = 6$:

$$\Delta E_{6\to 3} = (13.6\,\text{eV})\left(\frac{1}{9} - \frac{1}{36}\right) = \boxed{1.13\,\text{eV}}$$

Evaluate equation (2) for $\Delta E = 1.13$ eV:

$$\lambda_{6\to 3} = \frac{1240\,\text{eV}\cdot\text{nm}}{1.13\,\text{eV}} = \boxed{1100\,\text{nm}}$$

The positions of these lines on a horizontal linear scale are shown below with the wavelengths and transitions indicated.

```
  6→3       5→3                              4→3
---|---------|-------------------------------|-----
1100 nm   1280 nm                         1880 nm
```

26 •• (*a*) Find the photon energy and wavelength for the series limit (shortest wavelength) in the Brackett series ($n_f = 4$) for the hydrogen atom. (*b*) Calculate the wavelength for the three longest wavelengths in Brackett.

Picture the Problem We can use Bohr's second postulate to relate the photon energy to its frequency and use $\lambda = \dfrac{1240\,\text{eV}\cdot\text{nm}}{E_\text{i} - E_\text{f}}$ to find the wavelengths of the three longest wavelengths in the Brackett series.

(*a*) Use Bohr's second postulate to express the energy of the photons in the Paschen series:

$$hf = \Delta E = E_\text{i} - E_\text{f} \quad (1)$$

For the series limit:

$$n_\text{i} = \infty \text{ and } E_\text{i} = 0$$

Substitute to obtain:

$$\Delta E = -E_\text{f} = -\left(-\frac{E_0}{n_\text{f}^2}\right) = \frac{E_0}{n_\text{f}^2}$$

Evaluate the photon energy for $n_f = 4$:

$$hf = \frac{13.6\,\text{eV}}{4^2} = \boxed{0.850\,\text{eV}}$$

Express the wavelength of the radiation resulting from an energy transition $\Delta E = hf$:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E} \quad (2)$$

provided the energies are expressed in eV.

Evaluate λ_min for the transition $n_i = \infty$ to $n_f = 4$:

$$\lambda_\text{min} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.850\,\text{eV}} = \boxed{1460\,\text{nm}}$$

(*b*) For the three longest wavelengths:

$$n_\text{i} = 5, 6, \text{and } 7$$

Equation (1) becomes:

$$\begin{aligned}\Delta E = E_\text{i} - E_\text{f} &= -\frac{E_0}{n_\text{i}^2} - \left(-\frac{E_0}{n_\text{f}^2}\right) \\ &= E_0\left(\frac{1}{n_\text{f}^2} - \frac{1}{n_\text{i}^2}\right) = E_0\left(\frac{1}{16} - \frac{1}{n_\text{i}^2}\right)\end{aligned} \quad (3)$$

Evaluate equation (3) for $n_\text{i} = 5$:

$$\Delta E_{5\to 4} = (13.6\,\text{eV})\left(\frac{1}{16} - \frac{1}{25}\right) = \boxed{0.306\,\text{eV}}$$

Evaluate equation (2) for $\Delta E = 0.306$ eV:

$$\lambda_{5\to 4} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.306\,\text{eV}} = \boxed{4050\,\text{nm}}$$

Evaluate equation (3) for $n_\text{i} = 6$:

$$\Delta E_{6\to 4} = (13.6\,\text{eV})\left(\frac{1}{16} - \frac{1}{36}\right) = \boxed{0.472\,\text{eV}}$$

Evaluate equation (2) for $\Delta E = 0.472$ eV:

$$\lambda_{6\to 4} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.472\,\text{eV}} = \boxed{2630\,\text{nm}}$$

Evaluate equation (3) for $n_\text{i} = 7$:

$$\Delta E_{7\to 4} = (13.6\,\text{eV})\left(\frac{1}{16} - \frac{1}{49}\right) = \boxed{0.572\,\text{eV}}$$

Evaluate equation (2) for $\Delta E = 0.572$ eV:

$$\lambda_{7\to 4} = \frac{1240\,\text{eV}\cdot\text{nm}}{0.572\,\text{eV}} = \boxed{2170\,\text{nm}}$$

The positions of these lines on a horizontal linear scale are shown below with the wavelengths and transitions indicated.

```

```

27 ••• [SSM] In the center-of-mass reference frame of a hydrogen atom, the electron and nucleus have momenta that have equal magnitudes p and opposite directions. (a) Using the Bohr model, show that the total kinetic energy of the electron and nucleus can be written $K = p^2/(2\mu)$ where $\mu = m_\text{e}M/(M + m_\text{e})$ is called the reduced mass, m_e is the mass of the electron, and M is the mass of the

nucleus. (*b*) For the equations for the Bohr model of the atom, the motion of the nucleus can be taken into account by replacing the mass of the electron with the reduced mass. Use Equation 36-14 to calculate the Rydberg constant for a hydrogen atom that has a nucleus of mass $M = m_p$. Find the approximate value of the Rydberg constant by letting M go to infinity in the reduced mass formula. To how many figures does this approximate value agree with the actual value? (*c*) Find the percentage correction for the ground-state energy of the hydrogen atom by using the reduced mass in Equation 36-16. *Remark: In general, the reduced mass for a two-body problem with masses m_1 and m_2 is given by*

$$\mu = \frac{m_1 m_2}{m_1 + m_2}.$$

Picture the Problem We can express the total kinetic energy of the electron-nucleus system as the sum of the kinetic energies of the electron and the nucleus. Rewriting these kinetic energies in terms of the momenta of the electron and nucleus will lead to $K = p^2/2m_r$.

(*a*) Express the total kinetic energy of the electron-nucleus system:

$$K = K_e + K_n$$

Express the kinetic energies of the electron and the nucleus in terms of their momenta:

$$K_e = \frac{p^2}{2m_e} \text{ and } K_n = \frac{p^2}{2M}$$

Substitute and simplify to obtain:

$$K = \frac{p^2}{2m_e} + \frac{p^2}{2M} = \frac{p^2}{2}\left(\frac{1}{m_e} + \frac{1}{M}\right)$$

$$= \frac{p^2}{2}\left(\frac{M + m_e}{m_e M}\right) = \frac{p^2}{2\left(\dfrac{m_e M}{M + m_e}\right)}$$

$$= \boxed{\frac{p^2}{2\mu}}$$

provided we let $\mu = m_e M/(M + m_e)$.

(*b*) From Equation 36-14 we have:

$$R = \frac{m_r k^2 e^4}{4\pi c \hbar^3} = C\left(\frac{m_e}{1 + \dfrac{m_e}{M}}\right) \qquad (1)$$

where

$$C = \frac{k^2 e^4}{4\pi c \hbar^3}$$

Use the Table of Physical Constants at the end of the text to obtain:

$$C = 1.204663 \times 10^{37}\ \mathrm{m^{-1}/kg}$$

For H:

$$R_{\mathrm{H}} = C\left(\frac{m_{\mathrm{e}}}{1+\dfrac{m_{\mathrm{e}}}{m_{\mathrm{p}}}}\right)$$

Substitute numerical values and evaluate R_{H}:

$$\begin{aligned} R_{\mathrm{H}} &= \left(1.204663 \times 10^{37}\ \frac{\mathrm{m^{-1}}}{\mathrm{kg}}\right)\left(\frac{9.10938188 \times 10^{-31}\ \mathrm{kg}}{1+\dfrac{9.10938188 \times 10^{-31}\ \mathrm{kg}}{1.67262158 \times 10^{-27}\ \mathrm{kg}}}\right) \\ &= \boxed{1.096850 \times 10^{7}\ \mathrm{m^{-1}}} \end{aligned}$$

Let $M \to \infty$ in equation (1) to obtain $R_{\mathrm{H,approx}}$:

$$R_{\mathrm{H,approx}} = Cm_{\mathrm{e}}$$

Substitute numerical values and evaluate $R_{\mathrm{H,approx}}$:

$$\begin{aligned} R_{\mathrm{H,approx}} &= \left(1.204663 \times 10^{37}\ \mathrm{m^{-1}/kg}\right)\left(9.10938188 \times 10^{-31}\ \mathrm{kg}\right) \\ &= \boxed{1.097448 \times 10^{7}\ \mathrm{m^{-1}}} \end{aligned}$$

R_{H} and $R_{\mathrm{H,approx}}$ agree to three significant figures.

(*c*) Express the ratio of the kinetic energy K of the electron in its orbit about a stationary nucleus to the kinetic energy of the reduced-mass system K':

$$\begin{aligned} \frac{K}{K'} &= \frac{\dfrac{p^2}{2m_{\mathrm{e}}}}{\dfrac{p^2}{2\mu}} = \frac{\mu}{m_{\mathrm{e}}} = \frac{1}{m_{\mathrm{e}}}\left(\frac{m_{\mathrm{p}}m_{\mathrm{e}}}{m_{\mathrm{p}}+m_{\mathrm{e}}}\right) \\ &= \frac{m_{\mathrm{p}}}{m_{\mathrm{p}}+m_{\mathrm{e}}} = \frac{1}{1+\dfrac{m_{\mathrm{e}}}{m_{\mathrm{p}}}} \end{aligned}$$

Substitute numerical values and evaluate the ratio of the kinetic energies:

$$\frac{K}{K'}=\frac{1}{1+\dfrac{9.10938188\times10^{-31}\text{ kg}}{1.67262158\times10^{-27}\text{ kg}}}=0.999455$$

or

$$K=0.999455K'$$

and the correction factor is the ratio of the masses or $\boxed{0.0545\%}$

Remarks: **The correct energy is slightly less than that calculated neglecting the motion of the nucleus.**

28 •• The Pickering series of the spectrum of He^+ (singly-ionized helium) consists of spectral lines due to transitions to the $n = 4$ state of He^+. Every other line of the Pickering series is very close to a spectral line in the Balmer series for hydrogen transitions to $n = 2$. (*a*) Show that this statement is accurate. (*b*) Calculate the wavelength of the photon during a transition from the $n = 6$ level to the $n = 4$ level of He^+, and show that it corresponds to one of the Balmer series lines.

Picture the Problem We can use Equation 36-15 with $Z = 2$ to explain how it is that every other line of the Pickering series is very close to a line in the Balmer series. We can use the relationship between the energy difference between two quantum states and the wavelength of the photon emitted during a transition from the higher state to the lower state to find the wavelength of the photon corresponding to a transition from the $n = 6$ to the $n = 4$ level of He^+.

(*a*) From Equation 36-15, the energy levels of an atom are given by:

$$E_n=-Z^2\frac{E_0}{n^2}$$

where E_0 is the ground state energy (13.6 eV).

For He^+, $Z = 2$ and:

$$E_n=-4\frac{E_0}{n^2}$$

Because of this, an energy level with even principal quantum number n in He^+ will have the same energy as a level with quantum number $n/2$ in H. Therefore, a transition between levels with principal quantum numbers $2m$ and $2p$ in He^+ will have almost the same energy as a transition between level m and p in H. In particular, transitions from $2m$ to $2p = 4$ in He^+ will have the same energy as transitions from m to $n = 2$ in H (the Balmer series).

(*b*) Transitions between these energy levels result in the emission or absorption of a photon whose wavelength is given by:

$$\lambda = \frac{hc}{E_6 - E_4} \qquad (1)$$

Evaluate E_6 and E_4:

$$E_6 = -4\left(\frac{13.6\,\text{eV}}{6^2}\right) = -1.51\,\text{eV}$$

and

$$E_4 = -4\left(\frac{13.6\,\text{eV}}{4^2}\right) = -3.40\,\text{eV}$$

Substitute for E_6 and E_4 in equation (1) and evaluate λ:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{-1.51\,\text{eV} - (-3.40\,\text{eV})} = \boxed{656\,\text{nm}}$$

which is the same as the $n = 3$ to $n = 2$ transition in H.

Quantum Numbers in Spherical Coordinates

29 • For an electron in an atom that has an orbital quantum number $\ell = 1$, find (*a*) the magnitude of the angular momentum *L* and (*b*) the possible values of the magnetic quantum number m_ℓ. (*c*) Draw a vector diagram to scale showing the possible orientations of $\vec{L}$ relative to the +*z* direction.

Picture the Problem We can use the expression relating *L* to ℓ to find the magnitude of the angular momentum and the constraints on the quantum numbers to determine the allowed values for *m*.

(*a*) Express the angular momentum as a function of ℓ:

$$L = \sqrt{\ell(\ell+1)}\hbar$$

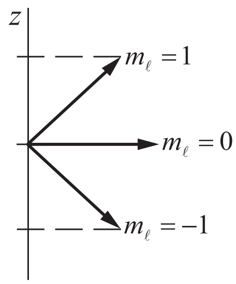
Substitute numerical values and evaluate *L*:

$$L = \sqrt{1(1+1)}\hbar = \sqrt{2}\hbar$$
$$= \sqrt{2}\left(1.055\times10^{-34}\,\text{J}\cdot\text{s}\right)$$
$$= \boxed{1.49\times10^{-34}\,\text{J}\cdot\text{s}}$$

(*b*) Because $m_\ell = -\ell, \ldots, 0, \ldots, \ell$ the allowed values for $\ell = 1$ are:

$$m_\ell = \boxed{-1, 0, +1}$$

(*c*) The vector diagram is shown on the right. Note that because $L_z = m_\ell \hbar$ and $L = \sqrt{2}\hbar$, the vectors for $m_\ell = -1$ and $m_\ell = 1$ must make angles of 45° with the z axis.



30 • For an electron in an atom that has an orbital quantum number $\ell = 3$, find (*a*) the magnitude of the angular momentum L and (*b*) the possible values of m_ℓ. (*c*) Draw a vector diagram to scale showing the possible orientations of $\vec{L}$ relative to the $+z$ direction.

Picture the Problem We can use the expression relating L to ℓ to find the magnitude of the angular momentum and the constraints on the quantum numbers to determine the allowed values for m.

(*a*) Express the angular momentum as a function of ℓ:

$$L = \sqrt{\ell(\ell+1)}\hbar$$

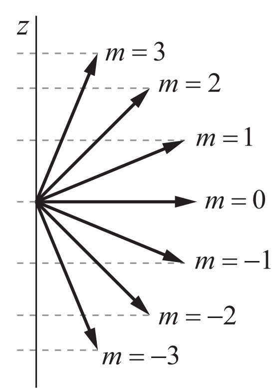
Substitute numerical values and evaluate L:

$$L = \sqrt{3(3+1)}\hbar = 2\sqrt{3}\hbar = 2\sqrt{3}\left(1.055\times10^{-34}\ \text{J}\cdot\text{s}\right) = \boxed{3.65\times10^{-34}\ \text{J}\cdot\text{s}}$$

(*b*) Because $m_\ell = -\ell, \ldots, 0, \ldots, \ell$ the allowed values for $\ell = 3$ are:

$$m_\ell = \boxed{-3, -2, -1, 0, +1, +2, +3}$$

(*c*) The vector diagram is shown on the right. Note that because $L_z = m_\ell \hbar$ and $L = 2\sqrt{3}\hbar$, the angles between the vectors and the z axis are determined by $\cos\theta_m = m_\ell / 2\sqrt{3}$. Thus $\theta_3 = 30°$, $\theta_2 = 54.7°$, and $\theta_1 = 73.2°$. The spacing between the allowed values of L_z is constant and equal to $\hbar$.



31 • An electron in an atom has principle quantum number $n = 3$. (*a*) What are the possible values of ℓ? (*b*) What are the possible combinations of ℓ and m_ℓ. (*c*) Using the fact that there are two quantum states for each combination of ℓ and m_ℓ because of electron spin, find the total number of electron states for $n = 3$.

Picture the Problem We can find the possible values of ℓ by using the constraints on the quantum numbers. A more analytical solution is to first derive the number of electron states for an arbitrary value of n and then substitute the specific value of n.

(*a*) When $n = 3$: $\ell = \boxed{0,1,2}$

(*b*) For $\ell = 0$: $m_\ell = \boxed{0}$

For $\ell = 1$: $m_\ell = \boxed{-1,0,+1}$

For $\ell = 2$: $m_\ell = \boxed{-2,-1,0,+1,+2}$

(*c*) We can find the total number of electron states by enumerating the possibilities as shown in the table.

n	ℓ	m_ℓ
3	0	0
3	1	−1
3	1	0
3	1	1
3	2	−2
3	2	−1
3	2	0
3	2	1
3	2	2

Note that there are 9 states. Because *N,* the number of electron states is twice the number of m_ℓ states, the number of electron states is $\boxed{18}$.

Alternatively, we can derive an expression for the number of electron states for an arbitrary value of n and then substitute specific values of n.

The number of m_ℓ states for a given n is given by:

$$N_m = \sum_{\ell=0}^{n-1}(2\ell+1) = 2\sum_{\ell=0}^{n-1}\ell + \sum_{\ell=0}^{n-1}(1)$$

Express the sum of all integers from 0 to p:

$$\sum_{\ell=0}^{p}\ell = \tfrac{1}{2}p(p+1)$$

Use this result to evaluate $2\sum_{\ell=0}^{n-1}\ell$:

$$2\sum_{\ell=0}^{n-1}\ell = 2\left[\tfrac{1}{2}(n-1)n\right] = n^2 - n$$

Evaluate the second term to obtain: $\sum_{\ell=0}^{n-1}(1) = n$

Substitute to obtain: $N_m = n^2 - n + n = n^2$

and, because N, the number of electron states is twice the number of m states, the number of electron states is $N = 2n^2$.

Hence, for $n = 3$, the number of electron states is: $N = 2n^2 = 2(3)^2 = \boxed{18}$

32 • In an atom, find the total number of electron states that have (*a*) $n = 4$ and (*b*) $n = 2$. (See Problem 33.)

Picture the Problem While we could find the number of electron states by finding the possible values of ℓ from the constraints on the quantum numbers and then enumerating the states, we'll take a more analytical approach by deriving an expression for the number of electron states for an arbitrary value of n and then substitute specific values of n.

The number of m states for a given n is given by: $N_m = \sum_{\ell=0}^{n-1}(2\ell+1) = 2\sum_{\ell=0}^{n-1}\ell + \sum_{\ell=0}^{n-1}(1)$

Express the sum of all integers from 0 to p: $\sum_{\ell=0}^{p}\ell = \frac{1}{2}p(p+1)$

Use this result to evaluate $2\sum_{\ell=0}^{n-1}\ell$: $2\sum_{\ell=0}^{n-1}\ell = 2\left[\frac{1}{2}(n-1)n\right] = n^2 - n$

Evaluate the second term to obtain: $\sum_{\ell=0}^{n-1}(1) = n$

Substitute to obtain: $N_m = n^2 - n + n = n^2$

and, because N, the number of electron states is twice the number of m states, the number of electron states is $N = 2n^2$.

(*a*) For $n = 4$, the number of electron states is: $N = 2n^2 = 2(4)^2 = \boxed{32}$

(*b*) For $n = 2$, the number of electron states is:

$$N = 2n^2 = 2(2)^2 = \boxed{8}$$

33 •• **[SSM]** Find the minimum value of the angle θ between $\vec{L}$ and the $+z$ direction for an electron in an atom that has (*a*) $\ell = 1$, (*b*) $\ell = 4$, and (*c*) $\ell = 50$.

Picture the Problem The minimum angle between the *z* axis and $\vec{L}$ is the angle between the $\vec{L}$ vector for $m = \ell$ and the *z* axis.

Express the angle θ as a function of L_z and L:

$$\theta = \cos^{-1}\left(\frac{L_z}{L}\right)$$

Relate the *z* component of $\vec{L}$ to m_ℓ and ℓ:

$$L_z = m_\ell \hbar = \ell\hbar$$

Express the angular momentum L:

$$L = \sqrt{\ell(\ell+1)}\hbar$$

Substitute to obtain:

$$\theta = \cos^{-1}\left(\frac{\ell\hbar}{\sqrt{\ell(\ell+1)}\hbar}\right) = \cos^{-1}\left(\sqrt{\frac{\ell}{\ell+1}}\right)$$

(*a*) For $\ell = 1$:

$$\theta = \cos^{-1}\left(\sqrt{\frac{1}{1+1}}\right) = \boxed{45.0^\circ}$$

(*b*) For $\ell = 4$:

$$\theta = \cos^{-1}\left(\sqrt{\frac{4}{4+1}}\right) = \boxed{26.6^\circ}$$

(*c*) For $\ell = 50$:

$$\theta = \cos^{-1}\left(\sqrt{\frac{50}{50+1}}\right) = \boxed{8.05^\circ}$$

34 •• What are the possible values of n and m_ℓ for an electron in an atom that has (*a*) $\ell = 3$, (*b*) $\ell = 4$, and (*c*) $\ell = 0$?

Picture the Problem We can use constraints on the quantum numbers in spherical coordinates to find the possible values of n and m_ℓ for each of the values of ℓ.

The constraints on n, m_ℓ, and ℓ are:

$n = 1, 2, 3, ...$
$\ell = 0, 1, 2, ..., n - 1$
$m_\ell = -\ell, (-\ell + 1), ... 0, 1, 2, ... \ell$

(*a*) For $\ell = 3$: $\boxed{n \geq 4 \text{ and } m_\ell = -3, -2, -1, 0, 1, 2, 3}$

(*b*) For $\ell = 4$: $\boxed{n \geq 5 \text{ and } m_\ell = -4, -3, -2, -1, 0, 1, 2, 3, 4}$

(*c*) For $\ell = 0$: $\boxed{n \geq 1 \text{ and } m_\ell = 0}$

35 •• For an electron in an atom that is in an $\ell = 2$ state, find (*a*) the magnitude of the angular momentum squared L^2, (*b*) the maximum value of L_z^2, and (*c*) the smallest value of $L_x^2 + L_y^2$.

Picture the Problem The magnitude of the orbital angular momentum L of an electron in an atom is related to the orbital quantum number ℓ by $L = \sqrt{\ell(\ell+1)}\hbar$ and the z component of the angular momentum of the electron is given by $L_z = m\hbar$.

(*a*) For the $\ell = 2$ state, the square magnitude of the angular momentum is:

$$L^2 = 2(2+1)\hbar^2 = \boxed{6\hbar^2}$$

(*b*) For the $\ell = 2$ state, the maximum value of L_z^2 is:

$$L_z^2 = 2^2\hbar^2 = \boxed{4\hbar^2}$$

(*c*) The smallest value of $L_x^2 + L_y^2$ is given by:

$$L_x^2 + L_y^2 = L^2 - L_z^2 = 6\hbar^2 - 4\hbar^2 = \boxed{2\hbar^2}$$

Quantum Theory of the Hydrogen Atom

36 • For the ground state of the hydrogen atom, find the values of (*a*) $\psi(r)$ at $r = a_0$, (*b*) $\psi^2(r)$ at $r = a_0$, and (*c*) the radial probability density $P(r)$ at $r = a_0$. Give your answers in terms of a_0.

Picture the Problem We can use $\psi(r) = \frac{1}{\sqrt{\pi}}\left(\frac{Z}{a_0}\right)^{3/2} e^{-Zr/a_0}$ to evaluate the normalized ground-state wave function and its square at $r = a_0$ and $P(r) = 4\pi r^2|\psi|^2$ to find the radial probability density at the same location.

(*a*) Noting that $Z = 1$ for hydrogen, evaluate $\psi(a_0)$ to obtain:

$$\psi(a_0) = \frac{1}{\sqrt{\pi}}\left(\frac{1}{a_0}\right)^{3/2} e^{-a_0/a_0}$$

$$= \boxed{\frac{1}{ea_0\sqrt{\pi a_0}}}$$

where e is the base of the natural logarithms.

(*b*) Square $\psi(a_0)$ to obtain:

$$\psi^2(a_0) = \left(\frac{1}{ea_0\sqrt{\pi a_0}}\right)^2 = \boxed{\frac{1}{e^2 a_0^3 \pi}}$$

where e is the base of the natural logarithms.

(*c*) Use the result from Part (*b*) to evaluate $P(a_0)$:

$$P(a_0) = 4\pi a_0^2 |\psi|^2 = 4\pi a_0^2\left(\frac{1}{e^2 a_0^3 \pi}\right)$$

$$= \boxed{\frac{4}{e^2 a_0}}$$

where e is the base of the natural logarithms.

37 • (*a*) If electron spin is not included, how many different wave functions are there corresponding to the first excited energy level $n = 2$ for a hydrogen atom? (*b*) Specify the quantum numbers for each of these wave functions.

Picture the Problem We can use the constraints on n, ℓ and m to determine the number of different wave functions, excluding spin, corresponding to the first excited energy state of hydrogen.

For $n = 2$: $\ell = 0$ or 1

(*a*) For $\ell = 0$, $m_\ell = 0$ and we have: 1 state

For $\ell = 1$, $m_\ell = -1, 0, +1$ and we have: 3 states

Hence, for $n = 2$ we have: $\boxed{4\text{ states}}$

(*b*) The four wave functions are summarized to the right.

n	ℓ	m_ℓ	(n, ℓ, m_ℓ)
2	0	0	(2,0,0)
2	1	−1	(2,1,−1)
2	1	0	(2,1,0)
2	1	1	(2,1,1)

38 •• For the ground state of the hydrogen atom, calculate the probability of finding the electron in the region between r and $r + \Delta r$, where $\Delta r = 0.03a_0$ and (*a*) $r = a_0$ and (*b*) $r = 2a_0$.

Picture the Problem We can use $\psi(r) = \frac{1}{\sqrt{\pi}}\left(\frac{Z}{a_0}\right)^{3/2} e^{-Zr/a_0}$ to evaluate the normalized ground-state wave function and its square and $P(r) = 4\pi r^2|\psi|^2$ to find the radial probability density at the same location. Because the range Δr is so small, the variation in the radial probability density $P(r)$ can be neglected. The probability of finding the electron in some small range Δr is then $P(r)\,\Delta r$.

Express the probability of finding the electron in the range Δr:

$$\text{Prob} = \int P(r)dr \qquad (1)$$

where $P(r)$ is the radial probability density function.

The radial probability density function is:

$$P(r) = 4\pi r^2|\psi|^2 \qquad (2)$$

Express the normalized ground-state wave function:

$$\psi(r) = \frac{1}{\sqrt{\pi}}\left(\frac{Z}{a_0}\right)^{3/2} e^{-Zr/a_0}$$

Evaluate the normalized ground-state wave function evaluated at $r = a_0$ to obtain:

$$\psi(a_0) = \frac{1}{\sqrt{\pi}}\left(\frac{1}{a_0}\right)^{3/2} e^{-a_0/a_0} = \frac{1}{ea_0\sqrt{\pi a_0}}$$

Square $\psi(a_0)$ to obtain:

$$\psi^2(a_0) = \left(\frac{1}{ea_0\sqrt{\pi a_0}}\right)^2 = \frac{1}{e^2a_0^3\pi}$$

Substitute in equation (2) to obtain:

$$P(a_0) = 4\pi a_0^2|\psi|^2 = 4\pi a_0^2\left(\frac{1}{e^2a_0^3\pi}\right)$$

$$= \frac{4}{e^2a_0}$$

(*a*) Substitute in equation (1) to find the probability of finding the electron in the small range $\Delta r = 0.03a_0$:

$$\text{Prob} = \int P(a_0)dr \approx P(a_0)\Delta r$$
$$= \frac{4}{e^2 a_0}(0.03a_0) = \boxed{0.02}$$

(*b*) Evaluate the normalized ground-state wave function at $r = 2a_0$ to obtain:

$$\psi(2a_0) = \frac{1}{\sqrt{\pi}}\left(\frac{1}{a_0}\right)^{3/2} e^{-2a_0/a_0}$$
$$= \frac{1}{e^2 a_0 \sqrt{\pi a_0}}$$

Squaring $\psi(2a_0)$ yields:

$$\psi^2(2a_0) = \left(\frac{1}{e^2 a_0 \sqrt{\pi a_0}}\right)^2 = \frac{1}{e^4 a_0^3 \pi}$$

Substitute in equation (2) to obtain:

$$P(2a_0) = 4\pi(2a_0)^2|\psi|^2 = 16\pi a_0^2\left(\frac{1}{e^4 a_0^3 \pi}\right)$$
$$= \frac{16}{e^4 a_0}$$

Substitute in equation (1) to find the probability of finding the electron in some small range $\Delta r = 0.03a_0$:

$$\text{Prob} = \int P(2a_0)dr \approx P(2a_0)\Delta r$$
$$= \frac{16}{e^4 a_0}(0.03a_0)$$
$$= \boxed{0.009}$$

Remarks: There is about a 2% chance of finding the electron in this range at $r = a_0$, but at $r = 2a_0$, the chance is only about 0.9%.

39 •• The value of the constant C_{200} in the equation

$$\psi_{200} = C_{200}\left(2 - \frac{Zr}{a_0}\right)e^{-Zr/(2a_0)} \text{ (Equation 36-35)}$$

is given by $C_{2,0,0} = \frac{1}{4\sqrt{2\pi}}\left(\frac{Z}{a_0}\right)^{3/2}$. Find the values of (*a*) $\psi(r)$ at $r = a_0$, (*b*) $\psi^2(r)$ at $r = a_0$, and (*c*) the radial probability density $P(r)$ at $r = a_0$ for the state $n = 2$, $\ell = 0$, and $m_l = 0$ of a hydrogen atom. Give your answers in terms of a_0.

Picture the Problem We can use Equation 36-35 and the given expression for C_{200} to evaluate the spherically symmetric wave function ψ for $n = 2$, $\ell = 0$, $m_\ell = 0$, and $Z = 1$ and then use this result to evaluate ψ^2 and $P(r)$ for $r = a_0$.

(*a*) Express the spherically symmetric wave function for $n = 2$, $\ell = 0$, $m_\ell = 0$, and $Z = 1$ (Equation 36-35):

$$\psi_{200} = C_{200}\left(2-\frac{r}{a_0}\right)e^{-r/2a_0} = \frac{1}{4\sqrt{2\pi}}\left(\frac{1}{a_0}\right)^{3/2}\left(2-\frac{r}{a_0}\right)e^{-r/2a_0}$$

Evaluate this expression for $r = a_0$:

$$\psi_{200}(a_0) = \frac{1}{4\sqrt{2\pi}}\left(\frac{1}{a_0}\right)^{3/2}\left(2-\frac{a_0}{a_0}\right)e^{-a_0/2a_0} = \frac{1}{4\sqrt{2e\pi}\,a_0^{3/2}} = \boxed{\frac{0.0605}{a_0^{3/2}}}$$

where e is the base of the natural logarithms.

(*b*) Squaring $\psi_{200}(a_0)$ gives:

$$[\psi_{200}(a_0)]^2 = \left(\frac{0.0605}{a_0^{3/2}}\right)^2 = \boxed{\frac{0.00366}{a_0^3}}$$

(*c*) The radial probability density is given by:

$$P(r) = 4\pi r^2\psi^2(r)$$

Substitute for $\psi^2(r)$ and simplify to obtain:

$$P(a_0) = 4\pi a_0^2\left(\frac{0.00366}{a_0^3}\right) = \boxed{\frac{0.0460}{a_0}}$$

40 ••• Show that the radial probability density for the $n = 2$, $\ell = 1$, and $m_\ell = 0$ state of a one-electron atom can be written as $P(r) = A\cos^2\theta\, r^4 e^{-Zr/a_0}$, where A is a constant.

Picture the Problem We can use the definition of the radial probability density and the wave function (Equation 36-36) for the state (2, 1, 0) to obtain the result given in the problem statement.

Using Equation 36-36, express the wave function for the state (2, 1, 0):

$$\psi_{210}(r) = C_{210}\frac{Zr}{a_0}e^{-Zr/2a_0}\cos\theta$$

Square $\psi_{210}(r)$ to obtain:

$$[\psi_{210}(r)]^2 = \left(C_{210}\frac{Zr}{a_0}e^{-Zr/2a_0}\cos\theta\right)^2 = C_{210}^2\frac{Z^2r^2}{a_0^2}e^{-Zr/a_0}\cos^2\theta$$

Express the radial probability density:

$$P(r) = 4\pi r^2\psi^2(r)$$

Substitute for $\psi^2(r)$ and simplify to obtain:

$$P(r) = 4\pi r^2 C_{210}^2\frac{Z^2r^2}{a_0^2}e^{-Zr/a_0}\cos^2\theta = \boxed{Ar^4\cos^2\theta\, e^{-Zr/a_0}}$$

where

$$A == \boxed{\frac{4\pi C_{210}^2 Z^2}{a_0^2}}$$

41 ••• Calculate the probability of finding the electron in the region between r and $r + \Delta r$, where $\Delta r = 0.02a_0$ and (*a*) $r = a_0$ and (*b*) $r = 2a_0$ for the state $n = 2$, $\ell = 0$, and $m_l = 0$ in hydrogen. (See Problem 41 for the value of C_{200}.)

Picture the Problem In this instance, $\int P(r)dr$ extends over a sufficiently narrow interval $\Delta r << 0.02a_0$ that we can neglect the dependence of $P(r)$ on r. Hence, we can set $\int P(r)dr = P(r)\Delta r$ and use the wave function (Equation 36-35) for the state (2, 0, 0) and the expression for C_{200} from Problem 41 to find ψ_{200}, ψ_{200}^2, $P(r)$, and the probability of finding the electron in the range specified at $r = a_0$ and $r = 2a_0$.

(*a*) Express the probability of finding the electron in the range Δr:

$$\text{Prob} = \int P(r)dr \qquad (1)$$

where $P(r)$ is the radial probability density function.

The radial probability density function is:

$$P(r) = 4\pi r^2|\psi|^2 \qquad (2)$$

The normalized wave function for the (2, 0, 0) state of hydrogen is given by Equation 36-35:

$$\psi_{200}(r) = C_{200}\left(2 - \frac{r}{a_0}\right)e^{-r/2a_0}$$

From Problem 41 we have, for hydrogen:

$$C_{200} = \frac{1}{4\sqrt{2\pi}}\left(\frac{1}{a_0}\right)^{3/2}$$

Substitute to obtain:

$$\psi_{200}(r) = C_{200}\left(2 - \frac{r}{a_0}\right)e^{-r/2a_0}$$

$$= \frac{1}{4\sqrt{2\pi}}\left(\frac{1}{a_0}\right)^{3/2}\left(2 - \frac{r}{a_0}\right)e^{-r/2a_0}$$

Evaluate the normalized ground-state wave function at $r = a_0$ to obtain:

$$\psi_{200}(a_0) = \frac{1}{4\sqrt{2\pi}}\left(\frac{1}{a_0}\right)^{3/2} e^{-a_0/2a_0}$$

$$= \frac{1}{4\sqrt{2\pi e}a_0^{3/2}} = \frac{0.0605}{a_0^{3/2}}$$

Square $\psi_{200}(a_0)$ to obtain:

$$[\psi_{200}(a_0)]^2 = \left(\frac{0.0605}{a_0^{3/2}}\right)^2 = \frac{0.00366}{a_0^3}$$

Substitute for $\psi^2(r)$ in equation (2) to obtain:

$$P(a_0) = 4\pi a_0^2\psi^2(a_0) = 4\pi a_0^2\left(\frac{0.00366}{a_0^3}\right)$$

$$= \frac{4\pi(0.00366)}{a_0} = \frac{0.0460}{a_0}$$

Substitute in equation (1) to find the probability of finding the electron in some small range $\Delta r = 0.02\ a_0$:

$$\text{Prob} = \int P(a_0)dr \approx P(a_0)\Delta r$$

$$= \frac{0.0460}{a_0}(0.02a_0)$$

$$= \boxed{9\times10^{-4}}$$

(*b*) Evaluate the normalized ground-state wave function at $r = 2a_0$ to obtain:

$$\psi_{200}(2a_0) = \frac{1}{4\sqrt{2\pi}}\left(\frac{1}{a_0}\right)^{3/2}\left(2 - \frac{2a_0}{a_0}\right)e^{-2a_0/2a_0} = 0$$

Squaring $\psi_{200}(2a_0)$ gives:

$$[\psi_{200}(a_0)]^2 = 0$$

Substitute for $\psi^2(r)$ in equation (2) to obtain:

$$P(2a_0) = 0$$

Substitute in equation (1) to find the probability of finding the electron in some small range $\Delta r = 0.02\ a_0$:

$$\text{Prob} = \int P(2a_0)dr \approx P(2a_0)\Delta r = \boxed{0}$$

42 •• Show that the ground-state hydrogen atom wave function $\psi_{100} = \pi^{-1/2}\left(Z/a_0\right)^{3/2} e^{-Zr/a_0}$ (Equation 36-32) is a solution to Schrödinger's equation in spherical coordinates:

$$\frac{-\hbar^2}{2mr^2}\left\{\frac{\partial}{\partial r}\left(r^2\frac{\partial \psi}{\partial r}\right)+\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\psi}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2\psi}{\partial\phi^2}\right]\right\}+U(r)\psi = E\psi$$

where $U(r) = kZe^2/r$ (Equation 36-25).

Picture the Problem We wish to show that $\psi_{100} = \frac{1}{\sqrt{\pi}}\left(\frac{Z}{a_0}\right)^{3/2} e^{-Zr/a_0} = Ce^{-Zr/a_0}$ is a solution to $\frac{-\hbar^2}{2mr^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\psi}{\partial r}\right)+U(r)\psi = E\psi$, where $U(r) = -\frac{kZe^2}{r}$. Because the ground state is spherically symmetric, we do not need to consider the angular partial derivatives in Equation 36-32.

The normalized ground-state wave function is:

$$\psi_{100} = \frac{1}{\sqrt{\pi}}\left(\frac{Z}{a_0}\right)^{3/2} e^{-Zr/a_0} = Ce^{-Zr/a_0}$$

Differentiate this expression with respect to r to obtain:

$$\frac{\partial\psi_{100}}{\partial r} = C\frac{\partial}{\partial r}\left[e^{-Zr/a_0}\right] = -C\frac{Z}{a_0}e^{-Zr/a_0}$$

Multiply both sides of this equation by r^2:

$$r^2\frac{\partial\psi_{100}}{\partial r} = -C\frac{Z}{a_0}r^2e^{-Zr/a_0}$$

Differentiate this expression with respect to r to obtain:

$$\frac{\partial}{\partial r}\left(r^2\frac{\partial\psi_{100}}{\partial r}\right) = -C\frac{Z}{a_0}\frac{\partial}{\partial r}\left(r^2e^{-Zr/a_0}\right) = \left[-\frac{2Zr}{a_0}+r^2\left(\frac{Z}{a_0}\right)^2\right]Ce^{-Zr/a_0}$$

Substitute in Schrödinger's equation to obtain:

$$\frac{-\hbar^2}{2mr^2}\left[-\frac{2Zr}{a_0}+r^2\left(\frac{Z}{a_0}\right)^2\right]Ce^{-Zr/a_0} - \frac{kZe^2}{r}Ce^{-Zr/a_0} = ECe^{-Zr/a_0}$$

Solving for E yields:

$$E=\frac{-\hbar^2}{2mr^2}\left[-\frac{2Zr}{a_0}+r^2\left(\frac{Z}{a_0}\right)^2\right]-\frac{kZe^2}{r}$$

Because $a_0=\dfrac{\hbar^2}{mke^2}$:

$$E=\frac{-\hbar^2}{2mr^2}\left[-\frac{2mke^2Zr}{\hbar^2}+r^2\left(\frac{Zmke^2}{\hbar^2}\right)^2\right]-\frac{kZe^2}{r}=\frac{kZe^2}{r}-\frac{Z^2k^2e^4m}{2\hbar^2}-\frac{kZe^2}{r}$$

$$=\boxed{-\frac{Z^2k^2e^4m}{2\hbar^2}}$$

Because this is the correct ground state energy, we have shown that Equation 36-32 is a solution to Schrödinger's Equation with the potential energy function given by Equation 36-25.

43 •• Show by dimensional analysis that the expression for the hydrogen atom ground-state energy given by $E_0=\frac{1}{2}mk^2e^4/\hbar^2$ (Equation 36-27) has the dimensions of energy.

Picture the Problem For the purposes of this problem, we'll take unit analysis and dimensional analysis to be interchangeable. Then we can substitute for the units of the physical quantities in Equation 36-27 and simplify the result to show that the expression for the hydrogen atom ground-state energy has the units of energy.

Equation 36-27 is:

$$E_0=\frac{mk^2e^4}{2\hbar^2}$$

Substituting the units of m, k, e, and $\hbar$ and simplifying yields:

$$\frac{\mathrm{kg}\left[\dfrac{\mathrm{N\cdot m^2}}{\mathrm{C^2}}\right]^2[\mathrm{C}]^4}{[\mathrm{J\cdot s}]^2}=\frac{\mathrm{kg}\left[\mathrm{N\cdot m^2}\right]^2}{[\mathrm{N\cdot m\cdot s}]^2}=\frac{\mathrm{kg\cdot m^2}}{\mathrm{s^2}}=\boxed{\mathrm{J}}$$

Because the joule is a unit of energy, we can conclude that the expression for the ground-state energy given by Equation 36-27 has the dimensions of energy.

44 •• By dimensional analysis, show that the expression for the first Bohr radius given by $a_0\,\hbar^2/(mke^2)$ (Equation 36-12) has the dimensions of length.

Picture the Problem For the purposes of this problem, we'll take unit analysis and dimensional analysis to be interchangeable. Then we can substitute for the units of the physical quantities in the expression for the Bohr radius and simplify the result to show that the expression for the first Bohr radius has the units of length.

Equation 36-12 is:

$$a_0 = \frac{\hbar^2}{mke^2}$$

Substituting the units of *m, k, e,* and $\hbar$ and simplifying yields:

$$\frac{[\mathrm{J\cdot s}]^2}{\mathrm{kg}\cdot\dfrac{\mathrm{N\cdot m^2}}{\mathrm{C^2}}\cdot\mathrm{C^2}} = \frac{[\mathrm{N\cdot m\cdot s}]^2}{\mathrm{kg}\cdot\dfrac{\mathrm{N\cdot m^2}}{\mathrm{C^2}}\cdot\mathrm{C^2}} = \frac{\mathrm{N\cdot s^2}}{\mathrm{kg}} = \frac{\mathrm{kg}\cdot\dfrac{\mathrm{m}}{\mathrm{s^2}}\cdot\mathrm{s^2}}{\mathrm{kg}} = \boxed{\mathrm{m}}$$

Because the meter is a unit of length, we can conclude that the expression for the first Bohr radius has the dimensions of length.

45 •• The radial probability distribution function for a one-electron atom in its ground state can be written $P(r) = Cr^2e^{-2Zr/a_0}$, where C is a constant. Show that $P(r)$ has its maximum value at $r = a_0/Z$.

Picture the Problem This is an extreme value problem. We'll begin its solution with the radial probability distribution function, differentiate it with respect to its independent variable *r*, set this derivative equal to zero, and solve for an extreme value for *r*. We can show that this value corresponds to a maximum by evaluating the second derivative of $P(r)$ at the location found from the first derivative.

Differentiate the radial probability distribution function with respect to *r* to obtain:

$$\begin{aligned}\frac{dP(r)}{dr} &= C\frac{d}{dr}\left[r^2e^{-2Zr/a_0}\right]\\ &= C\left[2re^{-2Zr/a_0} - \frac{2Zr^2}{a_0}e^{-2Zr/a_0}\right]\\ &= \frac{2CZr}{a_0}e^{-2Zr/a_0}\left(\frac{a_0}{Z} - r\right)\\ &= 0 \text{ for extrema}\end{aligned}$$

Solve for *r* to obtain:

$$r = \frac{a_0}{Z}$$

To show that this value for r corresponds to a maximum, differentiate $dP(r)/dr$ to obtain:

$$\frac{d^2P(r)}{dr^2} = -\frac{2CZr}{a_0}e^{-2Zr/a_0} + \left(\frac{a_0}{Z} - r\right)\left(-\frac{4CZ^2}{a_0^2} + \frac{2CZ}{a_0}\right)e^{-2Zr/a_0}$$

Evaluate this derivative at $r = a_0/Z$:

$$\left.\frac{d^2P(r)}{dr^2}\right|_{r=\frac{a_0}{Z}} = -2Ce^{-2} < 0$$

because C is a positive constant. Hence, $P(r)$ has its maximum value at

$$r = \boxed{\frac{a_0}{Z}}$$

46 ••• Show that the number of states in the hydrogen atom for a given n is $2n^2$.

Picture the Problem We can double the sum of the number of m states for a given n to show that the number of states in the hydrogen atom for a given n is $2n^2$.

The number of m_ℓ states for a given n is:

$$N_{m_\ell} = \sum_{\ell=0}^{n-1}(2\ell+1) = 2\sum_{\ell=0}^{n-1}\ell + \sum_{\ell=0}^{n-1}(1)$$

The sum of all integers from 0 to p is:

$$\sum_{\ell=0}^{p}\ell = \tfrac{1}{2}p(p+1)$$

and

$$2\sum_{\ell=0}^{n-1}\ell = 2\left(\tfrac{1}{2}\right)(n-1)(n) = n^2 - n$$

The second term is:

$$\sum_{\ell=0}^{n-1}(1) = n$$

Substitute for $2\sum_{\ell=0}^{n-1}\ell$ and $\sum_{\ell=0}^{n-1}(1)$ in the expression for N_m to obtain:

$$N_{m_\ell} = n^2 - n + n = n^2$$

Because N, the number of electron states, is twice the number of m_ℓ states, the number of electron states is:

$$N = 2N_{m_\ell} = \boxed{2n^2}$$

47 ••• Calculate the probability that the electron in the ground state of a hydrogen atom is in the region $0 < r < a_0$.

Picture the Problem The ground state of a hydrogen atom is the state described by $n = 1$, $\ell = 0$, $m_\ell = 0$. We can calculate the probability that the electron in the ground state of the hydrogen atom is in the region $0 < r < a_0$ by evaluating the integral $\int_0^{a_0} 4\pi r^2 \psi_{100}^2(r)dr$.

Express the probability that the electron in the ground state of a hydrogen atom is in the region $0 < r < a_0$:

$$P(r) = \int_0^{a_0} 4\pi r^2 \psi_{100}^2(r)dr$$

Express the ground-state wave function for hydrogen:

$$\psi_{100}(r) = \frac{1}{\sqrt{\pi}}\left(\frac{1}{a_0}\right)^{3/2} e^{-r/a_0}$$

Square the wave function to obtain:

$$\psi_{100}^2(r) = \frac{1}{\pi a_0^3} e^{-2r/a_0}$$

Substitute for $\psi_{100}^2(r)$ to obtain:

$$P(r) = \int_0^{a_0} 4\pi r^2 \left(\frac{1}{\pi a_0^3} e^{-2r/a_0}\right)dr$$

$$= \frac{4}{a_0^3}\int_0^{a_0} r^2 e^{-2r/a_0}\,dr$$

Use a table of integrals to find:

$$\int x^2 e^{bx} dx = \frac{e^{bx}}{b^3}\left(b^2x^2 - 2bx + 2\right)$$

Use this integral to show that:

$$P(r) = -e^{-2r/a_0}\left(\frac{2r^2}{a_0^2} + \frac{2r}{a_0} + 1\right)\Bigg|_0^{a_0}$$

$$= 1 - 5e^{-2} = \boxed{0.323}$$

The Spin-Orbit Effect and Fine Structure

48 • The potential energy of a magnetic moment in an external magnetic field is given by $U = -\vec{\boldsymbol{\mu}} \cdot \vec{\boldsymbol{B}}$. (*a*) Calculate the difference in energy between the two possible orientations of an electron in a magnetic field $\vec{\boldsymbol{B}} = (1.50\ \text{T})\hat{\boldsymbol{k}}$. (*b*) If these electrons are bombarded with photons of energy equal to this energy difference, ″spin flip″ transitions can be induced. Find the wavelength of the photons needed for such transitions. This phenomenon is called *electron spin resonance*.

Picture the Problem The energy difference between the two possible orientations of an electron in a magnetic field is $2\mu B$ and the wavelength of the photons required to induce a spin-flip transition can be found from $hc/\Delta E$. The magnetic moment μ_B associated with the spin of an electron is 5.79×10^{-5} eV/T.

(*a*) The difference in energy between the two spin orientations is given by:

$$\Delta E = 2\mu B$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = 2\left(5.79\times10^{-5}\ \text{eV/T}\right)\left(1.50\ \text{T}\right) = 1.737\times10^{-4}\ \text{eV} = \boxed{174\ \mu\text{eV}}$$

(*b*) Relate the wavelength of the photon needed to induce such a transition to the energy required:

$$\lambda = \frac{hc}{\Delta E}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{1.737\times10^{-4}\ \text{eV}} = 7.139\times10^{6}\,\text{nm} = \boxed{7.14\,\text{mm}}$$

49 • The total angular momentum of a hydrogen atom in a certain excited state has the quantum number $j = \frac{1}{2}$. What can you say about the value of the orbital angular-momentum quantum number ℓ?

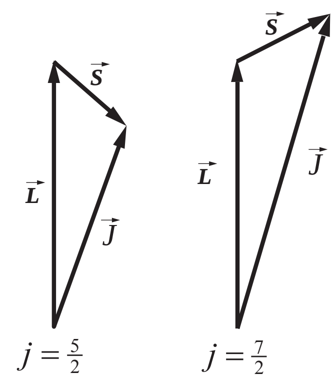
Determine the Concept j and ℓ are constrained according to $j = \ell \pm \frac{1}{2}$. For j = ½, $\ell = \frac{1}{2} \pm \frac{1}{2}$ or $\ell = \boxed{0\,\text{or}\,1}$.

50 • A hydrogen atom is in the state $n = 3$, $\ell = 2$. What are the possible values of j?

Determine the Concept j and ℓ are constrained according to $j = \ell \pm \frac{1}{2}$. For $\ell = 2$, $j = 2 \pm \frac{1}{2}$, or $j = \boxed{\frac{3}{2} \text{ or } \frac{5}{2}}$

51 • Using a scaled vector diagram, show how the orbital angular momentum $\vec{L}$ combines with the spin angular momentum $\vec{S}$ to produce the two possible values of total angular momentum $\vec{J}$ for the $\ell = 3$ state of the hydrogen atom.

Picture the Problem The total angular momentum vector $\vec{J}$ is the sum of the orbital momentum vector $\vec{L}$ and the spin orbital angular momentum vector $\vec{S}$. The quantum number j can be either $\ell + \frac{1}{2}$ or $\ell - \frac{1}{2}$, where $\ell \neq 0$. Hence, j can take on the values 3 + 1/2 = 7/2 and 3 − 1/2 = 5/2. The scaled vector diagrams are shown to the right.



The Periodic Table

52 • The total number of states of a hydrogen atom that has principal quantum number $n = 4$ is (*a*) 4, (*b*) 16, (*c*) 32, (*d*) 36, (*e*) 48.

Determine the Concept The total number of quantum states of hydrogen with quantum number n is $2n^2$. For $n = 4$, we have $2(4)^2 = 32$. $\boxed{(c)}$ is correct.

53 • How many of the eight electrons in an oxygen atom in the ground state are found in a p state? (*a*) 0, (*b*) 2, (*c*) 4, (*d*) 6, (*e*) 8

Determine the Concept From Table 36-1, oxygen's electronic configuration is $1s^22s^22p^4$. Because there are 4 electrons in the p state, $\boxed{(c)}$ is correct.

54 • Write the ground-state electron configuration of (*a*) an atom of carbon and (*b*) an atom of oxygen.

Determine the Concept We can use the atomic numbers of carbon and oxygen to determine the sum of the exponents in their electronic configurations and then use the rules for the filling of the shells to find their electronic configurations.

(*a*) The atomic number Z of carbon is 6. So we must fill the subshells of the electronic configuration until we have placed its 6 electrons. This is accomplished by writing:

$$\boxed{1s^2 2s^2 2p^2}$$

(*b*) The atomic number Z of oxygen is 8. So we must fill the subshells of the electronic configuration until we have placed its 8 electrons. This is accomplished by writing:

$$\boxed{1s^2 2s^2 2p^4}$$

55 • Give the possible values of the z component of the orbital angular momentum of (*a*) a d electron, and (*b*) an f electron.

Determine the Concept We can find the z component of the orbital angular momentum using $L_z = m_\ell \hbar$ and the relationship between the quantum numbers ℓ (which we know from the state of the electrons) and m_ℓ (which is related to ℓ through $m_\ell = -\ell, (-\ell + 1), \ldots, 0, 1, 2, \ldots \ell$).

(*a*) For a d electron $\ell = 2$. For $\ell = 2$, $m_\ell = -2, -1, 0, 1$ or 2. Because $L_z = -m_\ell\hbar, \ldots, m_\ell\hbar$:

$$L_z = \boxed{-2\hbar, -\hbar, 0, \hbar, 2\hbar}$$

(*b*) For an f electron, $\ell = 3$. For $\ell = 3$, $m_\ell = -3, -2, -1, 0, 1, 2, 3$. Because $L_z = -m_\ell\hbar, \ldots, m_\ell\hbar$:

$$L_z = \boxed{-3\hbar, -2\hbar, -\hbar, 0, \hbar, 2\hbar, 3\hbar}$$

Optical Spectra and X-Ray Spectra

56 • The optical spectra of atoms that have two electrons in the same highest energy shell are similar, but they are quite different from the spectra of atoms that have just one electron in the highest energy shell because of the interaction of the two electrons. Group the elements according to similar spectra: lithium, beryllium, sodium, magnesium, potassium, calcium, chromium, nickel, cesium, and barium.

Determine the Concept Lithium, sodium, potassium, chromium, and cesium have one outer s electron and hence belong in the same group. Beryllium, magnesium, calcium, nickel, and barium have two outer s electrons and, hence, belong in the same group.

57 • Write down the possible electron configurations for the first excited state of (*a*) a hydrogen atom, (*b*) a sodium atom, and (*c*) a helium atom.

Determine the Concept We can use Table 35-1 to find the electronic configurations for the first excited states of these atoms.

(*a*) For H, E depends only on n and the lowest excited state is: $\boxed{\text{2s or 2p}}$

(*b*) For Na, the 3p state is higher energy than the 3s state and the lowest excited state is: $\boxed{1s^2 2s^2 2p^6 3p}$

(*c*) For He, the lowest excited state has one electron in the 2s state and the lowest excited state is: $\boxed{1s2s}$

58 • Indicate which of the following atoms should have optical spectra similar to a hydrogen atom and which of the following atoms should have optical spectra similar to a helium atom: Li, Ca, Ti, Rb, Hg, Ag, Cd, Ba, Fr, and Ra.

Determine the Concept Atoms with one outer electron have spectra similar to H: Li, Rb, Ag, Fr. Atoms with two outer electrons have spectra similar to He: Ca, Ti, Hg, Cd, Ba, Ra. Therefore, the table should be completed as shown below:

Optical Spectra Similar to Hydrogen	Optical Spectra Similar to Helium
Li, Rb, Ag, Fr	Ca, Ti, Hg, Cd, Ba, Ra

59 • (*a*) Calculate the next two longest wavelengths in the K series (after the K_α line) of molybdenum. (*b*) What is the wavelength of the shortest wavelength in this series?

Picture the Problem When an electron from state n drops into a vacated state in the n = 1 shell, a photon of energy $\Delta E = E_n - E_1$ is emitted. We can find the wavelength of this photon using $\lambda = hc/\Delta E$. The second and third longest wavelengths in the K series correspond to transitions from n = 3 to n = 1 and n = 4 to n = 1 and the shortest wavelength to the transition from $n = \infty$ to n = 1.

Express the wavelength of the emitted photon in terms of the energy transition within the atom:

$$\lambda = \frac{hc}{E_n - E_1} = \frac{1240\,\text{eV}\cdot\text{nm}}{E_n - E_1}$$

Express the energy of the nth energy state:

$$E_n = -(Z-1)^2 \frac{E_0}{n^2} \text{ where } n = 1, 2, \ldots$$

Substitute to obtain:

$$\lambda = \frac{hc}{E_n - E_1}$$
$$= \frac{1240\,\text{eV}\cdot\text{nm}}{-(Z-1)^2 \frac{E_0}{n^2} - \left(-(Z-1)^2 \frac{E_0}{1^2}\right)}$$
$$= \frac{1240\,\text{eV}\cdot\text{nm}}{(Z-1)^2 E_0 \left(1 - \frac{1}{n^2}\right)}$$

(*a*) Evaluate this expression with $n = 3$ and $Z = 42$ to obtain:

$$\lambda_3 = \frac{1240\,\text{eV}\cdot\text{nm}}{(42-1)^2(13.6\,\text{eV})\left(1-\frac{1}{3^2}\right)} = \boxed{0.0610\,\text{nm}}$$

Use $n = 4$ and $Z = 42$ to obtain:

$$\lambda_4 = \frac{1240\,\text{eV}\cdot\text{nm}}{(42-1)^2(13.6\,\text{eV})\left(1-\frac{1}{4^2}\right)} = \boxed{0.0578\,\text{nm}}$$

(*b*) The shortest wavelength in the series corresponds to the largest energy difference between the initial and final states. Repeat the calculation in Part (*a*) with $n = \infty$ to obtain:

$$\lambda_\infty = \frac{1240\,\text{eV}\cdot\text{nm}}{(42-1)^2(13.6\,\text{eV})(1-0)} = \boxed{0.0542\,\text{nm}}$$

60 • The wavelength of the K_α line for a certain element is 0.3368 nm. What is the element?

Picture the Problem When an electron from state n drops into the vacated state in the $n = 1$ shell, a photon of energy $E_n - E_1$ is emitted. The wavelength of this photon is $\lambda = \frac{hc}{(Z-1)^2(13.6\,\text{eV})\left(1-\frac{1}{n^2}\right)}$. Hence, if we know the wavelength of the K_α line we can solve for the atomic number of the element and use its value to identify the element.

Express the wavelength of the K$_\alpha$ line as a function of the atomic number of the element:

$$\lambda = \frac{hc}{(Z-1)^2(13.6\,\text{eV})\left(1-\frac{1}{n^2}\right)}$$

Solving for Z gives:

$$Z = 1 + \sqrt{\frac{hc}{\lambda(13.6\,\text{eV})\left(1-\frac{1}{n^2}\right)}}$$

Substitute numerical values and evaluate Z:

$$Z = 1 + \sqrt{\frac{1240\,\text{eV}\cdot\text{nm}}{(0.3368\,\text{nm})(13.6\,\text{eV})\left(1-\frac{1}{2^2}\right)}} = 20$$

The element whose atomic number is 20 is $\boxed{\text{calcium}}$.

61 • Calculate the wavelength of the K_α line in (*a*) a magnesium ($Z = 12$) atom and (*b*) a copper ($Z = 29$) atom.

Picture the Problem The K_α corresponds to a transition from $n = 2$ to $n = 1$. Equation 36-46 relates the atomic number Z to the wavelength of the emitted photon.

From Equation 36-46 we have:

$$\lambda_{K_\alpha} = \frac{hc}{(Z-1)^2 E_0\left(1-\frac{1}{2^2}\right)}$$

(*a*) Substitute numerical values and evaluate λ_{K_α} for magnesium:

$$\lambda_{K_\alpha} = \frac{1240\,\text{eV}\cdot\text{nm}}{(12-1)^2(13.6\,\text{eV})\left(1-\frac{1}{2^2}\right)} = \boxed{1.00\,\text{nm}}$$

(*b*) Substitute numerical values and evaluate λ_{K_α} for copper:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{(29-1)^2(13.6\,\text{eV})\left(1-\frac{1}{2^2}\right)} = \boxed{0.155\,\text{nm}}$$

General Problems

62 • What is the energy of the shortest wavelength photon emitted by the hydrogen atom?

Picture the Problem The energy associated with a transition from an initial state to some final state is given by $\Delta E = E_i - E_f$ and the wavelength λ of a photon emitted in such a transition is given by $\lambda = hc/\Delta E$. Hence, the shortest wavelength corresponds to the largest energy difference.

Express the wavelength of the emitted photon in terms of the energy difference ΔE between the atom's initial and final states:

$$\lambda = \frac{hc}{\Delta E} \Rightarrow \Delta E = \frac{hc}{\lambda}$$

For λ_{min}, ΔE will be the energy required to ionize a hydrogen atom:

$$\Delta E_{max} = \frac{hc}{\lambda_{min}} = \boxed{13.6\,\text{eV}}$$

63 • The wavelength of a spectral line of hydrogen is 97.254 nm. Identify the transition that results in this line, assuming that the transition is to the ground state.

Picture the Problem This spectral line is due to a transition from some initial state n_i to a final state n_f (we're given that the final state is the ground state). The wavelength of the spectral line is related to the difference in energy ΔE between these states according to $\lambda = 1240\,\text{eV}\cdot\text{nm}/\Delta E$ and the energy of the nth state is given (for hydrogen, $Z = 1$) by $E_n = (1^2)(-13.6\text{ eV})/n^2$.

Relate the wavelength of a spectral line to the energy transition within the atom:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E} \qquad (1)$$

Express the energy difference ΔE in a transition:

$$\Delta E = E_i - E_f = -\frac{Z^2E_0}{n_i^2} + \frac{Z^2E_0}{n_f^2}$$

$$= Z^2E_0\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

For $Z = 1$ and $E_0 = 13.6$ eV:

$$\Delta E = (13.6\,\text{eV})\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

Substitute in equation (1) to obtain:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{(13.6\,\text{eV})\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)} = \frac{91.2\,\text{nm}}{\frac{1}{n_f^2} - \frac{1}{n_i^2}}$$

or

$$\frac{1}{n_f^2} - \frac{1}{n_i^2} = \frac{91.2\,\text{nm}}{\lambda}$$

For $\lambda = 97.254$ nm and $n_f = 1$ this expression simplifies to:

$$1 - \frac{1}{n_i^2} = \frac{91.2\,\text{nm}}{97.254\,\text{nm}} = 0.938$$

Solving for n_i gives:

$$n_i = 4$$

The transition that produced the given wavelength was from $\boxed{n_i = 4 \text{ to } n_f = 1}$.

64 •• The wavelength of a spectral line of hydrogen is 1093.8 nm. Identify the transition that results in this line.

Picture the Problem This spectral line is due to a transition from some initial state n_i to a final state n_f. The wavelength of the spectral line is related to the difference in energy ΔE between these states according to $\lambda = 1240\,\text{eV}\cdot\text{nm}/\Delta E$ and the energy of the nth state is given (for hydrogen, $Z = 1$) by $E_n = (1^2)(-13.6\text{ eV})/n^2$.

Relate the wavelength of a spectral line to the energy transition within the atom:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E} \qquad (1)$$

Express the energy difference ΔE in a transition:

$$\Delta E = E_i - E_f = -\frac{Z^2 E_0}{n_i^2} + \frac{Z^2 E_0}{n_f^2} = Z^2 E_0\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

For $Z = 1$ and $E_0 = 13.6$ eV:

$$\Delta E = (13.6\,\text{eV})\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

Substitute in equation (1) to obtain:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{(13.6\,\text{eV})\left(\frac{1}{n_f^2}-\frac{1}{n_i^2}\right)} = \frac{91.2\,\text{nm}}{\frac{1}{n_f^2}-\frac{1}{n_i^2}}$$

or

$$\frac{1}{n_f^2}-\frac{1}{n_i^2} = \frac{91.2\,\text{nm}}{\lambda}$$

Solving for n_f and simplifying gives :

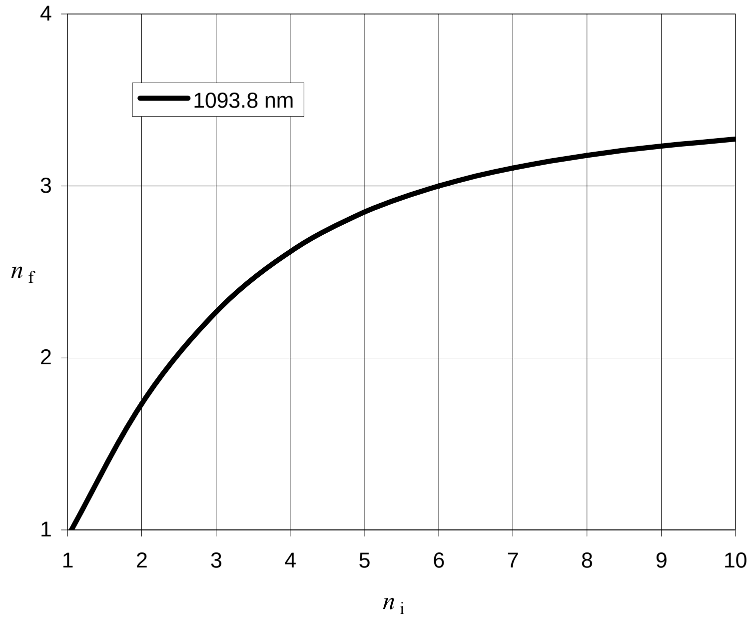
$$n_f = \frac{1}{\sqrt{\frac{91.2\text{ nm}}{\lambda}+\frac{1}{n_i^2}}}$$

Note that n_f and n_i are integers. A spreadsheet program to generate data for a graph of n_f as a function of n_i is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
B2	1093.8	λ
A5	1	n_i
B5	1/SQRT((91.2/$B$2)+(1/A5^2))	$\frac{1}{\sqrt{\frac{91.2\text{ nm}}{\lambda}+\frac{1}{n_i^2}}}$

	A	B	C
1			
2	lambda=	1093.8	nm
3			
4	*n*_i	*n*_f	
5	1	0.96	
6	2	1.73	
7	3	2.27	
8	4	2.62	
9	5	2.85	
10	**6**	**3.00**	
11	7	3.10	
12	8	3.18	
13	9	3.23	
14	10	3.27	

A graph of n_f as a function of n_i follows. Consulting either the spreadsheet table or the graph we can see that the transition that produces the given wavelength is from $\boxed{n_i = 6 \text{ to } n_f = 3}$.



65 •• Spectral lines of the following wavelengths are emitted by a singly ionized helium atom: 164 nm, 230.6 nm, and 541 nm. Identify the transitions that result in these spectral lines.

Picture the Problem These spectral lines are due to transitions in singly ionized helium from some initial state n_i to a final state n_f. The wavelengths of the spectral lines are related to the difference in energy ΔE between these states according to $\lambda = 1240\,\text{eV}\cdot\text{nm}/\Delta E$ and the energy of the nth state is given (for helium, $Z = 2$) by $E_n = (2^2)(-13.6\text{ eV})/n^2$.

Relate the wavelength of a spectral line to the energy transition within the atom:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E} \qquad (1)$$

Express the energy difference ΔE in a transition:

$$\Delta E = E_i - E_f = -\frac{Z^2E_0}{n_i^2} + \frac{Z^2E_0}{n_f^2}$$

$$= Z^2E_0\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right)$$

For $Z = 2$ and $E_0 = 13.6$ eV:

$$\Delta E = 2^2(13.6\,\text{eV})\left(\frac{1}{n_\text{f}^2}-\frac{1}{n_\text{i}^2}\right) = (54.4\,\text{eV})\left(\frac{1}{n_\text{f}^2}-\frac{1}{n_\text{i}^2}\right)$$

Substitute in equation (1) to obtain:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{(54.4\,\text{eV})\left(\frac{1}{n_\text{f}^2}-\frac{1}{n_\text{i}^2}\right)} = \frac{22.8\,\text{nm}}{\frac{1}{n_\text{f}^2}-\frac{1}{n_\text{i}^2}}$$

or

$$\frac{1}{n_\text{f}^2}-\frac{1}{n_\text{i}^2} = \frac{22.8\,\text{nm}}{\lambda}$$

Solving for n_f and simplifying gives :

$$n_\text{f} = \frac{1}{\sqrt{\frac{22.8\,\text{nm}}{\lambda}+\frac{1}{n_\text{i}^2}}}$$

Note that n_f and n_i are integers. A spreadsheet program to generate data for a graph of n_f as a function of n_i is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
B2	164	λ
C2	230.6	λ
D2	541	λ
A5	1	n_i
B5	1/SQRT((91.2/$B$2)+(1/A5^2))	$\frac{1}{\sqrt{\frac{22.8\,\text{nm}}{\lambda}+\frac{1}{n_\text{i}^2}}}$
C5	1/SQRT((91.2/$C$2)+(1/A5^2))	$\frac{1}{\sqrt{\frac{22.8\,\text{nm}}{\lambda}+\frac{1}{n_\text{i}^2}}}$
D5	1/SQRT((91.2/$D$2)+(1/A5^2))	$\frac{1}{\sqrt{\frac{22.8\,\text{nm}}{\lambda}+\frac{1}{n_\text{i}^2}}}$

	A	B	C	D	E
1					
2	lambda=	164	230.6	541	nm
3					

4	n_i	n_f	n_f	n_f

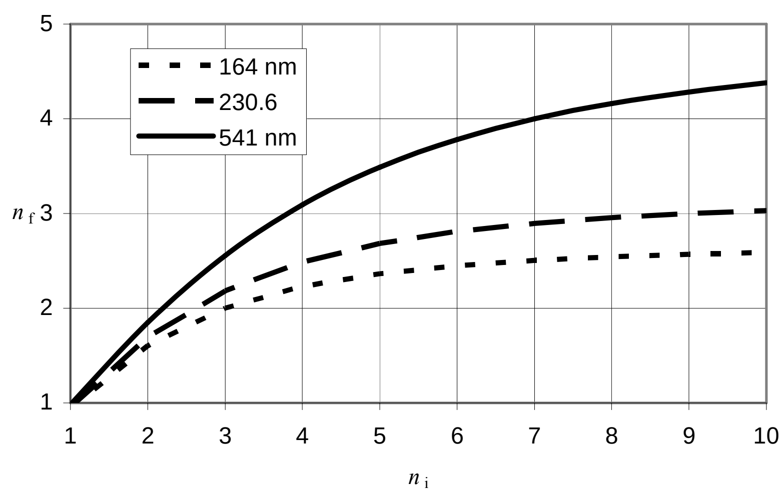
13	**9**	2.57	**3.00**	4.28	
14	10	2.59	3.03	4.38	

A graph of n_f as a function of n_i follows. Consulting either the spreadsheet table or the graph we can see that the transitions corresponding to the given wavelengths are:

λ, nm	n_i	n_f
164	3	2
230.6	9	3
541	7	4



66 •• The combination of physical constants $\alpha = e^2k/\hbar c$, where k is the Coulomb constant, is known as the *fine-structure constant*. It appears in numerous relations in atomic physics. (*a*) Show that α is dimensionless. (*b*) Show that in the Bohr model of the hydrogen atom $v_n = c\alpha/n$, where v_n is the speed of the electron in the state of quantum number n.

Picture the Problem We can show that α is dimensionless by showing that it has no units. In Part (*b*) we can use Bohr's 3rd postulate and the expression for the radii of the Bohr orbits, together with the definition of α, to show that the speed of the electron in a stationary state of quantum number *n* is related to α according to $v_n = c\alpha/n$.

(*a*) Express the units of α:

$$\frac{\mathrm{C}^2\left(\dfrac{\mathrm{N\cdot m^2}}{\mathrm{C}^2}\right)}{(\mathrm{J\cdot s})\dfrac{\mathrm{m}}{\mathrm{s}}}=\frac{\mathrm{N\cdot m^2}}{\mathrm{J\cdot m}}=1$$

Because α is unitless, it is also dimensionless.

(*b*) Apply the quantization of angular momentum postulate to obtain:

$$v_n=\frac{n\hbar}{mr_n}$$

The radii of the Bohr orbits are given by:

$$r_n=n^2\frac{\hbar^2}{mkZe^2}$$

or, because $Z = 1$ for hydrogen,

$$r_n=n^2\frac{\hbar^2}{mke^2}$$

Substitute and simplify to obtain:

$$v_n=\frac{n\hbar}{mn^2\dfrac{\hbar^2}{mke^2}}=\frac{ke^2}{n\hbar}$$

Divide this expression by the definition of α to obtain:

$$\frac{v_n}{\alpha}=\frac{\dfrac{ke^2}{n\hbar}}{\dfrac{e^2k}{\hbar c}}=\frac{c}{n}\Rightarrow v_n=\boxed{\frac{\alpha c}{n}}$$

67 •• The wavelengths of the photons emitted by a potassium atom corresponding to transitions from the $4P_{3/2}$ and $4P_{1/2}$ states to the ground state are 766.41 nm and 769.90 nm. (*a*) Calculate the energies of these photons in electron volts. (*b*) The difference in the energies of these photons equals the difference in energy ΔE between the $4P_{3/2}$ and $4P_{1/2}$ states in potassium. Calculate ΔE. (*c*) Estimate the magnetic field that the 4p electron in potassium experiences.

Picture the Problem Because the energies of the photons emitted by potassium during these transitions are related to their wavelengths through $hf = (1240\ \text{eV}\cdot\text{nm}/\lambda)$ eV where λ is in nm, we can use this relationship to find the energies of the given photons. The difference in energy between these states can be found using its definition and is related to the magnetic field through $\Delta E = 2\mu_B B$.

(*a*) For $\lambda = 766.41$ nm:

$$hf = \frac{1240\,\text{eV}\cdot\text{nm}}{766.41\,\text{nm}} = \boxed{1.6179\,\text{eV}}$$

For $\lambda = 769.90$ nm:

$$hf = \frac{1240\,\text{eV}\cdot\text{nm}}{769.90\,\text{nm}} = \boxed{1.6106\,\text{eV}}$$

(*b*) Using its definition, express the difference in energy between these two states:

$$\Delta E = 1.6179\,\text{eV} - 1.6106\,\text{eV} = \boxed{0.0073\,\text{eV}}$$

(*c*) Relate the energy difference between these states ΔE to the magnetic field B and the quantum unit of magnetic moment (a Bohr magneton) μ_B:

$$\Delta E = 2\mu_B B \Rightarrow B = \frac{\Delta E}{2\mu_B}$$

Substitute numerical values and evaluate B:

$$B = \frac{0.0073\,\text{eV}}{2\left(5.79\times10^{-5}\ \text{eV/T}\right)} = \boxed{63\,\text{T}}$$

Remarks: This magnetic field is about 42 times that of commercial magnetic resonance imagers.

68 •• To observe the characteristic *K* lines of the X-ray spectrum, one of the $n = 1$ electrons must be ejected from the atom. This is generally accomplished by bombarding the target material with electrons of sufficient energy to eject this tightly bound electron. What is the minimum energy required to observe the *K* lines of (*a*) a tungsten atom, (*b*) a molybdenum atom, and (*c*) a copper atom?

Picture the Problem One 1s electron must be released from the atom. Because the electron is shielded from the nuclear charge *Z* by one other 1s electron, the effective charge is $Z - 1$, and the ionization energy for that 1s electron is $E_{min} = (Z - 1)^2 E_0$.

(*a*) For tungsten, $Z = 74$, and:

$$E_{min} = 73^2(13.6\,\text{eV}) = \boxed{72.5\,\text{keV}}$$

(*b*) For molybdenum, $Z = 42$, and:

$$E_{\min} = 41^2(13.6\,\text{eV}) = \boxed{22.9\,\text{keV}}$$

(*c*) For copper, $Z = 29$, and:

$$E_{\min} = 28^2(13.6\,\text{eV}) = \boxed{10.7\,\text{keV}}$$

69 •• **[SSM]** We are often interested in finding the quantity ke^2/r in electron volts when r is given in nanometers. Show that $ke^2 = 1.44$ eV·nm.

Picture the Problem We can show that $ke^2 = 1.44$ eV·nm by solving the equation for the ground state energy of an atom for ke^2.

Express the ground state energy of an atom as a function of k, e, and a_0:

$$E_0 = \frac{ke^2}{2a_0} \Rightarrow ke^2 = 2E_0a_0$$

Substitute numerical values and evaluate ke^2:

$$ke^2 = 2(13.6\,\text{eV})(0.0529\,\text{nm}) = \boxed{1.44\,\text{eV}\cdot\text{nm}}$$

70 •• The *positron* is a particle that has the same mass as the electron and carries a charge equal to $+e$. *Positronium* is a bound state of an electron-positron combination. (*a*) Calculate the energies of the five lowest energy states of positronium using the reduced mass, as given in Problem 29. (*b*) Do transitions between any of the levels found in Part (*a*) fall in the visible range of wavelengths? If so, which transitions are these?

Picture the Problem We can use Problem 29 to express the energy levels of positronium in terms of the reduced mass of the electron-positron system. In Part (*b*) we can find the energies corresponding to 400 nm and 700 nm to decide whether the transitions between any of the levels found in (*a*) fall in the visible range of wavelengths

(*a*) Express the energy of positronium as a function of the quantum number n:

$$E_n = -\frac{m_rk^2e^4}{2\hbar^2}\frac{Z^2}{n^2}$$

From Problem 29 we have:

$$m_r = \frac{m_\text{e}m_\text{pos}}{m_\text{e} + m_\text{pos}}$$

Because $m_\text{e} = m_\text{pos}$:

$$m_r = \frac{m_\text{e}m_\text{e}}{m_\text{e} + m_\text{e}} = \frac{m_\text{e}}{2}$$

Substitute and simplify to obtain:

$$E_n = -\frac{m_\text{e}k^2e^4}{4\hbar^2}\frac{1}{n^2} = -\frac{E_0}{2n^2}$$

Evaluate E_n for $n = 1, 2, 3, 4$, and 5 to obtain:

n	E_n (eV)
1	−6.80
2	−1.70
3	−0.756
4	−0.425
5	−0.272

(*b*) Relate the wavelength of the emitted photons to the energy-level differences:

$$\lambda = \frac{hc}{\Delta E} = \frac{1240\ \text{eV}\cdot\text{nm}}{\Delta E}$$

Solving for ΔE yields:

$$\Delta E = \frac{1240\ \text{eV}\cdot\text{nm}}{\lambda}$$

Evaluate ΔE for $\lambda = 400$ nm and $\lambda = 700$ nm:

$$\Delta E_{400\ \text{nm}} = \frac{1240\ \text{eV}\cdot\text{nm}}{400\ \text{nm}} = 3.10\ \text{eV}$$

and

$$\Delta E_{700\ \text{nm}} = \frac{1240\ \text{eV}\cdot\text{nm}}{700\ \text{nm}} = 1.77\ \text{eV}$$

Because none of the energies in the above table are in the interval 1.77 eV to 3.10 eV, no transitions are in the visible range of wavelengths.

71 • In 1947, Lamb and Retherford showed that there is a very small energy difference between the $2S_{1/2}$ and the $2P_{1/2}$ states of the hydrogen atom. They measured this difference essentially by causing transitions between the two states using very long wavelength electromagnetic radiation. The energy difference (the Lamb shift) is 4.372×10^{-6} eV and is explained by quantum electrodynamics as being due to fluctuations in the energy level of the vacuum. (*a*) What is the frequency of a photon whose energy is equal to the Lamb shift energy? (*b*) What is the wavelength of this photon? In what spectral region does it belong?

Picture the Problem We can use $E = hf$ to find the frequency of the photon and $\lambda = hc/E$ to find its wavelength.

(*a*) The energy of the photon whose energy is equal to the Lamb shift energy is given by:

$$E = hf \Rightarrow f = \frac{E}{h}$$

Substitute numerical values and evaluate *f*:

$$f=\frac{4.372\times10^{-6}\text{ eV}}{4.136\times10^{-15}\text{ eV}\cdot\text{s}}=\boxed{1.06\,\text{GHz}}$$

(*b*) The wavelength of this photon is given by:

$$\lambda=\frac{hc}{E}$$

Substitute numerical values and evaluate λ:

$$\lambda=\frac{1240\,\text{eV}\cdot\text{nm}}{4.372\times10^{-6}\text{ eV}}=\boxed{28.4\,\text{cm}}$$

This wavelength is in the microwave portion of the electromagnetic spectrum.

72 • A Rydberg atom is one in which an electron is in a *very* high excited state ($n \approx 40$ or higher). Such atoms are useful for experiments that probe the transition from quantum-mechanical behavior to classical. Furthermore, these excited states have extremely long lifetimes (i.e., the electron will stay in this high excited state for a very long time). A hydrogen atom is in the $n = 45$ state. (*a*) What is the ionization energy of the atom when it is in this state? (*b*) What is the energy level separation (in electron volts) between this state and the $n = 44$ state? (*c*) What is the wavelength of a photon resonant with this transition between these two states? (*d*) What is the radius of the atom when it is in the $n = 45$ state?

Picture the Problem The ionization energy of the electron is the magnitude of the energy of the atom in the given state. We can use $E = -E_0/n^2$, where E_0 is the ground-state energy, to find the energy levels in the 44th and 45th states and, hence, the energy level separation between the states. The wavelength of a photon resonant with this transition can be found from $\lambda = hc/\Delta E$. We'll approximate the size of the atom in the $n = 45$ state by finding the radius of the outer-shell electron.

(*a*) The energy of the atom in its *n*th state is:

$$E_n=-\frac{E_0}{n^2}$$

The energy of the atom in the $n = 45$ state is:

$$E_{45}=-\frac{13.6\,\text{eV}}{(45)^2}=-6.72\,\text{meV}$$

The ionization energy is the negative of the energy in the state $n = 45$:

$$E_{\text{ionizing}}=-E_{45}=\boxed{6.72\,\text{meV}}$$

(*b*) The energy level separation between the $n = 45$ and $n = 44$ state is:

$$E_{45\to44}=-\left(\frac{13.6\text{ eV}}{(45)^2}-\frac{13.6\text{ eV}}{(44)^2}\right)$$
$$=3.087\times10^{-4}\text{ eV}$$
$$=\boxed{3.09\times10^{-4}\text{ eV}}$$

(*c*) The photon wavelength is:

$$\lambda = \frac{hc}{\Delta E}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\ \text{eV}\cdot\text{nm}}{3.087\times10^{-4}\ \text{eV}} = \boxed{4.02\ \text{mm}}$$

(*d*) The radii of the Bohr orbits are given by:

$$r = n^2\frac{a_0}{Z}$$

Substitute numerical values and evaluate the radius of the 45th Bohr orbit:

$$r = (45)^2\frac{0.0529\ \text{nm}}{1} = \boxed{107\ \text{nm}}$$

73 •• The deuteron, the nucleus of deuterium (heavy hydrogen), was first recognized from the spectrum of hydrogen. The deuteron has a mass that is approximately twice the mass of the proton. (*a*) Calculate the Rydberg constant for hydrogen and for deuterium using the reduced mass as given in Problem 29. (*b*) Using the result obtained in Part (*a*), determine the difference between the longest wavelength Balmer line of hydrogen protium and the longest wavelength Balmer line of deuterium.

Picture the Problem We can use the definition of the Rydberg constant and the equation for the reduced mass from Problem 29 to calculate the Rydberg constant for hydrogen and for deuterium. We can find the wavelength difference between the longest wavelength Balmer lines of hydrogen and deuterium by finding the longest wavelengths from the Rydberg-Ritz equation, using the appropriate value for R, and taking their difference.

(*a*) The Rydberg constant is given by:

$$R = \frac{m_r k^2 e^4}{4\pi c\hbar^3} = C\left(\frac{m_e}{1+\dfrac{m_e}{M}}\right)$$

where

$$C = \frac{k^2 e^4}{4\pi c\hbar^3} = 1.204662\times10^{37}\ \text{m}^{-1}/\text{kg}$$

For H:

$$R_H = C\left(\frac{m_e}{1+\dfrac{m_e}{m_p}}\right)$$

Substitute numerical values and evaluate R_H:

$$R_{\mathrm{H}} = \left(1.204662\times10^{37}\ \mathrm{m^{-1}/kg}\right)\times\left(\frac{9.109390\times10^{-31}\ \mathrm{kg}}{1+\dfrac{9.109390\times10^{-31}\ \mathrm{kg}}{1.672623\times10^{-27}\ \mathrm{kg}}}\right) = \boxed{1.096776\times10^{7}\ \mathrm{m^{-1}}}$$

For deuterium:

$$R_{\mathrm{D}} = C\left(\frac{m_{\mathrm{e}}}{1+\dfrac{m_{\mathrm{e}}}{2m_{\mathrm{p}}}}\right)$$

Substitute numerical values and evaluate R_D:

$$R_{\mathrm{D}} = \left(1.204662\times10^{37}\ \mathrm{m^{-1}/kg}\right)\left(\frac{9.109390\times10^{-31}\ \mathrm{kg}}{1+\dfrac{9.109390\times10^{-31}\ \mathrm{kg}}{2\left(1.672623\times10^{-27}\ \mathrm{kg}\right)}}\right) = \boxed{1.097075\times10^{7}\ \mathrm{m^{-1}}}$$

(*b*) Express the wavelength difference between the longest wavelength Balmer lines of hydrogen and deuterium:

$$\Delta\lambda = \lambda_{\text{longest, H}} - \lambda_{\text{longest, D}}$$

Use the Rydberg-Ritz formula to express the reciprocal wavelength:

$$\frac{1}{\lambda} = R\left(\frac{1}{n_2^2}-\frac{1}{n_1^2}\right)$$

where n_1 and n_2 are integers and $n_1 > n_2$.

Solve for λ to obtain:

$$\lambda = \frac{n_1^2 n_2^2}{R\left(n_1^2-n_2^2\right)}$$

The longest wavelength in the Balmer series corresponds to a transition from $n_1 = 3$ to $n_2 = 2$. Use $R = R_H$ to evaluate $\lambda_{\text{longest, H}}$:

$$\lambda_{\text{longest, H}} = \frac{3^2\left(2^2\right)}{\left(1.096776\times10^{7}\ \mathrm{m^{-1}}\right)\left(3^2-2^2\right)} = 656.470\ \mathrm{nm}$$

Find $\lambda_{\text{longest,D}}$ using $R = R_{\text{D}}$:

$$\lambda_{\text{longest, D}} = \frac{3^2(2^2)}{(1.097075\times10^7\ \text{m}^{-1})(3^2-2^2)} = 656.291\,\text{nm}$$

Substitute numerical values and evaluate $\Delta\lambda$:

$$\Delta\lambda = 656.470\,\text{nm} - 656.291\,\text{nm} = \boxed{0.179\,\text{nm}}$$

74 •• The muonium atom is a hydrogen atom that has the electron replaced by a μ^- particle. The μ^- has a mass 207 times as great as the electron. (*a*) Calculate the energies of the five lowest energy levels of muonium using the reduced mass as given in Problem 29. (*b*) Do transitions between any of the levels found in Part (*a*) fall in the visible range of wavelengths, (for example, between λ = 700 nm and 400 nm)? If so, which transitions are these?

Picture the Problem We can use Problem 29 to express the energy levels of muonium in terms of the reduced mass of the muonium-proton system. In Part (*b*) we can find the energies corresponding to 400 nm and 700 nm to decide whether the transitions between any of the levels found in Part (*a*) fall in the visible range of wavelengths

(*a*) Express the energy of muonium as a function of the quantum number *n*:

$$E_n = -\frac{m_r k^2 e^4}{2\hbar^2}\frac{Z^2}{n^2} \qquad (1)$$

The reduced mass m_r is given by:

$$m_r = \frac{m_{\text{p}} m_{\mu^-}}{m_{\text{p}} + m_{\mu^-}}$$

Because $m_{\mu^-} = 207 m_{\text{e}}$:

$$m_r = \frac{207 m_{\text{p}} m_{\text{e}}}{m_{\text{p}} + 207 m_{\text{e}}} = \frac{207 m_{\text{e}}}{1 + 207\dfrac{m_{\text{e}}}{m_{\text{p}}}}$$

Because $m_{\text{p}} = 1836 m_{\text{e}}$:

$$m_r = \frac{207 m_{\text{e}}}{1 + \dfrac{207}{1836}} = 186 m_{\text{e}}$$

Substitute in equation (1) and simplify to obtain:

$$E_n = -\frac{186 m_{\text{e}} k^2 e^4}{2\hbar^2}\frac{1}{n^2} = -\frac{186 E_0}{n^2}$$

Evaluate E_n for n = 1, 2, 3, 4, and 5 to obtain:

n	E_n
	(keV)
1	−2.53
2	−0.633
3	−0.281
4	−0.158
5	−0.101

(*b*) Relate the wavelength of the emitted photons to the energy-level differences:

$$\lambda = \frac{hc}{\Delta E} = \frac{1240\,\text{eV}\cdot\text{nm}}{\Delta E}$$

Solving for ΔE yields:

$$\Delta E = \frac{1240\,\text{eV}\cdot\text{nm}}{\lambda}$$

Evaluate ΔE for λ = 400 nm and λ = 700 nm:

$$\Delta E_{400\,\text{nm}} = \frac{1240\,\text{eV}\cdot\text{nm}}{400\,\text{nm}} = 3.10\,\text{eV}$$

and

$$\Delta E_{700\,\text{nm}} = \frac{1240\,\text{eV}\cdot\text{nm}}{700\,\text{nm}} = 1.77\,\text{eV}$$

Because none of the energies in the table shown above are in the interval 1.77 eV to 3.10 eV, no transitions are in the visible range of wavelengths.

75 •• The triton, a nucleus consisting of a proton and two neutrons, is unstable and has a half-life of approximately 12 years. Tritium is an atom consisting of an electron and a triton. (*a*) Calculate the Rydberg constant of tritium using the reduced mass as given in Problem 29. (*b*) Determine the difference between the longest wavelength of the Balmer lines of tritium and the longest wavelengths of the Balmer lines of deuterium (see Problem 75). In addition, (*c*) determine the difference between the longest wavelength of the Balmer lines of tritium and the longest wavelengths of the Balmer lines of hydrogen protium.

Picture the Problem We can use the definition of the Rydberg constant and the equation for the reduced mass from Problem 29 to calculate the Rydberg constant for hydrogen, tritium, and deuterium. We can find the wavelength difference between the longest wavelength Balmer lines of tritium and deuterium and tritium and hydrogen by finding the longest wavelengths from the Rydberg-Ritz equation, using the appropriate value for R, and taking their difference.

(*a*) From Problem 29 we have:

$$R = \frac{m_r k^2 e^4}{4\pi c\hbar^3} = C\left(\frac{m_e}{1+\frac{m_e}{M}}\right)$$

where

$$C = \frac{k^2 e^4}{4\pi c\hbar^3} = 1.204662\times10^{37}\ \mathrm{m^{-1}/kg}$$

For tritium:

$$R_T = C\left(\frac{m_e}{1+\frac{m_e}{m_p+2m_n}}\right)$$

Substitute numerical values and evaluate R_T:

$$R_T = \left(1.204662\times10^{37}\ \mathrm{m^{-1}/kg}\right)\left(\frac{9.109382\times10^{-31}\ \mathrm{kg}}{1+\frac{9.109382\times10^{-31}\ \mathrm{kg}}{1.672622\times10^{-27}\ \mathrm{kg}+2\left(1.674927\times10^{-27}\ \mathrm{kg}\right)}}\right)$$

$$= \boxed{1.097174\times10^{7}\ \mathrm{m^{-1}}}$$

(*b*) Express the wavelength difference between the longest wavelength Balmer lines of hydrogen and deuterium:

$$\Delta\lambda = \lambda_{\mathrm{longest,\,D}} - \lambda_{\mathrm{longest,\,T}}$$

Use the Rydberg-Ritz formula to express the reciprocal wavelength:

$$\frac{1}{\lambda} = R\left(\frac{1}{n_2^2} - \frac{1}{n_1^2}\right)$$

where n_1 and n_2 are integers and $n_1 > n_2$.

Solve for λ to obtain:

$$\lambda = \frac{n_1^2 n_2^2}{R\left(n_1^2 - n_2^2\right)}$$

The longest wavelength in the Balmer series corresponds to a transition from $n_1 = 3$ to $n_2 = 2$. Use $R = R_T$ to evaluate $\lambda_{\mathrm{longest,\,T}}$:

$$\lambda_{\mathrm{longest,\,T}} = \frac{3^2\left(2^2\right)}{\left(1.097174\times10^{7}\ \mathrm{m^{-1}}\right)\left(3^2 - 2^2\right)}$$

$$= 656.231\,\mathrm{nm}$$

For deuterium:

$$R_D = C\left(\frac{m_e}{1+\frac{m_e}{2m_p}}\right)$$

Substitute numerical values and evaluate R_D:

$$R_D = \left(1.204662\times10^{37}\ \text{m}^{-1}/\text{kg}\right)\left(\frac{9.109382\times10^{-31}\ \text{kg}}{1+\frac{9.109382\times10^{-31}\ \text{kg}}{2\left(1.672623\times10^{-27}\ \text{kg}\right)}}\right)$$
$$= 1.097075\times10^{7}\ \text{m}^{-1}$$

Find $\lambda_{\text{longest,D}}$ using $R = R_D$:

$$\lambda_{\text{longest, D}} = \frac{3^2\left(2^2\right)}{\left(1.097075\times10^{7}\ \text{m}^{-1}\right)\left(3^2-2^2\right)}$$
$$= 656.291\,\text{nm}$$

Substitute numerical values and evaluate $\Delta\lambda$:

$$\Delta\lambda = 656.291\,\text{nm} - 656.231\,\text{nm}$$
$$= \boxed{0.0600\,\text{nm}}$$

(*c*) Proceed similarly to show that for tritium and hydrogen protium:

$$\Delta\lambda = 656.4695\,\text{nm} - 656.2314\,\text{nm}$$
$$= \boxed{0.238\,\text{nm}}$$

Chapter 37
Molecules

Conceptual Problems

1 • [SSM] Would you expect NaCl to be polar or nonpolar?

Determine the Concept Yes. Because the center of charge of the positive Na ion does not coincide with the center of charge for the negative Cl ion, the NaCl molecule has a permanent dipole moment. Hence, it is a polar molecule.

2 • Would you expect N_2 to be polar or nonpolar?

Determine the Concept Because a N_2 molecule has no permanent dipole moment, it is a non-polar molecule.

3 • Does neon naturally occur as Ne or Ne_2? Explain your answer.

Determine the Concept No. Neon naturally occurs as Ne, not Ne_2. Neon is a rare gas atom with a closed shell electron configuration.

4 • What type of bonding mechanism would you expect for atoms of (*a*) HF, (*b*) KBr, (*c*) N_2, (*d*) Ag in solid silver?

Determine the Concept

(*a*) Because an electron is transferred from the H atom to the F atom, the bonding mechanism is ionic.

(*b*) Because an electron is transferred from the K atom to the Br atom, the bonding mechanism is ionic.

(*c*) Because the atoms share two electrons, the bonding mechanism is covalent.

(*d*) Because each valence electron is shared by many atoms, the bonding mechanism is metallic bonding.

5 •• [SSM] The elements on the far right column of the periodic table are sometimes called noble gases, both because they are gasses under a wide range of conditions, and because atoms of these elements almost never react with other atoms to form molecules or ionic compounds. However, atoms of noble gases can react if the resulting molecule is formed in an electronic excited state. An example is ArF. When it is formed in the excited state, it is written ArF* and is called an excimer (for <u>ex</u>cited di<u>mer</u>). Refer to Figure 37-13 and discuss how a

diagram for the electronic, vibrational, and rotation energy levels of ArF and ArF* would look in which the ArF ground state is unstable and the ArF* excited state is stable. *Remark: Excimers are used in certain kinds of lasers*.

Determine the Concept The diagram would consist of a non-bonding ground state with no vibrational or rotational states for ArF (similar to the upper curve in Figure 37-4) but for ArF* there should be a bonding excited state with a definite minimum with respect to inter-nuclear separation and several vibrational states as in the excited state curve of Figure 37-13.

6 • Find other atoms that have the same subshell electron configurations in their two highest energy orbitals as carbon atoms do. Would you expect the same type of hybridization for these orbitals as for carbon?

Determine the Concept Elements similar to carbon in outer shell configurations are silicon, germanium, tin, and lead. We would expect the same hybridization for these as for carbon, and this is indeed the case for silicon and germanium whose crystal structure is the diamond structure. Tin and lead, however, are metallic and here the metallic bond is dominant.

7 • How does the value of the effective force constant calculated for a CO molecule in Example 37-4 compare with the value of the force constant of the suspension springs on a typical automobile, which is about 1.5 kN/m?

Determine the Concept The effective force constant from Example 37-4 is 1.85×10^{3} N/m. This value is about 25% larger than the given value of the force constant of the suspension springs on a typical automobile.

8 • Explain why the moment of inertia of a diatomic molecule increases slightly with increasing angular momentum.

Determine the Concept As the angular momentum increases, the separation between the nuclei also increases (the effective force between the nuclei is similar to that of a stiff spring). Consequently, the moment of inertia also increases.

9 • Why would you expect the separation distance between the two protons to be larger in a H_2^+ ion than in a H_2 molecule?

Determine the Concept For H_2, the concentration of negative charge between the two protons holds the protons together. In a H_2^+ ion, there is only one electron that is shared by the two positive charges such that most of the electronic charge is again between the two protons. However, the negative charge in a H_2^+ ion is not as effective as the larger charge in a H_2 molecule, and the protons should be

farther apart. The experimental values support this argument. For H_2, r_0 = 0.074 nm, while for H_2^+, r_0 = 0.106 nm.

10 • At room temperature an atom typically absorb radiation only from the ground state, whereas a diatomic molecule typically absorbs radiation from many different rotational states. Why?

Determine the Concept The energy of the first excited state of an atom is orders of magnitude greater than kT at ordinary temperatures. Consequently, practically all atoms are in the ground state. By contrast, the energy separation between the ground rotational state and nearby higher rotational states is less than or roughly equal to kT at ordinary temperatures, and so these higher states are thermally excited and occupied.

11 •• The vibrational energy levels of diatomic molecules are described by a single vibrational frequency f that is the frequency of vibration of the two atoms of the molecule along the line through their centers. Would you expect to see one, or more than one, vibrational frequency in molecules that have three or more atoms? Consider in particular a water molecule H_2O (Figure 37-9).

Determine the Concept With more than two atoms in the molecule there will be more than just one frequency of vibration because there are more possible relative motions. In advanced mechanics these are known as normal modes of vibration.

Estimation and Approximation

12 •• The potential energy for a diatomic molecule has a minimum as shown in Figure 37-13. Near this minimum, the graph for the energy as a function of distance between the atoms may be approximated as a parabola, leading to the harmonic oscillator model for the vibrating molecule. An improved approximation is called the anharmonic oscillator and leads to a modification of the expression for the energy $E_\nu = \left(\nu + \frac{1}{2}\right)hf$, where ν = 0, 1, 2, …(Equation 37-18). The modified expression for energy is $E_\nu = \left(\nu + \frac{1}{2}\right)hf - \left(\nu + \frac{1}{2}\right)^2 hf\alpha$, where ν = 0, 1, 2, …. For a O_2 molecule, the constants have the values $f = 4.74 \times 10^{13}\ \text{s}^{-1}$ and $\alpha = 7.6 \times 10^{-3}$. Use this formula to estimate the smallest value of the quantum number ν for which the modified expression differs from the original expression by 10 percent.

Picture the Problem We can estimate the value of the quantum number ν for which the improved formula corrects the original formula by 10 percent by setting the ratio of the correction term to the first term equal to 10 percent and solving for ν.

Express the ratio of the correction term to the first term of the expression for E_ν and simplify to obtain:

$$\frac{\left(\nu+\frac{1}{2}\right)^2 hf\alpha}{\left(\nu+\frac{1}{2}\right)hf}=\left(\nu+\tfrac{1}{2}\right)\alpha$$

For a correction of 10 percent:

$$\left(\nu+\tfrac{1}{2}\right)\alpha=0.10\Rightarrow\nu=\frac{1}{10\alpha}-\frac{1}{2}$$

Substitute numerical values and evaluate ν:

$$\nu=\frac{1}{10\left(7.6\times10^{-3}\right)}-\frac{1}{2}=12.7\approx\boxed{13}$$

13 •• To understand why quantum mechanics is not needed to describe many macroscopic systems, estimate the rotational energy quantum number ℓ and spacing between adjacent energy levels for a baseball (m ~ 300 g, r ~ 3 cm) spinning about its own axis at 20 rev/min. *Hint: Pick* ℓ *so the quantum energy formula* $E_\ell=\ell(\ell+1)\hbar^2/(2I)$ *, where* ℓ = 0, 1, 2, ..., *(Equation 37-12) gives the correct energy for the given system. Then find the energy increase for the next highest energy level.*

Picture the Problem We can solve Equation 37-12 for ℓ and substitute for the moment of inertia and rotational kinetic energy of the baseball to estimate the quantum number ℓ and spacing between adjacent energy levels for a baseball spinning about its own axis.

The rotational energy levels are given by Equation 37-12:

$$E_\ell=\frac{\ell(\ell+1)\hbar^2}{2I}$$

where ℓ = 0, 1, 2, … is the rotational energy quantum number and I is the moment of inertia of the ball.

Solving for $\ell(\ell+1)$ yields:

$$\ell(\ell+1)=\frac{2IE_\ell}{\hbar^2}$$

Factoring ℓ from the parentheses gives:

$$\ell^2\left(1+\frac{1}{\ell}\right)=\frac{2IE_\ell}{\hbar^2}$$

The result of our calculation of ℓ will show that ℓ >> 1. Assuming for the moment that this is the case:

$$\ell^2\approx\frac{2IE_\ell}{\hbar^2}\Rightarrow\ell\approx\sqrt{\frac{2IE_\ell}{\hbar^2}}$$

Because the energy of the ball is rotational kinetic energy:

$$E_\ell=K_{\text{rot}}=\tfrac{1}{2}I\omega^2$$

Substitute for E_ℓ in the expression for ℓ and simplify to obtain:

$$\ell \approx \frac{\sqrt{2I\left(\frac{1}{2}I\omega^2\right)}}{\hbar} = \frac{\sqrt{\left(I^2\omega^2\right)}}{\hbar} = \frac{I\omega}{\hbar}$$

The moment of inertia of a ball about an axis through its diameter is (see Table 9-1):

$$I = \tfrac{2}{5}mr^2$$

Substituting for I gives:

$$\ell \approx \frac{2mr^2\omega}{5\hbar}$$

Substitute numerical values and evaluate ℓ:

$$\ell \approx \frac{2(0.300\,\text{kg})(3\,\text{cm})^2\left(\frac{20\,\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)}{5\left(1.055\times10^{-34}\,\text{J}\cdot\text{s}\right)} \approx \boxed{2\times10^{30}}$$

Set $\ell = 0$ to express the spacing between adjacent energy levels:

$$E_{0\text{r}} = \frac{\hbar^2}{2I} = \frac{5\hbar^2}{4mr^2}$$

Substitute numerical values and evaluate $E_{0\text{r}}$:

$$E_{0\text{r}} = \frac{5\left(1.055\times10^{-34}\,\text{J}\cdot\text{s}\right)^2}{4(300\,\text{g})(3.0\,\text{cm})^2} \approx \boxed{5\times10^{-65}\,\text{J}}$$

Remarks: Note that our value for ℓ justifies our assumption that ℓ >> 1.

14 •• Estimate the quantum number ν and spacing between adjacent energy levels for a 1.0-kg mass attached to spring. The spring has a force constant equal to 1200-N/m and the mass-spring system is vibrating with an amplitude of 3.0 cm. *Hint: Pick ν so that the quantum energy formula* $E_\nu = \left(\nu + \frac{1}{2}\right)hf$, *where* $\nu = 0, 1, 2, \ldots$ *(Equation 37-18) gives the correct energy for the given system. Then find the energy increase for the next highest energy level.*

Picture the Problem We can solve Equation 37-18 for ν and substitute for the frequency of the mass-and-spring oscillator to estimate the quantum number ν and spacing between adjacent energy levels for this system.

The vibrational energy levels are given by Equation 37-18:

$$E_\nu = \left(\nu + \tfrac{1}{2}\right)hf$$

where $\nu = 0, 1, 2, \ldots$

Solve for ν to obtain:

$$\nu = \frac{E_\nu}{hf} - \frac{1}{2}$$

or, because $\nu >> 1$,

$$\nu \approx \frac{E_\nu}{hf}$$

The vibrational energy of the object attached to the spring is:

$$E_\nu = \tfrac{1}{2}kA^2$$

where A is the amplitude of its motion.

Substitute for E_ν in the expression for ν to obtain:

$$\nu = \frac{kA^2}{2hf}$$

The frequency of oscillation f of the mass-and-spring oscillator is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

Substitute for f in the expression for ν and simplify to obtain:

$$\nu = \frac{\pi kA^2}{h}\sqrt{\frac{m}{k}} = \frac{\pi A^2}{h}\sqrt{mk}$$

Substitute numerical values and evaluate ν:

$$\nu = \frac{\pi(3.0\,\text{cm})^2}{6.626\times10^{-34}\ \text{J}\cdot\text{s}}\sqrt{(1.0\,\text{kg})(1200\,\text{N/m})} \approx \boxed{1\times10^{32}}$$

Set $\nu = 0$ in Equation 37-18 to express the spacing between adjacent energy levels:

$$E_{0\nu} = \frac{1}{2}hf = \frac{h}{4\pi}\sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate $E_{0\nu}$:

$$E_{0\nu} = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{4\pi}\sqrt{\frac{1200\,\text{N/m}}{1.0\,\text{kg}}} = \boxed{1.8\times10^{-33}\ \text{J}}$$

Remarks: Note that our value for ν justifies our assumption that $\nu >> 1$.

Molecular Bonding

15 • Calculate the separation of of Na^+ and Cl^- ions for which the potential energy of a single ionic unit (one Na^+ ion and one Cl^- ion) is –1.52 eV.

Picture the Problem The electrostatic potential energy with U_e with ions separated a distance r is given by $U = -ke^2/r$.

Relate the electrostatic potential energy of the ions to their separation:

$$U_e = -\frac{ke^2}{r} \Rightarrow r = -\frac{ke^2}{U_e}$$

Substitute numerical values and evaluate r:

$$r = -\frac{\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.602\times10^{-19}\ \text{C}\right)^2}{\left(-1.52\,\text{eV}\right)\left(1.602\times10^{-19}\ \frac{\text{J}}{\text{eV}}\right)} = \boxed{0.947\,\text{nm}}$$

16 • The equilibrium separation of the atoms in a HF molecule is 0.0917 nm and the measured electric dipole moment of the molecule is 6.40×10^{-30} C·m. What percentage of the HF bond is ionic?

Picture the Problem The percentage of the bonding that is ionic is given by $100\left(p_{\text{meas}}/p_{100}\right)$.

Express the percentage of the bonding that is ionic:

$$\text{Percent}_{\text{ ionic bonding}} = 100\left(\frac{p_{\text{meas}}}{p_{100}}\right)$$

Express the dipole moment for 100% ionic bonding:

$$p_{100} = er$$

Substituting for p_{100} gives:

$$\text{Percent}_{\text{ ionic bonding}} = 100\left(\frac{p_{\text{meas}}}{er}\right)$$

Substitute numerical values and evaluate the percent ionic bonding:

$$\text{Percent}_{\text{ ionic bonding}} = 100\left[\frac{6.40\times10^{-30}\ \text{C}\cdot\text{m}}{\left(1.602\times10^{-19}\ \text{C}\right)\left(0.0917\,\text{nm}\right)}\right] = \boxed{43.6\%}$$

17 •• The dissociation energy of RbF is 5.12 eV, and the equilibrium separation of RbF is 0.227 nm. The electron affinity of a fluorine atom is –3.40 eV and the ionization energy of rubidium is 4.18 eV. Determine the core-repulsion energy of RbF.

Picture the Problem If we choose the potential energy at infinity to be ΔE, the total potential energy is $U_{tot} = U_e + \Delta E + U_{rep}$, where U_{rep} is the energy of repulsion, which is found by setting the dissociation energy equal to $-U_{tot}$.

Express the total potential energy of the molecule:

$$U_{tot} = U_e + \Delta E + U_{rep}$$

The core-repulsive energy is :

$$U_{rep} = -(\Delta E + U_e + E_d) \qquad (1)$$

Calculate the energy ΔE needed to form Rb^+ and F^- ions from neutral rubidium and fluorine atoms:

$$\Delta E = 4.18\,\text{eV} - 3.40\,\text{eV} = 0.78\,\text{eV}$$

The electrostatic potential energy is given by:

$$U_e = -\frac{ke^2}{r}$$

Substitute numerical values and evaluate U_e:

$$U_e = -\frac{\left(8.988\times10^9\ \frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)(1.602\times10^{-19}\ \text{C})^2}{(0.227\,\text{nm})\left(1.602\times10^{-19}\ \frac{\text{J}}{\text{eV}}\right)} = -6.34\,\text{eV}$$

Substitute numerical values in equation (1) and evaluate U_{rep}:

$$U_{rep} = -(0.78\,\text{eV} - 6.34\,\text{eV} + 5.12\,\text{eV}) = \boxed{0.44\,\text{eV}}$$

18 •• The equilibrium separation of the K^+ and Cl^- ions in KCl is about 0.267 nm. (*a*) Calculate the potential energy of attraction of the ions. Assume that the ions are point charges at this separation. (*b*) The ionization energy of potassium is 4.34 eV and the electron affinity of chlorine is –3.62 eV. Calculate a value for the dissociation energy under the assumption that the energy of repulsion is negligible. (See Figure 37-1) (*c*) The measured dissociation energy is 4.49 eV. What is the energy due to repulsion of the ions at the equilibrium separation?

Picture the Problem The potential energy of attraction of the ions is $U_e = -ke^2/r$. We can find the dissociation energy from the negative of the sum of the potential energy of attraction and the difference between the ionization energy of potassium and the electron affinity of chlorine.

(a) The potential energy of attraction of the ions is given by:

$$U_e = -\frac{ke^2}{r}$$

where $ke^2 = 1.44$ eV·nm

Substitute numerical values and evaluate U_e:

$$U_e = -\frac{1.44\,\text{eV}\cdot\text{nm}}{0.267\,\text{nm}} = \boxed{-5.39\,\text{eV}}$$

(b) Express the total potential energy of the molecule:

$$U_{tot} = U_e + \Delta E + U_{rep}$$

or, neglecting any energy of repulsion,

$$U_{tot} = U_e + \Delta E$$

The dissociation energy is the negative of the total potential energy:

$$E_{d,calc} = -U_{tot} = -(U_e + \Delta E)$$

ΔE is the difference between the ionization energy of potassium and the electron affinity of Cl:

$$\Delta E = 4.34\,\text{eV} - 3.62\,\text{eV} = 0.72\,\text{eV}$$

Substitute numerical values and evaluate $E_{d,calc}$:

$$E_{d,calc} = -(-5.39\,\text{eV} + 0.72\,\text{eV}) = \boxed{4.67\,\text{eV}}$$

(c) The energy due to repulsion of the ions at equilibrium separation is given by:

$$U_{rep} = E_{d,calc} - E_{d,meas}$$

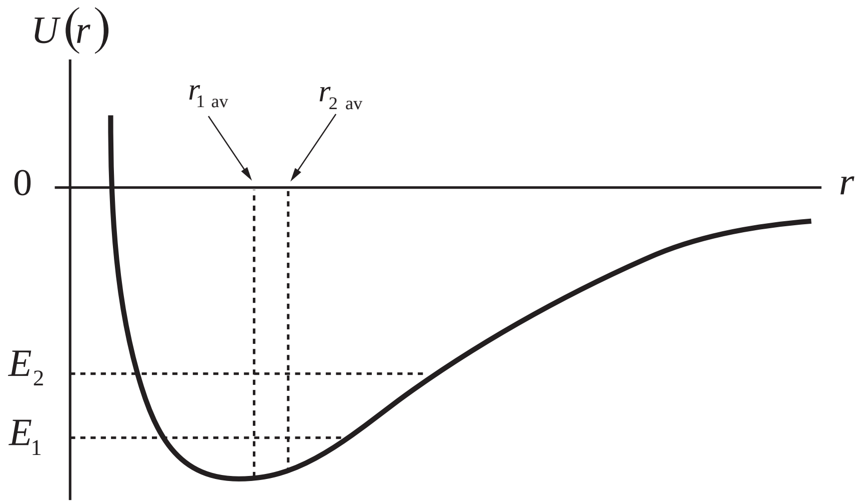
Substitute numerical values and evaluate U_{rep}:

$$U_{rep} = 4.67\,\text{eV} - 4.49\,\text{eV} = \boxed{0.18\,\text{eV}}$$

19 •• Indicate an approximate value for the average value of the separation distance r for two vibrational levels on the potential energy curve for a diatomic molecule (one of the curves in Figure 37-13). Your teacher claims that the increase in r_{av} with increases in vibration energy explains why solids expand when heated. Do you agree? If so, give an argument supporting this claim. If not, give an argument opposing this claim.

Picture the Problem You should agree. The potential energy curve is shown in the following diagram. The turning points for vibrations of energy E_1 and E_2 are at the values of r where the energies equal $U(r)$. The average value of r for the vibrational levels E_1 and E_2 are labeled $r_{1\,av}$ and $r_{2\,av}$. Note that the estimate of $r_{1\,av}$ is midway between $r_{1\,min}$ and $r_{1\,max}$. The potential is like a special spring that has a

greater spring constant for compressions than it has for extensions. The period of a spring-and-mass oscillator is inversely proportional to the square root of the spring constant, so our ″special spring″ spends more time in extension than in compression. As a result, $r_{1\,\text{av}}$ will be greater than the equilibrium radius.



This argument can be extended to explain why $r_{2\,\text{av}}$ is greater than $r_{1\text{av}}$. It is because the ″spring constant″ for extension, which can be estimated by taking the average slope of the potential energy curve in the region to the right of the equilibrium position, is greater for $E = E_2$ than for $E = E_1$. It is also because the ″spring constant″ for compression is greater for $E = E_2$ than for $E = E_1$. It follows that $r_{2\,\text{av}}$ is greater than $r_{1\,\text{av}}$. Because $r_{2,\text{av}}$ is greater than $r_{1\,\text{av}}$, it follows that as the vibrational energy of a diatomic molecule increases, the average separation of the atoms of the molecule increases and, hence, the solid expands with heating.

20 •• Calculate the potential energy of attraction between the Na^+ and Cl^- ions at the equilibrium separation $r_0 = 0.236$ nm. Compare this result with the dissociation energy given in Figure 37-1. What is the energy due to repulsion of the ions at the equilibrium separation?

Picture the Problem We can use $U_\text{e} = -ke^2/r_0$ to calculate the potential energy of attraction between the Na^+ and Cl^- ions at the equilibrium separation $r_0 = 0.236$ nm. We can find the energy due to repulsion of the ions at the equilibrium separation from $U_\text{rep} = -(U_\text{e} + E_\text{d} + \Delta E)$.

The potential energy of attraction between the Na^+ and Cl^- ions at the equilibrium separation r_0 is given by:

$$U_\text{e} = -\frac{ke^2}{r_0}$$

where $ke^2 = 1.44$ eV·nm.

Substitute numerical values and evaluate U_e:

$$U_e = -\frac{1.44\,\text{eV}\cdot\text{nm}}{0.236\,\text{nm}} = \boxed{-6.10\,\text{eV}}$$

From Figure 37-1:

$$E_d = 4.27\,\text{eV}$$

The ratio of the magnitude of the potential energy of attraction to the dissociation energy is:

$$\frac{|U_e|}{E_d} = \frac{6.10\,\text{eV}}{4.27\,\text{eV}} = \boxed{1.43}$$

U_{rep} is related to U_e, E_d, and ΔE according to:

$$U_{rep} = -(U_e + E_d + \Delta E)$$

From Figure 37-1:

$$\Delta E = 1.52\,\text{eV}$$

Substitute numerical values and evaluate U_{rep}:

$$U_{rep} = -(-6.10\,\text{eV} + 4.27\,\text{eV} + 1.52\,\text{eV}) = \boxed{0.31\text{eV}}$$

21 •• The equilibrium separation of the K^+ and F^- ions in KF is about 0.217 nm. (*a*) Calculate the potential energy of attraction of these ions. Assume that the ions are point charges at this separation. (*b*) The ionization energy of potassium is 4.34 eV and the electron affinity of fluorine is –3.40 eV. Find the dissociation energy by neglecting any energy of repulsion. (*c*) The measured dissociation energy is 5.07 eV. Calculate the energy due to repulsion of the ions at the equilibrium separation.

Picture the Problem The potential energy of attraction of the ions is $U_e = -ke^2/r$. We can find the dissociation energy from the negative of the sum of the potential energy of attraction and the difference between the ionization energy of potassium and the electron affinity of fluorine.

(*a*) The potential energy of attraction between the K^+ and F^- ions at the equilibrium separation r_0 is given by:

$$U_e = -\frac{ke^2}{r_0}$$

where ke^2 = 1.44 eV·nm.

Substitute numerical values and evaluate U_e:

$$U_e = -\frac{1.44\,\text{eV}\cdot\text{nm}}{0.217\,\text{nm}} = \boxed{-6.64\,\text{eV}}$$

(*b*) Express the total potential energy of the molecule:

$$U_{\text{tot}} = U_{\text{e}} + \Delta E + U_{\text{rep}}$$

or, neglecting any energy of repulsion,

$$U_{\text{tot}} = U_{\text{e}} + \Delta E$$

The dissociation energy is the negative of the total potential energy:

$$E_{\text{d,calc}} = -U_{\text{tot}} = -\left(U_{\text{e}} + \Delta E\right)$$

ΔE is the difference between the ionization energy of potassium and the electron affinity of fluorine:

$$\Delta E = 4.34\,\text{eV} - 3.40\,\text{eV} = 0.94\,\text{eV}$$

Substitute numerical values and evaluate $E_{\text{d,calc}}$:

$$E_{\text{d,calc}} = -\left(-6.64\,\text{eV} + 0.94\,\text{eV}\right) = \boxed{5.70\,\text{eV}}$$

(*c*) The energy due to repulsion of the ions at equilibrium separation is given by:

$$U_{\text{rep}} = E_{\text{d,calc}} - E_{\text{d,meas}}$$

Substitute numerical values and evaluate U_{rep}:

$$U_{\text{rep}} = 5.70\,\text{eV} - 5.07\,\text{eV} = \boxed{0.63\,\text{eV}}$$

Energy Levels of Spectra of Diatomic Molecules

22 • The characteristic rotational energy $E_{0\text{r}}$ for the rotation of a N_2 molecule is 2.48×10^{-4} eV. Using this value, find the separation distance of the 2 nitrogen atoms.

Picture the Problem We can relate the characteristic rotational energy $E_{0\text{r}}$ to the moment of inertia of the molecule and model the moment of inertia of the N_2 molecule as two point objects separated by a distance r.

The characteristic rotational energy of a molecule is given by:

$$E_{0r} = \frac{\hbar^2}{2I}$$

The moment of inertia of the molecule is given by:

$$I = 2M_{\text{N}}\left(\frac{r}{2}\right)^2 = \tfrac{1}{2}M_{\text{N}}r^2$$

Substitute for I to obtain:

$$E_{0r} = \frac{\hbar^2}{2\left(\frac{1}{2}M_{\text{N}}r^2\right)} = \frac{\hbar^2}{M_{\text{N}}r^2} = \frac{\hbar^2}{14m_{\text{p}}r^2}$$

Solving for r gives:

$$r = \hbar\sqrt{\frac{1}{14E_{0r}m_{\mathrm{p}}}}$$

Substitute numerical values and evaluate r:

$$r = \left(1.055\times10^{-34}\ \mathrm{J\cdot s}\right)\sqrt{\frac{1}{14\left(2.48\times10^{-4}\ \mathrm{eV}\right)\left(1.602\times10^{-19}\ \mathrm{J/eV}\right)\left(1.673\times10^{-27}\ \mathrm{kg}\right)}}$$
$$= \boxed{0.109\,\mathrm{nm}}$$

23 • [SSM] The separation of the two oxygen atoms in a molecule of O_2 is actually slightly greater than the 0.100 nm used in Example 37-3. Furthermore, the characteristic energy of rotation E_{0r} for O_2 is 1.78×10^{-4} eV rather than the result obtained in that example. Use this value to calculate the separation distance of the two oxygen atoms.

Picture the Problem We can relate the characteristic rotational energy E_{0r} to the moment of inertia of the molecule and model the moment of inertia of the O_2 molecule as two point objects separated by a distance r.

The characteristic rotational energy of a molecule is given by:

$$E_{0r} = \frac{\hbar^2}{2I}$$

The moment of inertia of the molecule is given by:

$$I = 2M_{\mathrm{O}}\left(\frac{r}{2}\right)^2 = \tfrac{1}{2}M_{\mathrm{O}}r^2$$

Substitute for I to obtain:

$$E_{0r} = \frac{\hbar^2}{2\left(\frac{1}{2}M_{\mathrm{O}}r^2\right)} = \frac{\hbar^2}{M_{\mathrm{O}}r^2} = \frac{\hbar^2}{16m_{\mathrm{p}}r^2}$$

Solving for r yields:

$$r = \frac{\hbar}{4}\sqrt{\frac{1}{E_{0r}m_{\mathrm{p}}}}$$

Substitute numerical values and evaluate r:

$$r = \left(\frac{1.055\times10^{-34}\ \mathrm{J\cdot s}}{4}\right)\sqrt{\frac{1}{\left(1.78\times10^{-4}\ \mathrm{eV}\right)\left(1.602\times10^{-19}\ \mathrm{J/eV}\right)\left(1.673\times10^{-27}\ \mathrm{kg}\right)}}$$
$$= \boxed{0.121\,\mathrm{nm}}$$

24 •• Show that the reduced mass of a diatomic molecule is always smaller than the mass of the molecule. Calculate the reduced mass for (*a*) H_2, (*b*) N_2, (*c*) CO, and (*d*) HCl. Express your answers in unified atomic mass units.

Picture the Problem We can use the definition of the reduced mass to show that the reduced mass is smaller than either mass in a diatomic molecule.

Express the reduced mass of a two-body system:

$$\mu = \frac{m_1 m_2}{m_1 + m_2}$$

Divide the numerator and denominator of this expression by m_2 to obtain:

$$\mu = \frac{m_1}{1 + \frac{m_1}{m_2}} \qquad (1)$$

Divide the numerator and denominator of this expression by m_1 to obtain:

$$\mu = \frac{m_2}{1 + \frac{m_2}{m_1}} \qquad (2)$$

Because the denominator is greater than 1 in equations (1) and (2):

$$\boxed{\mu < m_1} \text{ and } \boxed{\mu < m_2}$$

(*a*) For H_2, $m_1 = m_2 = 1$ u:

$$\mu_{H_2} = \frac{(1\,\text{u})(1\,\text{u})}{1\,\text{u} + 1\,\text{u}} = \boxed{0.500\,\text{u}}$$

(*b*) For N_2, $m_1 = m_2 = 14$ u:

$$\mu_{N_2} = \frac{(14\,\text{u})(14\,\text{u})}{14\,\text{u} + 14\,\text{u}} = \boxed{7.00\,\text{u}}$$

(*c*) For CO, $m_1 = 12$ u and $m_2 = 16$ u:

$$\mu_{CO} = \frac{(12\,\text{u})(16\,\text{u})}{12\,\text{u} + 16\,\text{u}} = \boxed{6.86\,\text{u}}$$

(*d*) For HCl, $m_1 = 1$ u and $m_2 = 35.5$ u:

$$\mu_{HCl} = \frac{(1\,\text{u})(35.5\,\text{u})}{1\,\text{u} + 35.5\,\text{u}} = \boxed{0.973\,\text{u}}$$

25 •• A CO molecule has a binding energy of approximately 11 eV. Find the vibrational quantum number ν that corresponds to 11 eV. (If a CO molecule actually had this much vibrational energy, it would ″shake″ apart.)

Picture the Problem We can solve Equation 37-18 for ν and substitute for the frequency of the CO molecule (see Example 37-4) and its binding energy to estimate the quantum number ν.

The vibrational energy levels are given by Equation 37-18:

$$E_\nu = \left(\nu + \tfrac{1}{2}\right)hf \Rightarrow \nu = \frac{E_\nu}{hf} - \frac{1}{2}$$

where $\nu = 0, 1, 2, \ldots, k$

Substitute numerical values and evaluate ν:

$$\nu = \frac{11\,\text{eV} \times \dfrac{1.602\times10^{-19}\ \text{J}}{\text{eV}}}{\left(6.626\times10^{-34}\ \text{J}\cdot\text{s}\right)\left(6.42\times10^{13}\ \text{Hz}\right)} - \frac{1}{2}$$

$$\approx \boxed{41}$$

26 •• Derive the equation $I = \mu r_0^2$ (Equation 37-14) for the moment of inertia in terms of the reduced mass of a diatomic molecule.

Picture the Problem Let the origin of coordinates be at the point mass m_1 and point mass m_2 be at a distance r_0 from the origin. We can express the moment of inertia of a diatomic molecule with respect to its center of mass using the definitions of the center of mass and the moment of inertia of point particles.

Express the moment of inertia of a diatomic molecule:

$$I = m_1 r_1^2 + m_2 r_2^2 \quad (1)$$

The r coordinate of the center of mass is:

$$r_{\text{CM}} = \frac{m_2}{m_1 + m_2} r_0$$

The distances of m_1 and m_2 from the center of mass are:

$$r_1 = r_{\text{CM}}$$

and

$$r_2 = r_0 - r_{\text{CM}} = r_0 - \frac{m_2}{m_1 + m_2} r_0$$

$$= \frac{m_1}{m_1 + m_2} r_0$$

Substitute for r_1 and r_2 in equation (1) to obtain:

$$I = m_1 \left(\frac{m_2}{m_1 + m_2} r_0\right)^2 + m_2 \left(\frac{m_1}{m_1 + m_2} r_0\right)^2$$

Simplifying this expression leads to:

$$I = \frac{m_1 m_2}{m_1 + m_2} r_0^2 \Rightarrow \boxed{I = \mu r_0^2} \quad \text{37-14}$$

where $\boxed{\mu = \dfrac{m_1 m_2}{m_1 + m_2}}$

27 •• [SSM] The equilibrium separation between the atoms of a LiH molecule is 0.16 nm. Determine the energy separation between the $\ell = 3$ and $\ell = 2$ rotational levels of this diatomic molecule.

Picture the Problem We can use the expression for the rotational energy levels of the diatomic molecule to express the energy separation ΔE between the $\ell = 3$ and $\ell = 2$ rotational levels and model the moment of inertia of the LiH molecule as two point objects separated by a distance r_0.

The energy separation between the $\ell = 3$ and $\ell = 2$ rotational levels of this diatomic molecule is given by:

$$\Delta E = E_{\ell=3} - E_{\ell=2}$$

Express the rotational energy levels $E_{\ell=3}$ and $E_{\ell=2}$ in terms of E_{0r}:

$$E_{\ell=3} = 3(3+1)E_{0r} = 12E_{0r}$$

and

$$E_{\ell=2} = 2(2+1)E_{0r} = 6E_{0r}$$

Substitute for $E_{\ell=3}$ and $E_{\ell=2}$ to obtain:

$$\Delta E = 12E_{0r} - 6E_{0r} = 6E_{0r}$$

The characteristic rotational energy of a molecule is given by $E_{0r} = \dfrac{\hbar^2}{2I}$. Hence:

$$\Delta E = 6\left(\frac{\hbar^2}{2I}\right) = \frac{3\hbar^2}{I}$$

The moment of inertia of the molecule is given by:

$$I = \mu r_0^2$$

where μ is the reduced mass of the molecule.

Substituting for I yields:

$$\Delta E = \frac{3\hbar^2}{\mu r_0^2} = \frac{3\hbar^2}{\dfrac{m_{\mathrm{Li}} m_{\mathrm{H}}}{m_{\mathrm{Li}} + m_{\mathrm{H}}} r_0^2} = \frac{3\hbar^2 (m_{\mathrm{Li}} + m_{\mathrm{H}})}{m_{\mathrm{Li}} m_{\mathrm{H}}\, r_0^2}$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = \frac{3(1.055\times10^{-34}\ \mathrm{J\cdot s})^2(6.94\,\mathrm{u} + 1\,\mathrm{u})}{(6.94\,\mathrm{u})(1\,\mathrm{u})(0.16\,\mathrm{nm})^2(1.602\times10^{-19}\ \mathrm{J/eV})(1.661\times10^{-27}\ \mathrm{kg/u})} = \boxed{5.6\,\mathrm{meV}}$$

28 •• The equilibrium separation of the K^+ and Cl^- ions in KCl is about 0.267 nm. Use this value together with the reduced mass of KCl to calculate the characteristic rotational energy E_{0r} (Equation 37-13) of KCl.

Picture the Problem We can relate the characteristic rotational energy E_{0r} to the moment of inertia of the molecule and model the moment of inertia of the KCl molecule as two point objects of reduced mass μ separated by a distance r.

The characteristic rotational energy of a molecule is given by:

$$E_{0r} = \frac{\hbar^2}{2I}$$

Express the moment of inertia of the molecule:

$$I = \mu r_0^2$$

where $\mu = \dfrac{m_K m_{Cl}}{m_K + m_{Cl}}$

Substituting for I and simplifying gives:

$$E_{0r} = \frac{\hbar^2}{2\mu r_0^2} = \frac{\hbar^2 (m_K + m_{Cl})}{2m_k m_{Cl} r_0^2}$$

Substitute numerical values and evaluate E_{0r}:

$$\begin{aligned} E_{0r} &= \frac{(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2 (39.1\,\text{u} + 35.5\,\text{u})}{2(39.1\text{u})(35.5\,\text{u})(0.267\,\text{nm})^2 (1.661\times10^{-27}\ \text{kg/u})} \\ &= 2.53\times10^{-24}\ \text{J}\times\frac{1}{1.602\times10^{-19}\ \text{J/eV}} = \boxed{0.0158\,\text{meV}} \end{aligned}$$

29 •• The central frequency for the absorption band of HCl shown in Figure 37-14 is at 8.66×10^{13} Hz, and the absorption peaks to either side of the central frequency are separated by about 6×10^{11} Hz. Use this information to find (*a*) the lowest (zero-point) vibrational energy for HCl, (*b*) the moment of inertia of HCl, and (*c*) the equilibrium separation of the two atoms.

Picture the Problem We can use the expression for the vibrational energies of a molecule to find the lowest vibrational energy. Because the difference in the vibrational energy levels depends on both Δf and the moment of inertia I of the molecule, we can relate these quantities and solve for I. Finally, we can use $I = \mu r^2$, with μ representing the reduced mass of the molecule, to find the equilibrium separation of the atoms.

(*a*) The vibrational energy levels are given by:

$$E_\nu = \left(\nu + \tfrac{1}{2}\right)hf, \quad \nu = 0,1,2,\ldots$$

The lowest vibrational energy corresponds to $\nu = 0$:

$$E_0 = \tfrac{1}{2}hf$$

Substitute numerical values and evaluate E_0:

$$E_0 = \tfrac{1}{2}\left(6.626\times10^{-34}\ \text{J}\cdot\text{s}\right)\left(8.66\times10^{13}\ \text{Hz}\right) = 2.87\times10^{-20}\ \text{J}\times\frac{1}{1.602\times10^{-19}\ \text{J/eV}}$$

$$= \boxed{0.179\,\text{eV}}$$

(*b*) For $\Delta\ell = \pm1$:

$$\Delta E_\ell = \frac{\ell\hbar^2}{I} = \ell h\Delta f$$

Solving for I and simplifying gives:

$$I = \frac{\hbar^2}{h\Delta f} = \frac{h^2}{4\pi^2 h\Delta f} = \frac{h}{4\pi^2\Delta f}$$

Substitute numerical values and evaluate I:

$$I = \frac{6.626\times10^{-34}\ \text{J}\cdot\text{s}}{4\pi^2\left(6\times10^{11}\ \text{Hz}\right)}$$

$$= 2.80\times10^{-47}\ \text{kg}\cdot\text{m}^2$$

$$\approx \boxed{3\times10^{-47}\ \text{kg}\cdot\text{m}^2}$$

(*c*) The moment of inertia of a HCL molecule is given by:

$$I = \mu r^2$$

Replace μ by the reduced mass of a HCl molecule and r by r_0 to obtain:

$$I = \frac{m_\text{H}m_\text{Cl}}{m_\text{H}+m_\text{Cl}}r_0^2 \Rightarrow r_0 = \sqrt{\frac{m_\text{H}+m_\text{Cl}}{m_\text{H}m_\text{Cl}}I}$$

Substitute numerical values and evaluate r_0:

$$r_0 = \sqrt{\left[\frac{1\text{u}+34.453\text{u}}{(1\text{u})(34.453\text{u})}\right]\frac{\left(2.80\times10^{-47}\ \text{kg}\cdot\text{m}^2\right)}{1.661\times10^{-27}\ \text{kg/u}}} = \boxed{0.1\text{nm}}$$

30 •• Calculate the effective force constant for HCl from its reduced mass and from the fundamental vibrational frequency obtained from Figure 37-14.

Picture the Problem Let the numeral 1 refer to the H^+ and the numeral 2 to the Cl^- ion. For a two-mass and spring system on which no external forces are acting, the center of mass must remain fixed. We can use this condition to express the net force acting on either the H^+ or Cl^- ion. Because this force is a linear restoring

force, we can conclude that the motion of the object whose mass is m_1 will be simple harmonic with an angular frequency given by $\omega = \sqrt{k_{\text{eff}}/m_1}$.

If the particle whose mass is m_1 moves a distance r_1 from (or toward) the center of mass, then the particle whose mass is m_2 must move a distance:

$\Delta r_2 = \frac{m_1}{m_2}\Delta r_1$ from (or toward) the center of mass.

Express the force exerted by the spring:

$$F = -k\Delta r = -k(\Delta r_1 + \Delta r_2)$$

Substitute for Δr_2 to obtain:

$$F = -k\left(\Delta r_1 + \frac{m_1}{m_2}\Delta r_1\right) = -k\left(\frac{m_1 + m_2}{m_2}\right)\Delta r_1$$

A displacement Δr_1 of m_1 results in a restoring force:

$$F = -k\left(\frac{m_1 + m_2}{m_2}\right)\Delta r_1 = -k_{\text{eff}}\Delta r_1$$

where $k_{\text{eff}} = k\left(\frac{m_1 + m_2}{m_2}\right)$

Because this is a linear restoring force, we know that the motion will be simple harmonic with the angular frequency given by:

$$\omega = \sqrt{\frac{k_{\text{eff}}}{m_1}} \Rightarrow 2\pi f = \sqrt{\frac{k_{\text{eff}}}{m_1}}$$

Substitute for k_{eff} and simplify to obtain:

$$2\pi f = \sqrt{k\left(\frac{m_1 + m_2}{m_1 m_2}\right)}$$

or, because $\mu = \frac{m_1 m_2}{m_1 + m_2} = \frac{m_{\text{H}} m_{\text{Cl}}}{m_{\text{H}} + m_{\text{Cl}}}$ is the reduced mass of the two-particle system, $2\pi f = \sqrt{\frac{k}{\mu}}$

Solving for k yields:

$$k = 4\pi^2 f^2 \mu = 4\pi^2 f^2 \frac{m_{\text{H}} m_{\text{Cl}}}{m_{\text{H}} + m_{\text{Cl}}}$$

Substitute numerical values and evaluate k:

$$k = \frac{4\pi^2\left(8.66\times10^{13}\text{ Hz}\right)^2(1\text{u})(35.453\text{u})\left(1.661\times10^{-27}\text{ kg/u}\right)}{(1\text{u}+35.453\text{u})} = \boxed{478\,\text{N/m}}$$

31 •• [SSM] The equilibrium separation between the atoms of a CO molecule is 0.113 nm. For a molecule, such as CO, that has a permanent electric dipole moment, radiative transitions obeying the selection rule $\Delta\ell = \pm1$ between two rotational energy levels of the same vibrational level are allowed. (That is, the selection rule $\Delta\nu = \pm1$ does not hold.) (*a*) Find the moment of inertia of CO and calculate the characteristic rotational energy E_{0r} (in eV). (*b*) Make an energy-level diagram for the rotational levels from $\ell = 0$ to $\ell = 5$ for some vibrational level. Label the energies in electron volts, starting with $E = 0$ for $\ell = 0$. Indicate on your diagram the transitions that obey $\Delta\ell = -1$, and calculate the energies of the photons emitted. (*c*) Find the wavelength of the photons emitted during each transition in (*b*). In what region of the electromagnetic spectrum are these photons?

Picture the Problem We can find the reduced mass of CO and the moment of inertia of a CO molecule from their definitions. The energy level diagram for the rotational levels from $\ell = 0$ to $\ell = 5$ can be found using $\Delta E_{\ell,\ell-1} = 2\ell E_{0r}$. Finally, we can find the wavelength of the photons emitted for each transition using $\lambda_{\ell,\ell-1} = \dfrac{hc}{\Delta E_{\ell,\ell-1}} = \dfrac{hc}{2\ell\Delta E_{0r}}$.

(*a*) Express the moment of inertia of CO:

$$I = \mu r_0^2$$

where μ is the reduced mass of the CO molecule.

The reduced mass of the CO molecule is given by:

$$\mu = \frac{m_C m_O}{m_C + m_O}$$

Substituting for μ gives:

$$I = \frac{m_C m_O r_0^2}{m_C + m_O}$$

Substitute numerical values (r_0 = 0.113 nm) and evaluate I:

$$I = \left(\frac{(12\,\text{u})(16\,\text{u})}{12\,\text{u}+16\,\text{u}}\right)(1.661\times10^{-27}\ \text{kg/u})(0.113\,\text{nm})^2 = 1.454\times10^{-46}\ \text{kg}\cdot\text{m}^2$$
$$= \boxed{1.45\times10^{-46}\ \text{kg}\cdot\text{m}^2}$$

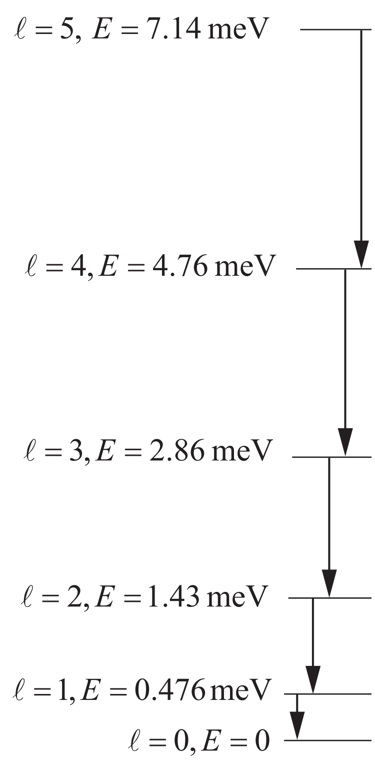
The characteristic rotational energy E_{0r} is given by:

$$E_{0r} = \frac{\hbar^2}{2I}$$

Substitute numerical values and evaluate E_{0r}:

$$E_{0r} = \frac{(6.58\times10^{-16}\ \text{eV}\cdot\text{s})^2(1.602\times10^{-19}\ \text{J/eV})}{2(1.454\times10^{-46}\ \text{kg}\cdot\text{m}^2)} = 0.2385\,\text{meV} = \boxed{0.239\,\text{meV}}$$

(*b*) The energy level diagram is shown to the right. Note that $\Delta E_{\ell,\ell-1}$, the energy difference between adjacent levels for $\Delta\ell = -1$, is $\Delta E_{\ell,\ell-1} = 2\ell E_{0r}$.



The energies of the photons emitted in each transition are given by $\Delta E_{\ell,\ell-1}$. Hence:

$$\Delta E_{5,4} = 7.14\,\text{meV} - 4.76\,\text{meV} = \boxed{2.38\,\text{meV}}$$

$$\Delta E_{4,3} = 4.76\,\text{meV} - 2.86\,\text{meV} = \boxed{1.90\,\text{meV}}$$

$$\Delta E_{3,2} = 2.86\,\text{meV} - 1.43\,\text{meV} = \boxed{1.43\,\text{meV}}$$

$$\Delta E_{2,1} = 1.43\,\text{meV} - 0.476\,\text{meV} = \boxed{1.25\,\text{meV}}$$

$$\Delta E_{1,0} = 0.476\,\text{meV} - 0 = \boxed{0.476\,\text{meV}}$$

(*c*) Express the energy difference $\Delta E_{\ell.\ell-1}$ between energy levels in terms of the frequency of the emitted radiation:

$$\Delta E_{\ell,\ell-1} = hf_{\ell,\ell-1}$$

Because $c = f_{\ell,\ell-1}\lambda_{\ell,\ell-1}$:

$$\lambda_{\ell,\ell-1} = \frac{hc}{\Delta E_{\ell,\ell-1}} = \frac{hc}{2\ell\Delta E_{0r}}$$

Substitute numerical values to obtain:

$$\lambda_{\ell,\ell-1} = \frac{(4.136\times10^{-15}\ \text{eV}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{2\ell(0.2385\,\text{meV})} = \frac{2600\,\mu\text{m}}{\ell}$$

For ℓ = 1:

$$\lambda_{1,0} = \frac{2600\,\mu\text{m}}{1} = \boxed{2600\,\mu\text{m}}$$

For ℓ = 2:

$$\lambda_{2,1} = \frac{2600\,\mu\text{m}}{2} = \boxed{1300\,\mu\text{m}}$$

For ℓ = 3:

$$\lambda_{3,2} = \frac{2600\,\mu\text{m}}{3} = \boxed{867\,\mu\text{m}}$$

For ℓ = 4:

$$\lambda_{4,3} = \frac{2600\,\mu\text{m}}{4} = \boxed{650\,\mu\text{m}}$$

For $\ell = 5$:

$$\lambda_{5,4} = \frac{2600\,\mu\text{m}}{5} = \boxed{520\,\mu\text{m}}$$

These wavelengths fall in the microwave region of the electromagnetic spectrum.

32 •• Two objects, one of mass m_1 and the other of mass m_2, are connected to opposite ends of a spring of force constant k_F. The objects are released from rest with the spring compressed. (*a*) Show that when the spring is extended and the object of mass m_1 is a distance Δr_1 from its equilibrium position in the center-of-mass reference frame, the force exerted by the spring is given by $F = -k_F(m_1/\mu)\Delta r_1$, where μ is the reduced mass. (*b*) Show that the frequency of oscillation f is related to k and μ by $2\pi f = \sqrt{k_F/\mu}$.

Picture the Problem For a two-mass and spring system on which no external forces are acting, the center of mass must remain fixed. We can use this condition to express the net force acting on either object. Because this force is a linear restoring force, we can conclude that the motion of the object whose mass is m_1 will be simple harmonic with an angular frequency given by $\omega = \sqrt{k_{\text{eff}}/m_1}$. Substitution for k_{eff} will lead us to the result given in (*b*).

(*a*) If the particle whose mass is m_1 moves a distance Δr_1 from (or toward) the center of mass, then the particle whose mass is m_2 must move a distance:

$\Delta r_2 = \dfrac{m_1}{m_2}\Delta r_1$ from (or toward) the center of mass.

Express the force exerted by the spring:

$$F = -k_F \Delta r = -k_F(\Delta r_1 + \Delta r_2)$$

Substitute for Δr_2 and simplify to obtain:

$$F = -k_F\left(\Delta r_1 + \frac{m_1}{m_2}\Delta r_1\right)$$

$$= -k_F\left(\frac{m_1 + m_2}{m_2}\right)\Delta r_1$$

$$= -k_F\left(\frac{m_1}{\dfrac{m_1 m_2}{m_1 + m_2}}\right)\Delta r_1 = \boxed{-k_F\left(\frac{m_1}{\mu}\right)\Delta r_1}$$

where $\mu = \dfrac{m_1 m_2}{m_1 + m_2}$ is the reduced mass of the spring and mass oscillator.

(*b*) A displacement Δr_1 of m_1 results in a restoring force given by:

$$F = -k_F\left(\frac{m_1 + m_2}{m_2}\right)\Delta r_1 = -k_{eff}\,\Delta r_1$$

where $k_{eff} = k_F\left(\frac{m_1 + m_2}{m_2}\right)$

Because this is a linear restoring force, we know that the motion will be simple harmonic with an angular frequency given by:

$$\omega = \sqrt{\frac{k_{eff}}{m_1}} \Rightarrow f = \frac{\omega}{2\pi} = \frac{1}{2\pi}\sqrt{\frac{k_{eff}}{m_1}}$$

Substitute for k_{eff} and simplify to obtain:

$$f = \frac{\omega}{2\pi} = \frac{1}{2\pi}\sqrt{k_F\left(\frac{m_1 + m_2}{m_1 m_2}\right)}$$

or, because $\mu = \frac{m_1 m_2}{m_1 + m_2}$ is the reduced mass of the two-particle system,

$$2\pi f = \boxed{\sqrt{\frac{k_F}{\mu}}}\,.$$

33 ••• Calculate the reduced masses for $H^{35}Cl$ and $H^{37}Cl$ molecules and the fractional difference $\Delta\mu/\mu$. Show that the mixture of isotopes in HCl leads to a fractional difference in the frequency of a transition from one rotational state to another given by $\Delta f/f = -\Delta\mu/\mu$. Compute $\Delta f/f$ and compare your result with Figure 37-17.

Picture the Problem We can use the definition of the reduced mass to find the reduced mass for the $H^{35}Cl$ and $H^{37}Cl$ molecules and the fractional difference $\Delta\mu/\mu$. Because the rotational frequency is proportional to $1/I$, where I is the moment of inertia of the system, and I is proportional to μ, we can obtain an expression for f as a function of μ that we differentiate implicitly to show that $\Delta f/f = -\Delta\mu/\mu$.

For $H^{35}Cl$:

$$\mu_{H^{35}Cl} = \frac{(35\,u)(1\,u)}{35\,u + 1\,u} = \frac{35}{36}\,u = \boxed{0.972\,u}$$

For $H^{37}Cl$:

$$\mu_{H^{37}Cl} = \frac{(37\,u)(1\,u)}{37\,u + 1\,u} = \frac{37}{38}\,u = \boxed{0.974\,u}$$

The fractional difference is:

$$\frac{\Delta\mu}{\mu}=\frac{\frac{37}{38}\text{u}-\frac{35}{36}\text{u}}{\frac{1}{2}\left(\frac{35}{36}\text{u}+\frac{37}{38}\text{u}\right)}=\frac{\frac{36\times37-35\times38}{36\times38}\text{u}}{\frac{35\times38+36\times37}{2(36)(38)}\text{u}}=\boxed{0.00150}$$

The rotational frequency is proportional to I^{-1}, where I is the moment of inertia of the system. Because I is proportional to μ:

$$f=\frac{C}{\mu}$$

and

$$df=-C\mu^{-2}d\mu$$

Divide df by f to obtain:

$$\frac{df}{f}=-\frac{d\mu}{\mu}\text{ and }\frac{\Delta f}{f}\approx-\frac{\Delta\mu}{\mu}$$

From Figure 37-17:

$$\Delta f\approx0.01\times10^{13}\text{ Hz}=1\times10^{11}\text{ Hz}$$

For $f = 8.40\times10^{13}$ Hz:

$$\frac{\Delta f}{f}\approx\frac{1\times10^{11}\text{ Hz}}{8.40\times10^{13}\text{ Hz}}=\boxed{0.001}$$

This result is in fair agreement (about 20% difference) with the calculated result. Note that Δf is difficult to determine precisely from Figure 37-17.

General Problems

34 • Show that when one atom of a diatomic molecule is much more massive than the other the reduced mass is approximately equal to the mass of the lighter atom.

Picture the Problem We can use the definition of the reduced mass to show that when one atom in a diatomic molecule is much more massive than the other the reduced mass is approximately equal to the mass of the lighter atom.

Express the reduced mass of a two-body system:

$$\mu=\frac{m_1m_2}{m_1+m_2}$$

Divide the numerator and denominator of this expression by m_2 to obtain:

$$\mu=\frac{m_1}{1+\frac{m_1}{m_2}}$$

If $m_2 >> m_1$, then: $\frac{m_1}{m_2} << 1$ and $\boxed{\mu \approx m_1}$

35 •• The equilibrium separation between the nuclei of a CO molecule is 0.113 nm. Determine the energy difference between the $\ell = 2$ and $\ell = 1$ rotational energy levels of this molecule.

Picture the Problem The rotational energy levels are given by $E = \frac{\ell(\ell+1)\hbar^2}{2I}, \ell = 0, 1, 2, ...$

Express the energy difference between these rotational energy levels:

$$\Delta E_{1,2} = E_2 - E_1$$

Express E_2 and E_1:

$$E_2 = \frac{2(2+1)\hbar^2}{2I} = \frac{3\hbar^2}{I}$$

and

$$E_1 = \frac{1(1+1)\hbar^2}{2I} = \frac{\hbar^2}{I}$$

Substitute to obtain:

$$\Delta E_{1,2} = \frac{3\hbar^2}{I} - \frac{\hbar^2}{I} = \frac{2\hbar^2}{I}$$

The moment of inertia of the molecule is given by:

$$I = \mu r_0^2$$

where μ is the reduced mass of the molecule.

Substituting for I yields:

$$\Delta E_{1,2} = \frac{2\hbar^2}{\mu r_0^2} = \frac{2\hbar^2}{\frac{m_C m_O}{m_C + m_O} r_0^2} = \frac{2\hbar^2 (m_C + m_O)}{m_C m_O r_0^2}$$

Substitute numerical values and evaluate $\Delta E_{1,2}$:

$$\Delta E_{1,2} = \frac{2(1.055\times10^{-34}\ \text{J}\cdot\text{s})^2 (12\,\text{u} + 16\,\text{u})}{(16\,\text{u})(12\,\text{u})(0.113\,\text{nm})^2 (1.661\times10^{-27}\ \text{kg/u})(1.602\times10^{-19}\ \text{J/eV})} = \boxed{0.955\ \text{meV}}$$

36 •• The effective force constant for a HF molecule is 970 N/m. Find the frequency of vibration for this molecule.

Picture the Problem We can use the result of Problem 32 to find the frequency of vibration of the HF molecule.

In Problem 32 it was established that:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{\mu}}$$ where μ is the reduced mass of the HF molecule.

The reduced mass of the HF molecule is given by:

$$\mu = \frac{m_H m_F}{m_H + m_F}$$

Substitute for μ and simplify to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{\frac{m_H m_F}{m_H + m_F}}} = \frac{1}{2\pi}\sqrt{\frac{k(m_H + m_F)}{m_H m_F}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{(970\,\text{N/m})(1\,\text{u} + 19\,\text{u})}{(1\,\text{u})(19\,\text{u})(1.661\times10^{-27}\,\text{kg/u})}} = \boxed{1.25\times10^{14}\,\text{Hz}}$$

37 •• The frequency of vibration of a NO molecule is 5.63×10^{13} Hz. Find the effective force constant for NO.

Picture the Problem We can use the result of Problem 32 to find the effective force constant for NO.

In Problem 32 it was established that:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{\mu}} \Rightarrow k = 4\pi^2 f^2 \mu$$ where μ is the reduced mass of a NO molecule.

The reduced mass of the NO molecule is given by:

$$\mu = \frac{m_N m_O}{m_N + m_O}$$

Substituting for μ gives:

$$k = \frac{4\pi^2 f^2 m_N m_O}{m_N + m_O}$$

Substitute numerical values and evaluate k:

$$k=\frac{4\pi^2\left(5.63\times10^{13}\ \mathrm{s}^{-1}\right)^2(14\,\mathrm{u})(16\,\mathrm{u})\left(1.661\times10^{-27}\ \mathrm{kg/u}\right)}{14\,\mathrm{u}+16\,\mathrm{u}}=\boxed{1.55\,\mathrm{kN/m}}$$

38 •• The effective force constant of the hydrogen bond in a H_2 molecule is 580 N/m. Obtain the energies of the four lowest vibrational levels of the H_2, HD, and D_2 molecules, where H is protium and D is deuterium, and find the wavelengths of photons resulting from transitions between adjacent vibrational levels for each of these molecules.

Picture the Problem We can use the expression for the vibrational energy levels of a molecule and the expression for the frequency of oscillation from Problem 32 to find the four lowest vibrational levels of the given molecules.

The vibrational energy levels are given by:

$$E_\nu=\left(\nu+\tfrac{1}{2}\right)hf,\ \text{where}\ \nu=0,1,2,\ldots$$

In Problem 32 we showed that the frequency of oscillation is:

$$f=\frac{1}{2\pi}\sqrt{\frac{k}{\mu}}\ \text{ where }\ \mu=\frac{m_1m_2}{m_1+m_2}$$

Substitute for f and μ to obtain:

$$E_\nu=\frac{\left(\nu+\frac{1}{2}\right)h}{2\pi}\sqrt{\frac{(m_1+m_2)k}{m_1m_2}}=\frac{\left(\nu+\frac{1}{2}\right)h}{2\pi}\sqrt{k}\sqrt{\frac{(m_1+m_2)}{m_1m_2}}$$

Substitute numerical values to obtain:

$$E_\nu=\frac{\left(\nu+\frac{1}{2}\right)\left(4.136\times10^{-15}\ \mathrm{eV\cdot s}\right)}{2\pi}\sqrt{\frac{580\,\mathrm{N/m}}{1.661\times10^{-27}\ \mathrm{kg/u}}}\sqrt{\frac{(m_1+m_2)}{m_1m_2}}=\left(\nu+\tfrac{1}{2}\right)(0.389\,\mathrm{eV\cdot u})\sqrt{\frac{(m_1+m_2)}{m_1m_2}}$$

Substitute for m_1 and m_2 and evaluate E_0 for H_2:

$$E_0=\tfrac{1}{2}(0.389\,\mathrm{eV\cdot u})\sqrt{\frac{(1\,\mathrm{u}+1\,\mathrm{u})}{(1\,\mathrm{u})(1\,\mathrm{u})}}=0.275\,\mathrm{eV}$$

Proceed similarly to complete the table to the right:

	H_2	HD	D_2
	(eV)	(eV)	(eV)
0	$\boxed{0.275}$	$\boxed{0.238}$	$\boxed{0.195}$
1	$\boxed{0.825}$	$\boxed{0.715}$	$\boxed{0.584}$
2	$\boxed{1.375}$	$\boxed{1.191}$	$\boxed{0.973}$
3	$\boxed{1.925}$	$\boxed{1.667}$	$\boxed{1.362}$

The energies of the photons resulting from transitions between adjacent vibrational levels of these molecules are given by:

$$\Delta E = hf = \frac{hc}{\lambda} \Rightarrow \lambda = \frac{hc}{\Delta E}$$

Evaluate $\lambda(H_2)$:

$$\lambda(\mathrm{H}_2) = \frac{1240\,\mathrm{eV\cdot nm}}{0.550\,\mathrm{eV}} = \boxed{2.25\,\mu\mathrm{m}}$$

Evaluate $\lambda(\mathrm{HD})$:

$$\lambda(\mathrm{HD}) = \frac{1240\,\mathrm{eV\cdot nm}}{0.477\,\mathrm{eV}} = \boxed{2.60\,\mu\mathrm{m}}$$

Evaluate $\lambda(D_2)$:

$$\lambda(\mathrm{D}_2) = \frac{1240\,\mathrm{eV\cdot nm}}{0.389\,\mathrm{eV}} = \boxed{3.19\,\mu\mathrm{m}}$$

39 •• The potential energy between two atoms in a molecule separated by a distance r can often be described rather well by the Lenard–Jones (or 6-12) potential function, which can be written as

$$U = U_0\left[\left(\frac{a}{r}\right)^{12} - 2\left(\frac{a}{r}\right)^{6}\right]$$

where U_0 and a are constants. Find the equilibrium separation r_0 in terms of a. *Hint: At the equilibrium separation the potential energy is a minimum.* Find U_{min}, the value of U when $r = r_0$. Use Figure 37-4 to obtain numerical values of r_0 and U_0 for a H_2 molecule, and express your answers in nanometers and electron volts.

Picture the Problem We can set the derivative of the potential energy function equal to zero to find the value of r for which it is either a maximum or a minimum. Examination of the second derivative of this function at the value for r obtained from setting the first derivative equal to zero will establish whether the function is a relative maximum or relative minimum at this point.

Differentiate the potential energy function with respect to r:

$$\frac{dU}{dr}=\frac{d}{dr}\left\{U_0\left[\left(\frac{a}{r}\right)^{12}-2\left(\frac{a}{r}\right)^{6}\right]\right\}$$
$$=-\frac{U_0}{r}\left[12\left(\frac{a}{r}\right)^{11}-12\left(\frac{a}{r}\right)^{5}\right]$$

Set the derivative equal to zero for extrema:

$$\frac{dU}{dr}=-\frac{U_0}{r_0}\left[12\left(\frac{a}{r_0}\right)^{11}-12\left(\frac{a}{r_0}\right)^{5}\right]=0$$

Solve for r_0 to obtain a candidate for r that minimizes the Lenard-Jones potential:

$$r_0=\boxed{a}$$

To show that $r_0 = a$ corresponds to a minimum, differentiate U a second time to obtain:

$$\frac{d^2U}{dr^2}=\frac{d}{dr}\left\{-\frac{U_0}{r}\left[12\left(\frac{a}{r}\right)^{11}-12\left(\frac{a}{r}\right)^{5}\right]\right\}$$
$$=\frac{U_0}{r^2}\left[132\left(\frac{a}{r}\right)^{10}-60\left(\frac{a}{r}\right)^{4}\right]$$

Evaluate this second derivative of the potential at $r_0 = a$:

$$\left.\frac{d^2U}{dr^2}\right|_{r=a}=\frac{U_0}{a^2}[132-60]=\frac{72U_0}{a^2}>0$$

Therefore, we can conclude that $r_0 = a$ minimizes the potential function.

Evaluate $U_{\min}$:

$$U_{\min}=U(a)=U_0\left[\left(\frac{a}{a}\right)^{12}-2\left(\frac{a}{a}\right)^{6}\right]$$
$$=\boxed{-U_0}$$

From Figure 37-4:

$$r_0=\boxed{0.074\,\text{nm}}$$

and

$$U_0=\boxed{4.52\,\text{eV}}$$

40 •• In this problem, you are to determine how the van der Waals force between a polar molecule and a nonpolar molecule depends on the distance between the molecules. Let the polar molecule be at the origin and let its dipole moment be in the +x direction. In addition, let the nonpolar molecule be on the x axis a distance x away. (a) How does the electric field strength due to an electric

dipole vary with the distance from the dipole in a given direction? (*b*) Use (1) that the potential energy *U* of an electric dipole of dipole moment $\vec{\boldsymbol{p}}$ in an electric field $\vec{\boldsymbol{E}}$ can be expressed as $U = -\vec{\boldsymbol{p}} \cdot \vec{\boldsymbol{E}}$, and (2) that the induced dipole moment $\vec{\boldsymbol{p}}'$ of the nonpolar molecule is in the direction of $\vec{\boldsymbol{E}}$, and that p' is proportional to *E*, to determine how the potential energy of interaction of the two molecules depends on the separation distance *x*. (*c*) Using $F_x = -dU/dx$, determine how the force between the two molecules depends on distance.

Picture the Problem We can use Equation 21-10 to establish the dependence of *E* on *x* and the dependence of an induced dipole on the field that induces it to establish the dependence of *p* and *U* on *x*.

(*a*) In terms of the dipole moment, the electric field on the axis of the dipole at a point a great distance $|x|$ away has the magnitude (see Equation 21-10):

$$E = \frac{2kp}{|x|^3} \Rightarrow E \propto \boxed{\frac{1}{|x|^3}}$$

(*b*) Because the induced dipole moment is proportional to the field that induces it:

$$p \propto \boxed{\frac{1}{x^3}} \text{ and } U = -\vec{\boldsymbol{p}} \cdot \vec{\boldsymbol{E}} \propto \boxed{\frac{1}{x^6}}$$

(*c*) Differentiate *U* with respect to *x* to obtain:

$$F_x = -\frac{dU}{dx} \propto \boxed{\frac{1}{x^7}}$$

41 •• Find the dependence of the force on the separation distance between the two polar molecules described in Problem 40.

Picture the Problem For the case of two polar molecules, *p* does not depend on the field *E*. The dependence of *F* on the separation distance *x* can be found from *dU*/*dx*.

Because *p* does not depend on the electric field in which the polar molecules find themselves:

$$U \propto \frac{1}{x^3}$$

Differentiate *U* with respect to *x* to obtain:

$$F_x = -\frac{dU}{dx} \propto \boxed{\frac{1}{x^4}}$$

42 •• Use the infrared absorption spectrum of HCl in Figure 37-17 to obtain (*a*) the characteristic rotational energy E_{0r} (in eV) and (*b*) find vibrational frequency f and the vibrational energy hf (in eV).

Picture the Problem (*a*) Except for a gap of $4E_{0r}/h$ at the vibrational frequency f, the absorption spectrum contains frequencies equally spaced at $2E_{0r}/h$. We can measure this spacing of the absorption peaks to obtain E_{0r}. (*b*) We can use the expression for the vibrational and rotational energies of a molecule, in conjunction with Figure 37-17 to find f and hf.

(*a*) Letting Δf represent the frequency gap, we have:

$$\Delta f = \frac{2E_{0r}}{h} \Rightarrow E_{0r} = \tfrac{1}{2}h\Delta f$$

Estimating from Figure 37-17, the frequency gap is approximately:

$$\Delta f = 7.0\times10^{11}\text{ Hz}$$

where the peaks at 8.40×10^{13} Hz and 8.61×10^{13} Hz were used.

Substitute numerical values and evaluate E_{0r}:

$$E_{0r} = \tfrac{1}{2}\left(4.136\times10^{-15}\text{ eV}\cdot\text{s}\right)\left(7.0\times10^{11}\text{ Hz}\right) = \boxed{1.4\text{ meV}}$$

(*b*) The vibrational energy levels are given by:

$$E_\nu = \left(\nu+\tfrac{1}{2}\right)hf,\quad \nu = 0,1,2,\ldots$$

The lowest vibrational energy corresponds to $\nu = 0$:

$$E_0 = \tfrac{1}{2}hf \Rightarrow hf = 2E_0 \qquad (1)$$

Determine f from Figure 37-17:

$$f = \boxed{8.66\times10^{13}\text{ Hz}}$$

Substitute for f and h and evaluate E_0:

$$E_0 = \tfrac{1}{2}\left(4.136\times10^{-15}\text{ eV}\cdot\text{s}\right)\left(8.66\times10^{13}\text{ Hz}\right) = 0.179\text{ eV}$$

Substitute in equation (1) and evaluate hf:

$$hf = 2\left(0.179\,\text{eV}\right) = \boxed{0.358\,\text{eV}}$$

43 • The dissociation energy is sometimes expressed in kilocalories per mole (kcal/mol). (*a*) Find the relation between the units eV/molecule and kcal/mol. (*b*) Find the dissociation energy of NaCl in kcal/mol.

Picture the Problem We can use conversion factors to convert eV/molecule into kcal/mol.

(*a*)

$$1\frac{\text{eV}}{\text{molecule}}=1\frac{\text{eV}}{\text{molecule}}\times\frac{1\,\text{kcal}}{4184\,\text{J}}\times\frac{6.022\times10^{23}\text{ molecules}}{\text{mole}}\times\frac{1.602\times10^{-19}\text{ J}}{\text{eV}}$$
$$=\boxed{23.0\,\text{kcal/mol}}$$

(*b*) The dissociation energy of NaCl, in eV/molecule, is 4.27 eV/molecule. Using the conversion factor in (*a*), express this energy in kcal/mol:

$$\frac{4.27\,\text{eV}}{\text{molecule}}\times\frac{23.0\,\text{kcal}}{\text{mol}}=\boxed{98.2\,\text{kcal/mol}}$$

Chapter 38
Solids

Conceptual Problems

1 • In the classical model of conduction, the electron loses energy on average during a collision because it loses the drift velocity it had acquired since the last collision. Where does this energy appear?

Determine the Concept The energy lost by the electrons in collision with the ions of the crystal lattice appears as Joule heat (I^2R).

2 • A metal is a good conductor because the valence energy band for electrons is (*a*) empty, (*b*) partly filled, (*c*) filled, but there is only a small gap to a higher empty band, (*d*) completely filled, (*e*) None of the above.

Determine the Concept If the valence band is only partially full, there are many available empty energy states in the band, and the electrons in the band can easily be raised to a higher energy state by an electric field. $\boxed{(b)}$ is correct.

3 • Thomas refuses to believe that a potential difference can be created simply by bringing two different metals into contact with each other. John talks him into making a small wager and is about to win the bet. (*a*) Which two metals from Table 38-2 would demonstrate his point most effectively? (*b*) What is the value of that contact potential?

Picture the Problem The contact potential is given by $V_{\text{contact}} = \dfrac{\phi_1 - \phi_2}{e}$, where ϕ_1 and ϕ_2 are the work functions of the two different metals in contact with each other.

(*a*) Express the contact potential in terms of the work functions of the metals:

$$V_{\text{contact}} = \frac{\phi_1 - \phi_2}{e}$$

Examining Table 38-2, we see that the greatest difference between the work functions will occur when potassium and nickel are joined.

(*b*) Substitute numerical values and evaluate V_{contact}:

$$V_{\text{contact}} = \frac{5.2\,\text{eV} - 2.1\,\text{eV}}{e} = \boxed{3.1\,\text{V}}$$

4 • (*a*) In Problem 3, which choices of different metals would make the least impressive demonstration? (*b*) What is the value of that contact potential?

Picture the Problem The contact potential is given by $V_{\text{contact}} = \frac{\phi_1 - \phi_2}{e}$, where ϕ_1 and ϕ_2 are the work functions of the two different metals in contact with each other.

(*a*) Express the contact potential in terms of the work functions of the metals:

$$V_{\text{contact}} = \frac{\phi_1 - \phi_2}{e}$$

Examining Table 38-2, we see that the least difference between the work functions will occur when silver and gold are joined.

(*b*) Substitute numerical values and evaluate V_{contact}:

$$V_{\text{contact}} = \frac{4.8\,\text{eV} - 4.7\,\text{eV}}{e} = \boxed{0.1\,\text{V}}$$

5 • [SSM] When a sample of pure copper is cooled from 300 K to 4 K, its resistivity decreases more than the resistivity of a sample of brass when it is cooled through the same temperature difference. Why?

Determine the Concept The resistivity of brass at 4 K is almost entirely due to the ″residual resistance,″ the resistance due to impurities and other imperfections of the crystal lattice. In brass, the zinc ions act as impurities in copper. In pure copper, the resistivity at 4 K is due to its residual resistance, which is very low if the copper is very pure.

6 • Insulators are poor conductors of electricity because (*a*) there is a small energy gap between the filled valence band and the next higher band where electrons can exist, (*b*) there is a large energy gap between the completely filled valence band and the next higher band where electrons can exist, (*c*) the valence band has a few vacancies for electrons, (*d*) the valence band is only partly filled, (*e*) None of the above.

Determine the Concept Insulators are poor conductors of electricity because there is a large energy gap between the filled valence band and the next higher band where electrons can exist. $\boxed{(b)}$ is correct.

7 • [SSM] How does the sign of the change in the resistivity of a sample of copper compare with the sign of the change of the resistivity of a sample of silicon when the temperatures of both samples increase?

Determine the Concept The resistivity of copper increases with increasing temperature; the resistivity of (pure) silicon decreases with increasing temperature because the number of charge carriers increases.

8 • True or false:

(*a*) Solids that are good electrical conductors are usually good heat conductors.
(*b*) At $T = 0$, an intrinsic semiconductor is an insulator.
(*c*) The Fermi energy is the average energy of an electron in a solid.
(*d*) At $T = 0$, the value of the Fermi factor can be either 1 or 0.
(*e*) Semiconductors conduct current in one direction only.
(*f*) The classical free-electron theory adequately explains the heat capacity of metals.
(*g*) The contact potential between two metals is proportional to the difference in the work functions of the two metals.

(*a*) True

(*b*) True

(*c*) False. The Fermi energy is the energy of the last filled (or half-filled) level at $T = 0$.

(*d*) True

(*e*) False

(*f*) False. The classical free-electron theory predicts heat capacities for metals that are not observed experimentally.

(*g*) True

9 • Which of the following elements are most likely to act as acceptor impurities in germanium? (*a*) bromine (*b*) gallium (*c*) silicon (*d*) phosphorus (*e*) magnesium

Determine the Concept Because a gallium atom can accept electrons from the valence band of germanium to complete its four covalent bonds, $\boxed{(b)}$ is correct.

10 • Which of the following elements are most likely to serve as donor impurities in germanium? (*a*) bromine (*b*) gallium (*c*) silicon (*d*) phosphorus (*e*) magnesium

Determine the Concept Because phosphorus has 3 electrons that it can donate to the conduction band of germanium without leaving holes in the valence band, $\boxed{(d)}$ is correct.

11 • An electron hole is created when a photon is absorbed by a semiconductor. How does this hole enable the semiconductor to conduct electricity?

Determine the Concept The excited electron is in the conduction band and can conduct electricity. The positive hole left in the valence band moves through the band and also contributes to the current.

12 • Examine the positions of phosphorus, boron, thallium, and antimony in Table 36-1. (*a*) Which of these elements can be used to dope silicon to create an *n*-type semiconductor? (*b*) Which of these elements can be used to dope silicon to create a *p*-type semiconductor?

Determine the Concept
(a) Phosphorus and antimony will make n-type semiconductors since each has one more valence electron than silicon.

(b) Boron and thallium will make p-type semiconductors since each has one less valence electron than silicon.

13 • When photons of visible light strike the *p*-type semiconductor in a *pn* junction solar cell, (*a*) only free electrons are created, (*b*) only positive holes are created, (*c*) both electrons and holes are created, (*d*) protons are created, (*e*) None of the above.

Determine the Concept Because a *pn* junction solar cell has donor impurities on one side and acceptor impurities on the other, both electrons and holes are created when photons of visible light strike the *p*-type semiconductor cell. $\boxed{(c)}$ is correct.

Estimation and Approximation

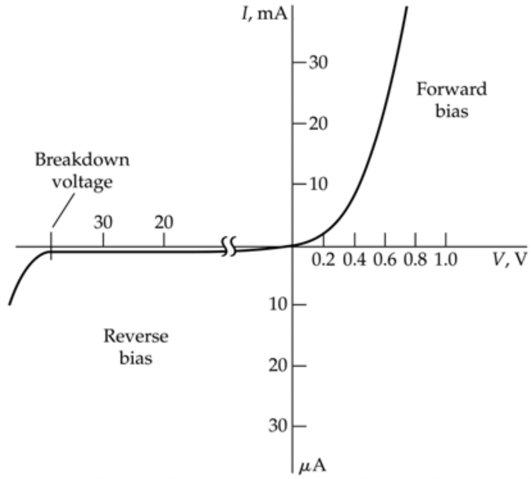
14 • The ratio of the resistivity of the most resistive (least conductive) material to that of the least resistive material (excluding superconductors) is approximately 10^{24}. You can develop a feeling for how remarkable this range is by considering what the ratio is of the largest values to smallest values of other material properties. Choose any three properties of materials, and using tables in this book or some other resource, calculate the ratio of the largest instance of the property to the smallest instance of that property (other than zero) and rank these in decreasing order. Can you find any other property that shows a range as large as that of electrical resistivity?

Picture the Problem We can use the list of tables on the inside back covers of volumes 1 and 2 to find tables of material properties. A representative sample is included in the following table in which all the units are SI:

Table	Material property	Largest value	Smallest value	Ratio (order of magnitude)
13-1	Mass density	22.5×10^{3} (Osmium)	0.08994 (Hydrogen)	10^5
20-3	Thermal conductivity	429 (Ag)	0.026 (air)	10^4
20-1	Thermal expansion	51×10^{-6} (ice)	10^{-6} (invar)	10^2
12-8	Tensile Strength	520 (steel)	2 (concrete)	10^2
12-8	Young's modulus	200 (steel)	9 (bone)	10
18-1	Heat capacity	4.18 (water)	0.900 (Al)	1

15 • A device is said to be "ohmic" if a graph of current versus applied voltage is a straight line through the origin. The resistance R of the device is the reciprocal of the slope of this line. A *pn* junction is an example of a nonohmic device, as may be seen from Figure 38-21. For nonohmic devices, it is sometimes convenient to define the *differential resistance* as the reciprocal of the slope of the I versus V curve. Using the curve in Figure 38-21, estimate the differential resistance of the *pn* junction at applied voltages of –20 V, +0.2 V, +0.4 V, +0.6 V, and +0.8 V.

Picture the Problem Figure 38-21 is reproduced below. We can draw tangent lines at each of the voltages and estimate the slope. The differential resistance is the reciprocal of the slope.



V (V)	1/slope (Ω)
–20	$\boxed{\infty}$
+0.2	$\boxed{40}$
+0.4	$\boxed{20}$
+0.6	$\boxed{10}$
+0.8	$\boxed{5}$

Remarks: Note that, because of the difficulty in determining the slopes, these results are only approximations.

The Structure of Solids

16 • Calculate the center-to-center separation distance r_0 between the K^+ and the Cl^- ions in KCl. Do this by assuming that each ion occupies a cubic volume of side r_0. The molar mass of KCl is 74.55 g/mol and its density is 1.984 g/cm^3.

Picture the Problem We can use the geometry of the ion to relate the volume per mole to the length of its side r_0 and the definition of density to express the volume per mole in terms of its molar mass and density.

Because the cube length/ion is r_0, the volume/mole is given by:

$$V_{\text{mol}} = 2N_{\text{A}}r_0^3 \Rightarrow r_0 = \sqrt[3]{\frac{V_{\text{mol}}}{2N_{\text{A}}}}$$

The volume/mole is given by:

$$V_{\text{mol}} = \frac{M}{\rho}$$

where M is the molar mass of KCl.

Substitute for V_{mol} in the expression for r_0 to obtain:

$$r_0 = \sqrt[3]{\frac{M}{2\rho N_{\text{A}}}}$$

Substitute numerical values and evaluate r_0:

$$r_0 = \sqrt[3]{\frac{74.55\,\text{g/mol}}{2(1.984\,\text{g/cm}^3)(6.022\times10^{23}\ \text{particles/mol})}} = \boxed{0.315\,\text{nm}}$$

17 • The center-to-center separation distance between the Li^+ and Cl^- ions in LiCl is 0.257 nm. Use this value and the molar mass of LiCl (42.4 g/mol) to compute the density of LiCl.

Picture the Problem We can use the definition of density and the geometry of the ions to compute the density of LiCl.

The density of LiCl is given by:

$$\rho = \frac{M_{\text{unit cell}}}{V_{\text{unit cell}}}$$

Express the volume of the unit cell:

$$V_{\text{unit cell}} = (2r_0)^3$$

Because the unit cell has four molecules, its mass is given by:

$$M_{\text{unit cell}} = \frac{4M}{N_{\text{A}}}$$

Substitute for $V_{\text{unit cell}}$ and $M_{\text{unit cell}}$ to obtain:

$$\rho = \frac{\frac{4M}{N_{\text{A}}}}{(2r_0)^3} = \frac{4M}{N_{\text{A}}(2r_0)^3}$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{4(42.4\,\text{g/mol})}{(6.022\times10^{23}\ \text{particles/mol})\left[2(0.257\times10^{-9}\ \text{m})\right]^3} = \boxed{2.07\,\text{g/cm}^3}$$

18 • Find the value of n in Equation 38-6 that gives the measured dissociation energy of 741 kJ/mol for LiCl, which has the same structure as NaCl and for which r_0 = 0.257 nm.

Picture the Problem We can solve Equation 38-6 for n and then substitute numerical values to evaluate n.

Equation 38-6 is:

$$U(r_0) = -\alpha\frac{ke^2}{r_0}\left(1-\frac{1}{n}\right)$$

and

$$|U(r_0)| = \alpha\frac{ke^2}{r_0}\left(1-\frac{1}{n}\right)$$

Solve for *n* to obtain:

$$n = \frac{1}{1-\dfrac{|U(r_0)|r_0}{\alpha ke^2}}$$

Substitute numerical values and evaluate *n*:

$$n = \frac{1}{1 - \dfrac{(741\,\text{kJ/mol})\left(\dfrac{1\text{eV/ion pair}}{96.47\,\text{kJ/mol}}\right)(0.257\,\text{nm})}{(1.7476)(1.44\,\text{eV}\cdot\text{nm})}} = \boxed{4.64}$$

19 •• (*a*) Use Equation 38-6 and calculate $U(r_0)$ for calcium oxide, CaO, where $r_0 = 0.208$ nm. Assume $n = 8$. (*b*) If *n* increase from 8 to 10, what is the fractional change in $U(r_0)$?

Picture the Problem We can substitute numerical values in Equation 38-6 to evaluate $U(r_o)$ for $n = 8$ and $n = 10$.

(*a*) Equation 38-6 is:

$$U(r_0) = -\alpha\frac{ke^2}{r_0}\left(1-\frac{1}{n}\right)$$

Substitute numerical values and evaluate $U(r_0)$:

$$U(r_o) = -\frac{(1.7476)(8.988\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(1.602\times10^{-19}\,\text{C})^2}{(0.208\times10^{-9}\,\text{m})\left(\dfrac{1.602\times10^{-19}\,\text{J}}{1\text{eV}}\right)}\left(1-\frac{1}{8}\right) = \boxed{-10.6\,\text{eV}}$$

(*b*) The fractional change is given by:

$$\frac{\Delta U(r_0)}{U(r_0)} = \frac{U_{n=10} - U_{n=8}}{U_{n=8}} = \frac{U_{n=10}}{U_{n=8}} - 1$$

Substitute numerical values and evaluate $U(r_0)$ for n = 10:

$$U_{n=10}(r_o) = -\frac{(1.7476)\left(8.988\times10^9\ \frac{\mathrm{N\cdot m^2}}{\mathrm{C^2}}\right)\left(1.602\times10^{-19}\ \mathrm{C}\right)^2}{\left(0.208\times10^{-9}\ \mathrm{m}\right)\left(\frac{1.602\times10^{-19}\ \mathrm{J}}{1\mathrm{eV}}\right)}\left(1-\frac{1}{10}\right) = -10.9\,\mathrm{eV}$$

Substitute numerical values and evaluate the fractional change in $U(r_0)$:

$$\frac{\Delta U(r_0)}{U(r_0)} = \frac{-10.9\,\mathrm{eV}}{-10.6\,\mathrm{eV}} - 1 = \boxed{2.83\%}$$

A Microscopic Picture of Conduction

20 • A measure of the density of the free electrons in a metal is the distance r_s, which is defined as the radius of the sphere whose volume equals the volume per conduction electron. (*a*) Show that $r_s = [3/(4\pi n)]^{1/3}$, where n is the free-electron number density. (*b*) Calculate r_s for copper in nanometers.

Picture the Problem We can use the expression for the volume occupied by one electron to show that $r_s = \left(\frac{3}{4\pi n}\right)^{1/3}$.

(*a*) The volume occupied by one electron is:

$$\frac{1}{n} = \frac{4}{3}\pi r_s^3 \Rightarrow r_s = \boxed{\left(\frac{3}{4\pi n}\right)^{1/3}}$$

(*b*) From Table 38-1:

$$n_{\mathrm{Cu}} = 8.47\times10^{28}\ \mathrm{m^{-3}}$$

Substitute numerical values and evaluate r_s for copper:

$$r_s = \sqrt[3]{\frac{3}{4\pi\left(8.47\times10^{28}\ \mathrm{m^{-3}}\right)}} = \boxed{0.141\mathrm{nm}}$$

21 • (*a*) Given a mean free path λ = 0.400 nm and a mean speed $v_{av} = 1.17\times10^5$ m/s for the charge flow in copper at a temperature of 300 K, calculate the classical value for the resistivity ρ of copper. (*b*) The classical model suggests that the mean free path is temperature independent and that v_{av} depends on temperature. According to this model, what would ρ be at 100 K?

Picture the Problem (*a*) We can use the expression for the resistivity of the copper in terms of v_{av} and λ to find the classical value for the resistivity ρ of copper. In Part (*b*) we can use $v_{av} = \sqrt{\frac{3kT}{m_e}}$ to relate the average speed to the temperature.

(*a*) In terms of the mean free path and the mean speed, the resistivity is:

$$\rho = \frac{m_e v_{av}}{n_e e^2 \lambda}$$

Substitute numerical values and evaluate ρ (see Table 38-1 for the free-electron number density of copper):

$$\rho = \frac{(9.109\times10^{-31}\text{ kg})(1.17\times10^{5}\text{ m/s})}{(8.47\times10^{28}\text{ m}^{-3})(1.602\times10^{-19}\text{ C})^2(0.400\,\text{nm})} = \boxed{0.123\,\mu\Omega\cdot\text{m}}$$

(*b*) Relate the average speed of the electrons to the temperature:

$$v_{av} = \sqrt{\frac{3kT}{m_e}}$$

Substitute for v_{av} in the expression for ρ to obtain:

$$\rho = \frac{m_e}{n_e e^2 \lambda}\sqrt{\frac{3kT}{m_e}} = \frac{1}{n_e e^2 \lambda}\sqrt{3m_e kT}$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{\sqrt{3(9.109\times10^{-31}\text{ kg})(1.381\times10^{-23}\text{ J/K})(100\,\text{K})}}{(8.47\times10^{28}\text{ m}^{-3})(1.602\times10^{-19}\text{ C})^2(0.400\,\text{nm})} = \boxed{70.7\,\text{n}\Omega\cdot\text{m}}$$

Free Electrons in a Solid

22 •• Silicon has a molar mass of 28.09 g/mol and a density of 2.41×10^3 kg/m^3. Each atom of silicon has four valence electrons and the Fermi energy of the material is 4.88 eV. (*a*) Given that the electron mean free path at room temperature is l = 27.0 nm, estimate the resistivity. (*b*) The accepted value for the resistivity of silicon is 640 Ω·m (at room temperature). How does this accepted value compare to the value calculated in Part (*a*)?

Picture the Problem We can use Equation 38-14 to estimate the resistivity of silicon.

(*a*) From Equation 38-14:

$$\rho = \frac{m_e v_{av}}{n_e e^2 \lambda}$$

The speed of the electrons is given by:

$$v_{av} = u_F = \sqrt{\frac{2E_F}{m_e}}$$

Substituting for v_{av} yields:

$$\rho = \frac{m_e\sqrt{\dfrac{2E_F}{m_e}}}{n_e e^2 \lambda} = \frac{\sqrt{2m_e E_F}}{n_e e^2 \lambda}$$

The electron density of Si is given by:

$$n_e = MN_A N_{atom}$$

where N_{atom} is the number of electrons per atom.

Substitute for n_e to obtain:

$$\rho = \frac{\sqrt{2m_e E_F}}{MN_A N_{atom} e^2 \lambda}$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{\sqrt{2\left(9.109\times10^{-31}\,\text{kg}\right)\left(4.88\,\text{eV}\right)\left(\dfrac{1.602\times10^{-19}\,\text{J}}{1\,\text{eV}}\right)}}{\left(2.41\times10^{3}\,\dfrac{\text{kg}}{\text{m}^3}\right)\left(\dfrac{6.022\times10^{23}\,\text{atoms}}{0.02809\,\text{kg}}\right)\left(\dfrac{4\,\text{e}}{\text{atom}}\right)\left(1.602\times10^{-19}\,\text{C}\right)^2\left(27.0\times10^{-9}\,\text{m}\right)}$$

$$= \boxed{8.3\,\text{n}\Omega\cdot\text{m}}$$

(*b*) The accepted resistivity of 640 Ω·m is much greater than the calculated value. We assume that valence electrons will produce conduction in the material. Silicon is a semiconductor and a gap between the valence band and conduction band exists. Only electrons with sufficient energies will be found in the conduction band.

23 • Calculate the number density of free electrons in (*a*) Ag (ρ = 10.5 g/cm^3) and (*b*) Au (ρ = 19.3 g/cm^3), assuming one free electron per atom, and compare your results with the values listed in Table 38-1.

Picture the Problem The number density of free electrons is given by $n = \rho N_A / M$, where N_A is Avogadro's number, ρ is the density of the element, and M is its molar mass.

Relate the number density of free electrons to the density ρ and molar mass M of the element:

$$\frac{n}{N_A} = \frac{\rho}{M} \Rightarrow n = \frac{\rho N_A}{M}$$

(*a*) For Ag:

$$n_{\text{Ag}} = \frac{\left(10.5\,\text{g/cm}^3\right)\left(6.022\times10^{23}\text{ electrons/mol}\right)}{107.87\,\text{g/mol}} = \boxed{5.86\times10^{22}\text{ electrons/cm}^3}$$

(*b*) For Au:

$$n_{\text{Ag}} = \frac{\left(19.3\,\text{g/cm}^3\right)\left(6.022\times10^{23}\text{ electrons/mol}\right)}{196.97\,\text{g/mol}} = \boxed{5.90\times10^{22}\text{ electrons/cm}^3}$$

Both these results agree with the values in Table 38-1.

24 • The density of aluminum is 2.7 g/cm^3. How many free electrons are present per aluminum atom?

Picture the Problem The number of free electrons per atom n_e is given by $n_e = nM/\rho N_A$, where N_A is Avogadro's number, ρ is the density of the element, M is its molar mass, and n is the free electron number density for the element.

The number of free electrons per atom is given by:

$$n_e = \frac{nM}{\rho N_A}$$

Substitute numerical values and evaluate n_e:

$$n_e = \frac{\left(18.1\times10^{22}\text{ electrons/cm}^3\right)\left(26.98\,\text{g/mol}\right)}{\left(2.7\,\text{g/cm}^3\right)\left(6.022\times10^{23}\text{ electrons/mol}\right)} = \boxed{3.0}$$

25 • The density of tin is 7.3 g/cm^3. How many free electrons are present per tin atom?

Picture the Problem The number of free electrons per atom n_e is given by $n_e = nM/\rho N_A$, where N_A is Avogadro's number, ρ is the density of the element, M is its molar mass, and n is the free electron number density for the element.

The number of free electrons per atom is given by:

$$n_e = \frac{nM}{\rho N_A}$$

Substitute numerical values and evaluate n_e:

$$n_e = \frac{\left(14.8\times10^{22}\ \text{electrons/cm}^3\right)\left(118.69\ \text{g/mol}\right)}{\left(7.3\ \text{g/cm}^3\right)\left(6.022\times10^{23}\ \text{electrons/mol}\right)} = \boxed{4.0}$$

26 • Calculate the Fermi temperature for (*a*) Mg, (*b*) Mn, and (*c*) Zn.

Picture the Problem The Fermi temperature T_F is defined by $kT_F = E_F$, where E_F is the Fermi energy. See Table 38-1 for Fermi energies at $T = 0$.

The Fermi temperature is given by:

$$T_F = \frac{E_F}{k}$$

(*a*) For Mg:

$$T_F = \frac{7.11\ \text{eV}}{8.617\times10^{-5}\ \text{eV/K}} = \boxed{8.25\times10^{4}\ \text{K}}$$

(*b*) For Mn:

$$T_F = \frac{11.0\ \text{eV}}{8.617\times10^{-5}\ \text{eV/K}} = \boxed{1.28\times10^{5}\ \text{K}}$$

(*c*) For Zn:

$$T_F = \frac{9.46\ \text{eV}}{8.617\times10^{-5}\ \text{eV/K}} = \boxed{1.10\times10^{5}\ \text{K}}$$

27 • What is the speed of a conduction electron whose energy is equal to the Fermi energy E_F for (*a*) Na, (*b*) Au, and (*c*) Sn?

Picture the Problem We can solve the expression for the Fermi energy for the speed of a conduction electron.

Express the Fermi energy in terms of the Fermi speed of a conduction electron:

$$E_F = \tfrac{1}{2} m_e u_F^2 \Rightarrow u_F = \sqrt{\frac{2E_F}{m_e}}$$

(*a*) Substitute numerical values (see Table 38-1 for E_F) and evaluate u_F for Na:

$$u_F = \sqrt{\frac{2\left(3.24\ \text{eV}\right)\left(1.602\times10^{-19}\ \text{J/eV}\right)}{9.109\times10^{-31}\ \text{kg}}} = \boxed{1.07\times10^{6}\ \text{m/s}}$$

(*b*) Substitute numerical values and evaluate u_F for Au:

$$u_F = \sqrt{\frac{2(5.53\,\text{eV})(1.602\times10^{-19}\ \text{J/eV})}{9.109\times10^{-31}\ \text{kg}}} = \boxed{1.39\times10^{6}\ \text{m/s}}$$

(*c*) Substitute numerical values and evaluate u_F for Sn:

$$u_F = \sqrt{\frac{2(10.2\,\text{eV})(1.602\times10^{-19}\ \text{J/eV})}{9.109\times10^{-31}\ \text{kg}}} = \boxed{1.89\times10^{6}\ \text{m/s}}$$

28 • Calculate the Fermi energy for (*a*) Al, (*b*) K, and (*c*) Sn using the number densities given in Table 38-1.

Picture the Problem The Fermi energy at $T = 0$ depends on the number of electrons per unit volume (the number density) according to $E_F = (0.365\,\text{eV}\cdot\text{nm}^2)(N/V)^{2/3}$.

The Fermi energy at $T = 0$ is given by:

$$E_F = (0.365\,\text{eV}\cdot\text{nm}^2)\left(\frac{N}{V}\right)^{2/3}$$

(*a*) For Al, $N/V = 18.1\times10^{22}$ electrons/cm^3 (see Table 38-1) and:

$$E_F = (0.365\,\text{eV}\cdot\text{nm}^2)(18.1\times10^{22}\ \text{electrons/cm}^3)^{2/3} = \boxed{11.7\,\text{eV}}$$

(*b*) For K, $N/V = 1.40 \times 10^{22}$ electrons/cm^3 and:

$$E_F = (0.365\,\text{eV}\cdot\text{nm}^2)(1.40\times10^{22}\ \text{electrons/cm}^3)^{2/3} = \boxed{2.12\,\text{eV}}$$

(*c*) For Sn, $N/V = 14.8\times10^{22}$ electrons/cm^3 and:

$$E_F = (0.365\,\text{eV}\cdot\text{nm}^2)(14.8\times10^{22}\ \text{electrons/cm}^3)^{2/3} = \boxed{10.2\,\text{eV}}$$

29 • Find the average energy of the conduction electrons at $T = 0$ in (*a*) copper and (*b*) lithium.

Picture the Problem The average energy of electrons in a Fermi gas at $T = 0$ is three-fifths of the Fermi energy.

The average energy at $T = 0$ is given by:

$$E_{av} = \tfrac{3}{5}E_F$$

(*a*) For copper, $E_F = 7.04$ eV (see Table 38-1) and:

$$E_{av} = \tfrac{3}{5}(7.04\,\text{eV}) = \boxed{4.22\,\text{eV}}$$

(*b*) For lithium, $E_F = 4.75$ eV and:

$$E_{av} = \tfrac{3}{5}(4.75\,\text{eV}) = \boxed{2.85\,\text{eV}}$$

30 • Calculate (*a*) the Fermi temperature and (*b*) the Fermi energy at $T = 0$ for iron.

Picture the Problem The Fermi energy at $T = 0$ is given by $E_F = (0.365\,\text{eV}\cdot\text{nm}^2)(N/V)^{3/2}$, where N/V is the free-electron number density and the Fermi temperature is related to the Fermi energy according to $kT_F = E_F$.

(*a*) The Fermi temperature for iron is given by:

$$T_F = \frac{E_F}{k}$$

Substitute numerical values (see Table 38-1) and evaluate T_F:

$$T_F = \frac{11.2\,\text{eV}}{8.617\times10^{-5}\,\text{eV/K}} = \boxed{1.30\times10^{5}\,\text{K}}$$

(*b*) The Fermi energy at $T = 0$ is given by:

$$E_F = (0.365\,\text{eV}\cdot\text{nm}^2)\left(\frac{N}{V}\right)^{3/2}$$

Substitute numerical values (see Table 38-1) and evaluate E_F:

$$E_F = (0.365\,\text{eV}\cdot\text{nm}^2)(17.0\times10^{22}\,\text{electrons/cm}^3)^{2/3} = \boxed{11.2\,\text{eV}}$$

31 •• **[SSM]** (*a*) Assuming that each gold atom in a sample of gold metal contributes one free electron, calculate the free-electron density in gold knowing that its atomic mass is 196.97 g/mol and its density is 19.3×10^3 kg/m^3. (*b*) If the Fermi speed for gold is 1.39×10^6 m/s, what is the Fermi energy in electron volts? (*c*) By what factor is the Fermi energy higher than the kT energy at room temperature? (*d*) Explain the difference between the Fermi energy and the kT energy.

Picture the Problem We can use $n_e = \rho V = \dfrac{\rho N_A N_{atom}}{m}$, where N_{atom} is the number of electrons per atom, to calculate the electron density of gold. The Fermi energy is given by $E_F = \tfrac{1}{2}m_e u_F^2$.

(*a*) The electron density of gold is given by:

$$n_e = \rho V = \frac{\rho N_A N_{atom}}{m}$$

Substitute numerical values and evaluate n_e:

$$n_e = \frac{\left(19.3\times10^3\ \frac{\text{kg}}{\text{m}^3}\right)\left(6.022\times10^{23}\,\text{atoms}\right)\left(\frac{1\text{e}}{1\,\text{atom}}\right)}{0.197\ \text{kg}} = \boxed{5.90\times10^{28}\ \text{e/m}^3}$$

(*b*) The Fermi energy is given by:

$$E_F = \tfrac{1}{2} m_e u_F^2$$

Substitute numerical values and evaluate E_F:

$$E_F = \frac{1}{2}\left(9.109\times10^{-31}\,\text{kg}\right)\left(1.39\times10^6\,\text{m/s}\right)^2\left(\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\right) = \boxed{5.50\,\text{eV}}$$

(*c*) The factor by which the Fermi energy is higher than the kT energy at room temperature is:

$$f = \frac{E_F}{kT}$$

At room temperature $kT = 0.026$ eV. Substitute numerical values and evaluate f:

$$f = \frac{5.50\ \text{eV}}{0.026\ \text{eV}} = \boxed{212}$$

(*d*) The ratio E_F/kT is equal to 212 $T = 300$ K. The Fermi energy is the energy of the most energetic conduction electron when the crystal is at absolute zero. Because no two conduction electrons can occupy the same state, the Fermi energy is quite high compared with kT. The kT energy is the energy the average conduction electron would have when the crystal is at temperature T if the electrons did not obey the exclusion principle.

32 •• The bulk modulus B of a material can be defined by $B = -V\,\partial P/\partial V$. (*a*) Use the monatomic ideal-gas relation $PV = \tfrac{2}{3} N E_{av}$, where E_{av} is the average kinetic energy, Equation 38-22 and Equation 38-23 to show that $P = \tfrac{2}{5} N E_F / V = C V^{-5/3}$, where C is a constant independent of V. (*b*) Show that the bulk modulus of the free electrons in a solid metal is therefore $B = \tfrac{5}{3} P = \tfrac{2}{3} N E_F / V$. (*c*) Compute the bulk modulus in newtons per square meter for the free electrons in a sample of copper and compare your result with the measured value of 140×10^9 N/m^2.

Picture the Problem We can follow the procedure given in the problem statement to show that $P = \dfrac{2NE_F}{5V} = CV^{-5/3}$ and $B = \dfrac{5}{3}P = \dfrac{2NE_F}{3V}$.

(a) We're given that, for a monatomic ideal-gas:

$$PV = \tfrac{2}{3}NE_{\text{av}}$$

Because $E_{\text{av}} = \tfrac{3}{5}E_{\text{F}}$:

$$P = \frac{2}{3}\left(\frac{N}{V}\right)\left(\frac{3}{5}E_{\text{F}}\right) = \frac{2}{5}\left(\frac{N}{V}\right)E_{\text{F}} \qquad (1)$$

The Fermi energy is given by:

$$E_{\text{F}} = \frac{h^2}{8m_{\text{e}}}\left(\frac{3N}{\pi V}\right)^{2/3} = \frac{h^2}{8m_{\text{e}}}\left(\frac{3N}{\pi}\right)^{2/3} V^{-2/3}$$

Substitute to obtain:

$$P = \frac{2}{5}\left(\frac{N}{V}\right)\frac{h^2}{8m_{\text{e}}}\left(\frac{3N}{\pi}\right)^{2/3} V^{-2/3}$$

$$= \frac{N^{5/3}h^2}{20m_{\text{e}}}\left(\frac{3}{\pi}\right)^{2/3} V^{-5/3} = \boxed{CV^{-5/3}}$$

where $C = \dfrac{N^{5/3}h^2}{20m_{\text{e}}}\left(\dfrac{3}{\pi}\right)^{2/3}$ is a constant.

(b) The bulk modulus is given by:

$$B = -V\frac{dP}{dV} = -V\frac{d}{dV}\left[CV^{-5/3}\right]$$

$$= -CV\left(-\frac{5}{3}V^{-8/3}\right) = \frac{5}{3}CV^{-5/3}$$

$$= \frac{5}{3}P$$

Substitute for P from equation (1) to obtain:

$$B = \frac{5}{3}\left[\frac{2}{5}\left(\frac{N}{V}\right)E_{\text{F}}\right] = \boxed{\tfrac{2}{3}NE_{\text{F}}/V}$$

(c) Substitute numerical values and evaluate B for copper:

$$B = \frac{2}{3}\left(8.47\times10^{22}\text{ electrons/cm}^3\right)\left(7.04\,\text{eV}\right)\left(1.602\times10^{-19}\text{ J/eV}\right) = \boxed{63.6\text{ GN/m}^2}$$

From Table 13-2:

$$B_{\text{Cu}} = 140\text{ GN/m}^2$$

Divide the calculated value for B by the value from Table 13-2 to obtain:

$$\frac{B}{B_{\text{Cu}}} = \frac{63.6\,\text{GN/m}^2}{140\,\text{GN/m}^2} = 0.454$$

or

$$B = \boxed{0.454B_{\text{Cu}}}$$

33 •• [SSM] The pressure of a monatomic ideal gas is related to the average kinetic energy of the gas particles by $PV = \frac{2}{3}NE_{av}$, where N is the number of particles and E_{av} is the average kinetic energy. Use this information to calculate the pressure of the free electrons in a sample of copper in newtons per square meter, and compare your result with atmospheric pressure, which is about 10^5 N/m^2. (Note: The units are most easily handled by using the conversion factors 1 N/m^2 = 1 J/m^3 and 1 eV = 1.602×10^{-19} J.)

Picture the Problem We can solve $PV = \frac{2}{3}NE_{av}$ for P and substitute for E_{av} in order to express P in terms of N/V and E_F.

Solve $PV = \frac{2}{3}NE_{av}$ for P:

$$P = \frac{2}{3}\left(\frac{N}{V}\right)E_{av}$$

Because $E_{av} = \frac{3}{5}E_F$:

$$P = \frac{2}{3}\left(\frac{N}{V}\right)\left(\frac{3}{5}E_F\right) = \frac{2}{5}\left(\frac{N}{V}\right)E_F$$

Substitute numerical values (see Table 38-1) and evaluate P:

$$P = \frac{2}{5}\left(8.47\times10^{22}\ \text{electrons/cm}^3\right)\left(7.04\,\text{eV}\right)\left(1.602\times10^{-19}\ \text{J/eV}\right)$$

$$= \boxed{3.82\times10^{10}\ \text{N/m}^2} = 3.82\times10^{10}\ \text{N/m}^2 \times \frac{1\,\text{atm}}{101.325\times10^3\ \text{N/m}^2}$$

$$= \boxed{3.77\times10^5\,\text{atm}}$$

34 • Calculate the contact potential between (*a*) Ag and Cu, (*b*) Ag and Ni, and (*c*) Ca and Cu.

Picture the Problem The contact potential is given by $V_{contact} = \frac{\phi_1 - \phi_2}{e}$, where ϕ_1 and ϕ_2 are the work functions of the two different metals in contact with each other.

The contact potential is given by:

$$V_{contact} = \frac{\phi_1 - \phi_2}{e}$$

(*a*) For Ag and Cu (see Table 38-1):

$$V_{contact} = \frac{4.7\,\text{eV} - 4.1\,\text{eV}}{e} = \boxed{0.6\,\text{V}}$$

(*b*) For Ag and Ni:

$$V_{contact} = \frac{5.2\,\text{eV} - 4.7\,\text{eV}}{e} = \boxed{0.5\,\text{V}}$$

(*c*) For Ca and Cu (see Table 38-1):

$$V_{\text{contact}} = \frac{4.1\,\text{eV} - 3.2\,\text{eV}}{e} = \boxed{0.9\,\text{V}}$$

Heat Capacity Due to Electrons in a Metal

35 •• [SSM] Gold has a Fermi energy of 5.53 eV. Determine the molar specific heat at constant volume at room temperature for gold.

Picture the Problem We can use Equation 38-29 to find the molar specific heat of gold at constant volume and room temperature.

The molar specific heat is given by Equation 38-29:

$$c'_{\text{V}} = \frac{\pi^2 RT}{2T_{\text{F}}}$$

The Fermi energy is given by:

$$E_{\text{F}} = kT_{\text{F}} \Rightarrow T_{\text{F}} = \frac{E_{\text{F}}}{k}$$

Substitute for T_{F} to obtain:

$$c'_{\text{V}} = \frac{\pi^2 RkT}{2E_{\text{F}}}$$

Substitute numerical values and evaluate c'_{V}:

$$c'_{\text{V}} = \frac{\pi^2 (8.314\,\text{J/mol K})(1.381\times10^{-23}\,\text{J/mol})\left(\dfrac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\right)(300\,\text{K})}{2(5.53\,\text{eV})}$$

$$= \boxed{0.192\,\text{J/mol}\cdot\text{K}}$$

Remarks: The value 0.192 J/mol K is for a mole of gold atoms. Because each gold atom contributes one electron to the metal, a mole of gold corresponds to a mole of electrons.

Quantum Theory of Electrical Conduction

36 • The resistivities and Fermi speeds of Na, Au, and Sn at T = 273 K are 4.2 $\mu\Omega$·cm, 2.04 $\mu\Omega$·cm and 10.6 $\mu\Omega$·cm, and 1.07×10^6 m/s, 1.39×10^6 m/s and 1.89×10^6 m/s respectively. Use these values to find the mean free paths for the conduction electrons in these elements.

Picture the Problem We can solve the equation giving the resistivity of a conductor in terms of the mean free path and the mean speed for the mean free path and use the Fermi speeds as the mean speeds.

In terms of the mean free path and the mean speed, the resistivity is:

$$\rho = \frac{m_e v_{av}}{ne^2\lambda} \Rightarrow \lambda = \frac{m_e v_{av}}{ne^2\rho}$$

Using the Fermi speeds as the average speeds, substitute numerical values and evaluate the mean free path of Na:

$$\lambda_{Na} = \frac{(9.109\times10^{-31}\ \text{kg})(1.07\times10^{6}\ \text{m/s})}{(2.65\times10^{22}\ \text{electrons/cm}^3)(1.602\times10^{-19}\ \text{C})^2(4.2\ \mu\Omega\cdot\text{cm})} = \boxed{34\,\text{nm}}$$

Proceed as above for Au:

$$\lambda_{Au} = \frac{(9.109\times10^{-31}\ \text{kg})(1.39\times10^{6}\ \text{m/s})}{(5.90\times10^{22}\ \text{electrons/cm}^3)(1.602\times10^{-19}\ \text{C})^2(2.04\ \mu\Omega\cdot\text{cm})} = \boxed{41.1\,\text{nm}}$$

Proceed as above for Sn:

$$\lambda_{Sn} = \frac{(9.109\times10^{-31}\ \text{kg})(1.89\times10^{6}\ \text{m/s})}{(14.8\times10^{22}\ \text{electrons/cm}^3)(1.602\times10^{-19}\ \text{C})^2(10.6\ \mu\Omega\cdot\text{cm})} = \boxed{4.29\,\text{nm}}$$

37 •• [SSM] The resistivity of pure copper increases by approximately $1.0 \times 10^{-8}\ \Omega\cdot\text{m}$ with the addition of 1.0 percent (by number of atoms) of an impurity distributed throughout the metal. The mean free path λ depends on both the impurity and the oscillations of the lattice ions according to the equation $1/\lambda = 1/\lambda_t + 1/\lambda_i$, where λ_t is the mean free path associated with the thermal vibrations of the ions and λ_i is the mean free path associated with the impurities. (*a*) Estimate λ_i using Equation 38-14 and the data given in Table 38-1. (*b*) If *r* is the effective radius of an impurity lattice ion seen by an electron, the scattering cross section is πr^2. Estimate this area, using the fact that *r* is related to λ_i by Equation 38-16.

Picture the Problem We can solve the resistivity equation for the mean free path and then substitute the Fermi speed for the average speed to express the mean free path as a function of the Fermi energy.

(*a*) In terms of the mean free path and the mean speed, the resistivity is:

$$\rho_i = \frac{m_e v_{av}}{ne^2\lambda_i} = \frac{m_e u_F}{ne^2\lambda_i} \Rightarrow \lambda_i = \frac{m_e u_F}{ne^2\rho_i}$$

Express the Fermi speed u_F in terms of the Fermi energy E_F:

$$u_F = \sqrt{\frac{2E_F}{m_e}}$$

Substitute for u_F and simplify to obtain:

$$\lambda_i = \frac{\sqrt{2m_e E_F}}{ne^2\rho_i}$$

Substitute numerical values (see Table 38-1) and evaluate λ_i:

$$\lambda_i = \frac{\sqrt{2\left(9.109\times10^{-31}\text{ kg}\right)\left(7.04\,\text{eV}\right)\left(1.602\times10^{-19}\text{ J/eV}\right)}}{\left(8.47\times10^{28}\text{ electrons/m}^3\right)\left(1.602\times10^{-19}\text{ C}\right)^2\left(1.0\times10^{-8}\ \Omega\cdot\text{m}\right)} = 66.1\,\text{nm}$$
$$= \boxed{66\,\text{nm}}$$

(*b*) From Equation 38-16 we have:

$$\lambda = \frac{1}{n\pi r^2} \Rightarrow \pi r^2 = \frac{1}{n\lambda}$$

Substitute numerical values and evaluate πr^2:

$$\pi r^2 = \frac{1}{\left(8.47\times10^{28}\text{ m}^{-3}\right)\left(66.1\text{nm}\right)}$$
$$= \boxed{1.8\times10^{-4}\text{ nm}^2}$$

Band Theory of Solids

38 • Electromagnetic radiation is incident on the surface of a semiconductor. The maximum wavelength of this light that is required if electrons are to cross the energy gap between the valence band and the conduction band is 380.0 nm. What is the energy gap, in electron volts, for this semiconductor?

Picture the Problem We can use $E_g = hc/\lambda$ to calculate the energy gap for this semiconductor.

The lowest photon energy to increase conductivity is given by:

$$E_g = \frac{hc}{\lambda}$$

Substitute numerical values and evaluate E_g:

$$E_g = \frac{\left(6.626\times10^{-34}\,\text{J}\cdot\text{s}\right)\left(2.998\times10^{8}\,\text{m/s}\right)}{\left(380.0\times10^{-9}\,\text{m}\right)\left(1.602\times10^{-19}\,\text{J/eV}\right)}$$
$$= \boxed{3.26\,\text{eV}}$$

39 • **[SSM]** An electron occupies the highest energy level of the valence band in a silicon sample. What is the maximum photon wavelength that will excite the electron across the energy gap if the gap is 1.14 eV?

Picture the Problem We can relate the maximum photon wavelength to the energy gag using $\Delta E = hf = hc/\lambda$.

Express the energy gap as a function of the wavelength of the photon:

$$\Delta E = hf = \frac{hc}{\lambda} \Rightarrow \lambda = \frac{hc}{\Delta E}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{1.14\,\text{eV}} = \boxed{1.09\,\mu\text{m}}$$

40 • An electron occupies the highest energy level of the valence band in a germanium sample. What is the maximum photon wavelength that will excite the electron into the conduction band? In germanium, the energy gap between the valence and conduction bands is 0.74 eV.

Picture the Problem We can relate the maximum photon wavelength to the energy gag using $\Delta E = hf = hc/\lambda$.

Express the energy gap as a function of the wavelength of the photon:

$$\Delta E = hf = \frac{hc}{\lambda} \Rightarrow \lambda = \frac{hc}{\Delta E}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{0.74\,\text{eV}} = \boxed{1.7\,\mu\text{m}}$$

41 • An electron occupies the highest energy level of the valence band in a diamond sample. What is the maximum photon wavelength that will excite the electron into the conduction band? In diamond, the energy gap between the valence and conduction bands is 7.0 eV.

Picture the Problem We can relate the maximum photon wavelength to the energy gag using $\Delta E = hf = hc/\lambda$.

Express the energy gap as a function of the wavelength of the photon:

$$\Delta E = hf = \frac{hc}{\lambda} \Rightarrow \lambda = \frac{hc}{\Delta E}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{7.0\,\text{eV}} = \boxed{180\,\text{nm}}$$

42 •• A photon of wavelength 3.35 μm has just enough energy to raise an electron from the valence band to the conduction band in a lead sulfide sample. (*a*) Find the energy gap between these bands in lead sulfide. (*b*) Find the temperature T for which kT equals this energy gap.

Picture the Problem We can use $\Delta E = hf = hc/\lambda$ to find the energy gap between these bands and $T = E_g/k$ to find the temperature for which kT equals this energy gap.

(*a*) Express the energy gap as a function of the wavelength of the photon:

$$\Delta E = \frac{hc}{\lambda}$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = \frac{1240\,\text{eV}\cdot\text{nm}}{3.35\,\mu\text{m}} = 0.3701\,\text{eV} = \boxed{0.370\,\text{eV}}$$

(*b*) The temperature is related to the energy gap E_g according to:

$$T = \frac{E_g}{k}$$

Substitute numerical values and evaluate T:

$$T = \frac{0.3701\,\text{eV}}{8.617\times10^{-5}\,\text{eV/K}} = \boxed{4.29\times10^{3}\,\text{K}}$$

Semiconductors

43 • The donor energy levels in an *n*-type semiconductor are 0.0100 eV below the conduction band. Find the temperature for which kT = 0.0100 eV.

Picture the Problem We can use $\Delta E = kT$ to find the temperature for which kT = 0.0100 eV

Express the temperature T in terms of the energy gap ΔE:

$$T = \frac{\Delta E}{k}$$

Substitute numerical values and evaluate T:

$$T = \frac{0.0100\,\text{eV}}{1.381\times10^{-23}\,\text{J/K}\times\dfrac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}} = \boxed{116\,\text{K}}$$

44 •• When a thin slab of semiconducting material is illuminated with monochromatic electromagnetic radiation, most of the radiation is transmitted through the slab if the wavelength is greater than 1.85 mm. For wavelengths less than 1.85 mm, most of the incident radiation is absorbed. Determine the energy gap of this semiconductor.

Picture the Problem We can use $E = hf$ to find the energy gap of this semiconductor.

The energy gap of the semiconductor is given by:

$$E_g = hf = \frac{hc}{\lambda} \text{ where } hc = 1240 \text{ eV}\cdot\text{nm}$$

Substitute numerical values and evaluate E_g:

$$E_g = \frac{1240\,\text{eV}\cdot\text{nm}}{1.85\,\mu\text{m}} = \boxed{0.670\,\text{eV}}$$

45 •• The relative binding of the extra electron in the arsenic atom that replaces an atom in silicon or germanium can be understood from a calculation of the first Bohr radius of this electron in these materials. Four of arsenic's valence electrons form covalent bonds, so the fifth electron sees a center of attraction with a charge of $+e$. This model is a modified hydrogen atom. In the Bohr model of the hydrogen atom, the electron moves in free space at a radius a_0 given by $a_0 = 4\pi \in_0 \hbar^2/(m_e e^2)$ (Equation 36-12). When an electron moves in a crystal, we can approximate the effect of the other atoms by replacing $\in_0$ with $\kappa \in_0$ and m_e with an effective mass for the electron. For silicon, κ is 12 and the effective mass is approximately $0.2m_e$. For germanium, κ is 16 and the effective mass is approximately $0.1m_e$. Estimate the Bohr radii for the valence electron as it orbits the impurity arsenic atom in silicon and germanium.

Picture the Problem We can make the indicated substitutions in the expression for a_0 (= 0.0529 nm) to obtain an expression for the Bohr radii for the outer electron as it orbits the impurity arsenic atom in silicon and germanium.

Make the indicated substitutions in the expression for a_0 to obtain:

$$a_B = \frac{\kappa \in_0 h^2}{\pi\, m_{eff} e^2} = \frac{\kappa \in_0 m_e h^2}{\pi\, m_e m_{eff} e^2} = \frac{\kappa m_e}{m_{eff}} \frac{\in_0 h^2}{\pi\, m_e e^2} = \frac{\kappa m_e}{m_{eff}} a_0$$

For silicon:

$$a_{B,Si} = \frac{12m_e}{0.2m_e}(0.0529\,\text{nm}) = \boxed{3\,\text{nm}}$$

For germanium:

$$a_{B,Ge} = \frac{16m_e}{0.1m_e}(0.0529\,\text{nm}) = \boxed{8\,\text{nm}}$$

46 •• The ground-state energy of the hydrogen atom is given by $E_1 = -m_e e^4 / \left(8 \in_0^2 h^2\right)$ (Equation 36-15 and 36-16 where $4\pi\in_0$ is substituted for k^{-1}). Modify this equation using information in Problem 45 by replacing $\in_0$ with $\kappa\in_0$ and m_e with an effective mass for the electron to estimate the binding energy of the extra electron of an impurity arsenic atom in (*a*) silicon and (*b*) germanium.

Picture the Problem We can make the same substitutions we made in Problem 45 in the expression for E_1 (= 13.6 eV) to obtain an expression that we can use to estimate the binding energy of the extra electron of an impurity arsenic atom in silicon and germanium.

Make the indicated substitutions in the expression for E_1 to obtain:

$$E_{\text{binding}} = -\frac{e^4 m_{\text{eff}}}{8(\kappa \in_0)^2 h^2} = -\frac{e^4 m_e m_{\text{eff}}}{8 m_e \kappa^2 \in_0^2 h^2}$$
$$= -\frac{m_{\text{eff}}}{m_e \kappa^2 \in_0^2} \frac{e^4 m_e}{8 \in_0^2 h^2}$$
$$= -\frac{m_{\text{eff}}}{m_e \kappa^2 \in_0^2} E_1$$

(*a*) For silicon:

$$E_{\text{binding}} = -\frac{0.2 m_e}{m_e (12)^2}(13.6\,\text{eV})$$
$$= \boxed{-0.02\,\text{eV}}$$

(*b*) For germanium:

$$E_{\text{binding}} = -\frac{0.1 m_e}{m_e (16)^2}(13.6\,\text{eV})$$
$$= \boxed{-0.05\,\text{eV}}$$

47 •• A doped *n*-type silicon sample has 1.00×10^{16} electrons per cubic centimeter in the conduction band and has a resistivity of 5.00×10^{23} Ω·m at 300 K. Find the mean free path of the electrons. Use the effective mass of $0.2m_e$ for the mass of the electrons. (See Problem 45.) Compare this mean free path with that of conduction electrons in copper at 300 K.

Picture the Problem We can use the expression for the resistivity ρ of the sample as a function of the mean free path λ of the conduction electrons in conjunction with the expression for the average speed v_{av} of the electrons to derive an expression that we can use to calculate the mean free path of the electrons.

Express the resistivity ρ of the sample as a function of the mean free path λ of the conduction electrons:

$$\rho = \frac{m_e v_{av}}{n_e e^2 \lambda} \Rightarrow \lambda = \frac{m_e v_{av}}{n_e e^2 \rho} \qquad (1)$$

The average speed v_{av} of the electrons is given by:

$$v_{av} \approx v_{rms} = \sqrt{\frac{3kT}{m_e}}$$

Substitute for v_{av} in the expression for λ and simplify to obtain:

$$\lambda = \frac{m_e}{n_e e^2 \rho}\sqrt{\frac{3kT}{m_e}} = \frac{\sqrt{3km_eT}}{n_e e^2 \rho}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{\sqrt{3(1.381\times10^{-23}\text{ J/K})(0.2)(9.109\times10^{-31}\text{ kg})(300\text{ K})}}{(10^{16}\text{ cm}^{-3})(1.602\times10^{-19}\text{ C})^2(5.00\times10^{-3}\ \Omega\cdot\text{m})} = \boxed{37.1\text{ nm}}$$

The number density of electrons n_e is related to the mass density ρ_m, Avogadro's number N_A, and the molar mass M.:

$$n_e = \frac{\rho_m N_A}{M}$$

Substitute numerical values (For copper, ρ = 8.93 g/cm^3 and M = 63.5 g/mol.) and evaluate n_e:

$$n_e = \frac{(8.93\text{ g/cm}^3)(6.022\times10^{23}\text{ electrons/mol})}{63.5\text{ g/mol}} = 8.47\times10^{28}\text{ electrons/m}^3$$

Using equation (1), evaluate λ_{Cu} (see Table 25-1 for the resistivity of copper and Example 38-5 for u_F):

$$\lambda_{Cu} = \frac{(9.109\times10^{-31}\text{ kg})(1.57\times10^{6}\text{ m/s})}{(8.47\times10^{28}\text{ electrons/m}^3)(1.602\times10^{-19}\text{ C})^2(1.70\times10^{-8}\ \Omega\cdot\text{m})} = \boxed{38.7\text{ nm}}$$

The mean free paths agree to within about 4%.

48 ••• In the Hall effect, the Hall coefficient R_H is the proportionality constant between the transverse electric field and the product of the applied magnetic field and the current density. That is, $E_y = R_H B_z J_x$, where the current density, the transverse electric field and the applied magnetic field are in the +x, +y and +z directions, respectively. (The Hall effect is presented in Chapter 26.) The measured Hall coefficient of a doped silicon sample is 0.0400 V·m/(A·T) at room temperature. If all the doping impurities have contributed to the total number of charge carriers of the sample, find (a) the type of impurity (donor or acceptor) used to dope the sample and (b) the concentration of these impurities.

Picture the Problem We can use the definition of the Hall electric field in the slab, the expression for the Hall voltage across it, and the definition of current density to show that the Hall coefficient is given by 1/(*nq*). We can use the expression for the Hall coefficient to determine the type of impurity and the concentration of these impurities.

(*a*) The Hall coefficient is:

$$R=\frac{E_y}{J_xB_z}$$

where J_x is *x* component of the current density in the material, B_z is the *z* component of the magnetic field, and E_y is the *y* component resulting Hall electric field.

Using its definition, express the Hall electric field in the slab:

$$E_y=\frac{V_\mathrm{H}}{w}$$

The current density in the slab is:

$$J_x=\frac{I}{wt}=nqv_\mathrm{d}$$

Substitute for E_y and J_x and simplify to obtain:

$$R=\frac{\frac{V_\mathrm{H}}{w}}{nqv_\mathrm{d}B_z}=\frac{V_\mathrm{H}}{nqv_\mathrm{d}wB_z}$$

Express the Hall voltage in terms of v_d, *B*, and *w*:

$$V_\mathrm{H}=v_\mathrm{d}B_zw$$

Substitute for V_H and simplify to obtain:

$$R=\frac{v_\mathrm{d}B_zw}{nqv_\mathrm{d}wB_z}=\frac{1}{nq} \qquad (1)$$

Because $R > 0$, $q > 0$ and conduction is by holes and the sample contains acceptor impurities.

(*b*) Solve equation (1) for *n*:

$$n=\frac{1}{Rq}$$

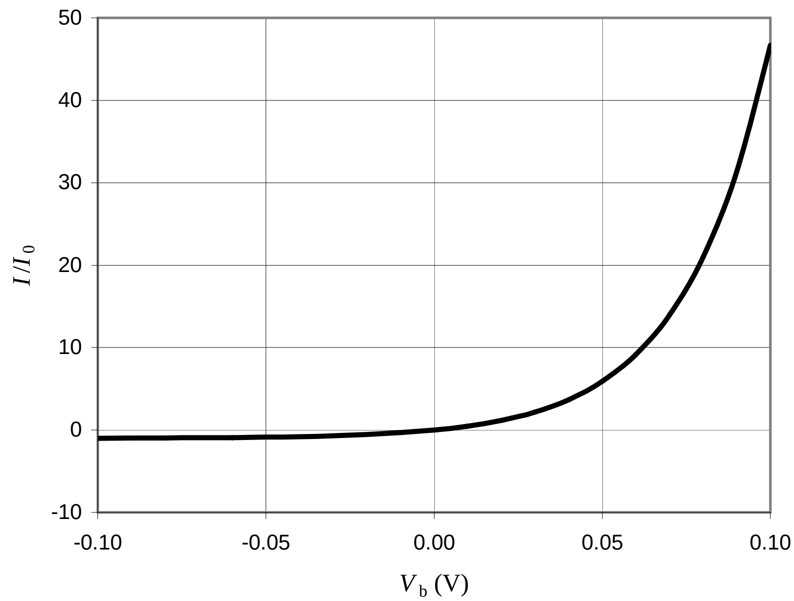
Substitute numerical values and evaluate *n*:

$$n=\frac{1}{(0.0400\,\mathrm{V\cdot m/A\cdot T})(1.602\times10^{-19}\,\mathrm{C})}=\boxed{1.56\times10^{20}\ \mathrm{m}^{-3}}$$

Semiconductor Junctions and Devices

49 •• Simple theory for the current versus the bias voltage across a *pn* junction yields the equation $I = I_0\left(e^{eV_b/kT} - 1\right)$. Sketch I versus V_b for both positive and negative values of V_b using this equation.

Picture the Problem The following graph of I/I_0 versus V_b was plotted using a spreadsheet program.



50 • The base current in an *npn* transistor circuit is 25.0 mA. If 88.0 percent of the electrons entering the base from the emitter reach the collector, what is the base current?

Picture the Problem The base current is the difference between the emitter current and the plate current.

The base current I_B is given by: $$I_B = I - I_C$$

We're given that: $$I_C = 0.880I = 25.0\,\text{mA}$$

Solving for I gives: $$I = \frac{25.0\text{ mA}}{0.880} = 28.4\,\text{mA}$$

Substitute numerical values for I and I_C and evaluate I_B: $$I_B = 28.4\,\text{mA} - 25.0\,\text{mA} = \boxed{3.4\,\text{mA}}$$

51 •• [SSM] In Figure 38-28 for the *pnp*-transistor amplifier, suppose $R_b = 2.00\ \text{k}\Omega$ and $R_L = 10.0\ \text{k}\Omega$. Suppose further that a 10.0-μA ac base current i_b generates a 0.500-mA ac collector current i_c. What is the voltage gain of the amplifier?

Picture the Problem We can use its definition to compute the voltage gain of the amplifier.

The voltage gain of the amplifier is given by:

$$\text{Voltage gain} = \frac{i_c R_L}{i_b R_b}$$

Substitute numerical values and evaluate the voltage gain:

$$\text{Voltage gain} = \frac{(0.500\,\text{mA})(10.0\,\text{k}\Omega)}{(10.0\,\mu\text{A})(2.00\,\text{k}\Omega)} = \boxed{250}$$

52 •• Germanium can be used to measure the energy of incident photons. Consider a 660-keV gamma ray emitted from ^{137}Cs. (*a*) Given that the band gap in germanium is 0.72 eV, how many electron–hole pairs can be generated as this gamma ray travels through germanium? (*b*) The number *N* of pairs in Part (*a*) will have statistical fluctuations given by $\pm\sqrt{N}$. What then is the energy resolution of this detector in this photon energy region?

Picture the Problem The number of electron-hole pairs *N* is related to the energy *E* of the incident beam and the energy gap E_g.

(*a*) The number of electron-hole pairs *N* is given by:

$$N = \frac{E}{E_g}$$

Substitute numerical values and evaluate *N*:

$$N = \frac{660\,\text{keV}}{0.72\,\text{eV}} = 9.17\times10^5 = \boxed{9.2\times10^5}$$

(*b*) The energy resolution of the detector is given by:

$$\frac{\Delta E}{E} = \frac{\Delta N}{N}$$

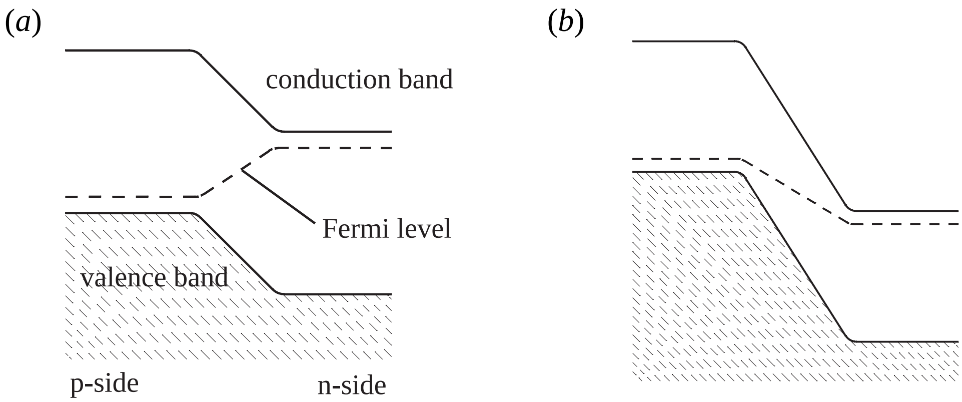
For $\Delta N = 1$ and $N = \sqrt{9.17\times10^5}$:

$$\frac{\Delta E}{E} = \frac{1}{\sqrt{9.17\times10^5}} = \boxed{0.10\%}$$

53 •• Make a sketch showing the valence and conduction band edges and Fermi energy of a *pn*-junction diode when biased (*a*) in the forward direction and (*b*) in the reverse direction.

Picture the Problem The nearly full valence band is shown shaded in the

diagram to the right. The Fermi level is shown by the dashed line.



54 •• A good silicon diode has the current–voltage characteristic given by $I = I_0\left(e^{eV_b/kT} - 1\right)$. Let kT = 0.025 eV (room temperature) and the saturation current I_0 = 1.0 nA. (*a*) Show that for small reverse-bias voltages, the resistance is 25 MΩ. *Hint: Do a Taylor-series expansion of the exponential function about* V_b = 0, *or use the expansion for* e^x *found in Table M-4 of the Math Tutorial.* (*b*) Find the dc resistance for a reverse bias of 0.50 V. (*c*) Find the resistance V/I for a 0.50-V forward bias. What is the current in this case? (*d*) Calculate the ac resistance dV/dI for a 0.50-V forward bias.

Picture the Problem We can use Ohm's law and the expression for the current given in the problem statement to find the resistance for small reverse-and-forward bias voltages.

(*a*) Use Ohm's law to express the resistance:

$$R = \frac{V_b}{I} \quad (1)$$

We're given that:

$$I = I_0\left(e^{eV_b/kT} - 1\right) \quad (2)$$

For $eV_b << kT$:

$$e^{eV_b/kT} - 1 \approx 1 + \frac{eV_b}{kT} - 1 = \frac{eV_b}{kT}$$

Substitute for $e^{eV_b/kT} - 1$ to obtain:

$$I = I_0\frac{eV_b}{kT}$$

Substitute for I in equation (1) and simplify:

$$R = \frac{V_b}{I_0\dfrac{eV_b}{kT}} = \frac{kT}{eI_0}$$

Substitute numerical values and evaluate R:

$$R = \frac{(0.025\,\mathrm{eV})(1.602\times10^{-19}\ \mathrm{J/eV})}{(1.602\times10^{-19}\ \mathrm{C})(1.0\,\mathrm{nA})} = \boxed{25\,\mathrm{M}\Omega}$$

(b) Substitute equation (2) in equation (1) to obtain:

$$R = \frac{V_\mathrm{b}}{I_0\left(e^{eV_\mathrm{b}/kT}-1\right)} \qquad (3)$$

Evaluate $\frac{eV_\mathrm{b}}{kT}$ for $V_\mathrm{b} = -\,0.50$ V:

$$\frac{eV_\mathrm{b}}{kT} = \frac{(1.602\times10^{-19}\ \mathrm{C})(-\,0.50\,\mathrm{V})}{(0.025\,\mathrm{eV})(1.602\times10^{-19}\ \mathrm{J/eV})} = -19.8$$

Evaluate equation (3) for $V_\mathrm{b} = -\,0.50$ V:

$$R = \frac{-\,0.50\,\mathrm{V}}{(1.0\,\mathrm{nA})\left(e^{-19.8}-1\right)} = \boxed{5.0\times10^{8}\ \Omega}$$

(c) The resistance V/I is given by:

$$R = \frac{V}{I} = \frac{V}{I_0\left(e^{eV_\mathrm{b}/kT}-1\right)} \qquad (4)$$

Evaluate $\frac{eV_\mathrm{b}}{kT}$ for $V_\mathrm{b} = +\,0.50$ V:

$$\frac{eV_\mathrm{b}}{kT} = \frac{(1.602\times10^{-19}\ \mathrm{C})(0.50\,\mathrm{V})}{(1.381\times10^{-23}\ \mathrm{J/K})(293\,\mathrm{K})} = 19.8$$

Substituting numerical values in equation (4) gives:

$$R = \frac{0.50\,\mathrm{V}}{(1.0\,\mathrm{nA})\left(e^{19.8}-1\right)} = \boxed{1.3\Omega}$$

From equation (1):

$$I = \frac{0.50\,\mathrm{V}}{1.3\Omega} = \boxed{0.38\,\mathrm{A}}$$

(d) Evaluate $R_\mathrm{ac} = dV/dI$ to obtain:

$$R_\mathrm{ac} = \frac{dV}{dI} = \left(\frac{dI}{dV}\right)^{-1} = \left\{\frac{d}{dV}\left[I_0\left(e^{eV_\mathrm{b}/kT}-1\right)\right]\right\}^{-1} = \left\{\frac{eI_0}{kT}e^{eV_\mathrm{b}/kT}\right\}^{-1} = \frac{kT}{eI_0}e^{-eV_\mathrm{b}/kT}$$

Substitute numerical values and evaluate R_ac:

$$R_\mathrm{ac} = (25\,\mathrm{M}\Omega)e^{-19.8} = \boxed{63\,\mathrm{m}\Omega}$$

55 •• A differential long slab of silicon of thickness t = 1.0 mm and width w = 1.0 cm is placed in a magnetic field B = 0.40 T. The slab is in the xy plane with the length of the slab parallel with the x axis, and the magnetic field points in the +z direction. When a current of 0.20 A exists in the sample in the +x direction, a potential difference of 5.0 mV develops across the width of the sample and the electric field in the sample points in the +y direction. Determine the semiconductor type (n or p) and the concentration of charge carriers. (The Hall effect is presented in Chapter 26.)

Picture the Problem We can use the Hall-effect equation to find the concentration of charge carriers in the slab of silicon. We can determine the semiconductor type by determining the directions of the magnetic and electric fields.

Use the expression for the Hall-effect voltage to relate the concentration of charge carriers n to the Hall voltage V_H:

$$V_H = \frac{IB}{nte} \Rightarrow n = \frac{IB}{teV_H}$$

Substitute numerical values and evaluate n:

$$n = \frac{(0.20\,\text{A})(0.40\,\text{T})}{(1.0\,\text{mm})(1.602\times10^{-19}\,\text{C})(5.0\,\text{mV})} = \boxed{1.0\times10^{23}\,\text{m}^{-3}}$$

Referring to Figure 26-28, note that $\vec{B}$ points out of the page. $\vec{E}$ is in the +y direction. Therefore, the charge carriers are holes and the semiconductor is p-type.

The BCS Theory

56 • (a) Use Equation 38-37 to calculate the superconducting energy gap for tin, and compare your result with the measured value of 6.00×10^{-4} eV. (b) Use the measured value to calculate the minimum value of the wavelength of a photon that has sufficient energy to break up Cooper pairs in tin (T_c = 3.72 K) at T = 0.

Picture the Problem We can calculate E_g using $E_g = 3.5kT_c$ and find the minimum value of the wavelength of a photon that has sufficient energy to break up Cooper pairs in tin at T = 0 using $\lambda = hc/E_g$.

(a) From Equation 38-37 we have:

$$E_g = 3.5kT_c$$

Substitute numerical values and evaluate E_g:

$$E_g = 3.5(8.617\times10^{-5}\,\text{eV/K})(3.72\,\text{K}) = \boxed{1.12\,\text{meV}}$$

Express the ratio of E_g to $E_{g,measured}$:

$$\frac{E_g}{E_{g,measured}} = \frac{1.12\,meV}{6.0\times10^{-4}\,eV} = 1.87$$

or

$$E_g \approx \boxed{2E_{g,measured}}$$

(*b*) The minimum value of the wavelength of a photon that has sufficient energy to break up Cooper pairs in tin at $T = 0$ is given by:

$$\lambda = \frac{hc}{E_g}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,eV\cdot nm}{6.00\times10^{-4}\,eV} = \boxed{2.07\,mm}$$

57 • **[SSM]** (*a*) Use Equation 38-37 to calculate the superconducting energy gap for lead, and compare your result with the measured value of 2.73×10^{-3} eV. (*b*) Use the measured value to calculate the minimum value of the wavelength of a photon that has sufficient energy to break up Cooper pairs in lead (T_c = 7.19 K) at $T = 0$.

Picture the Problem We can calculate E_g using $E_g = 3.5kT_c$ and find the minimum value of the wavelength of a photon that has sufficient energy to break up Cooper pairs in lead at $T = 0$ using $\lambda = hc/E_g$.

(*a*) From Equation 38-37 we have:

$$E_g = 3.5kT_c$$

Substitute numerical values and evaluate E_g:

$$E_g = 3.5\left(8.62\times10^{-5}\,eV/K\right)\left(7.19\,K\right) = \boxed{2.17\,meV}$$

Express the ratio of E_g to $E_{g,measured}$:

$$\frac{E_g}{E_{g,measured}} = \frac{2.17\,meV}{2.73\times10^{-3}\,eV} = 0.795$$

or

$$E_g \approx \boxed{0.8E_{g,measured}}$$

(*b*) The minimum value of the wavelength of a photon that has sufficient energy to break up Cooper pairs in lead at $T = 0$ is given by:

$$\lambda = \frac{hc}{E_g}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,\text{eV}\cdot\text{nm}}{2.73\times10^{-3}\,\text{eV}} = \boxed{0.454\,\text{mm}}$$

The Fermi-Dirac Distribution

58 •• The number of electrons in the conduction band of an insulator or intrinsic semiconductor is governed chiefly by the Fermi factor. Because the valence band in these materials is nearly filled and the conduction band is nearly empty, the Fermi energy E_F is generally midway between the top of the valence band and the bottom of the conduction band; that is, it is at $E_g/2$, where E_g is the band gap between the two bands and the energy is measured from the top of the valence band. (*a*) In silicon, $E_g \approx 1.0$ eV. Show that in this case the Fermi factor for electrons at the bottom of the conduction band is given by $\exp(-E_g/2kT)$ and evaluate this factor. Discuss the significance of this result if there are 10^{22} valence electrons per cubic centimeter and the probability of finding an electron in the conduction band is given by the Fermi factor. (*b*) Repeat the calculation in Part (*a*) for an insulator with a band gap of 6.0 eV.

Picture the Problem We can evaluate the Fermi factor at the bottom of the conduction band for T near room temperature to show that this factor is given by $\exp(-E_g/2kT)$.

(*a*) At the bottom of the conduction band:

$e^{(E-E_F)/kT} = e^{E_g/2kT} >>> 1$ for T near room temperature.

Neglecting the 1 in the denominator of the Fermi function yields:

$$f\left(\tfrac{1}{2}E_g\right) = \frac{1}{e^{E_g/2kT}} = \boxed{e^{-E_g/2kT}}$$

Substitute numerical values and evaluate $f\left(\tfrac{1}{2}E_g\right)$ for $T = 300$ K:

$$f\left(\tfrac{1}{2}E_g\right) = \exp\left[\frac{-1.0\,\text{eV}}{2\left(8.62\times10^{-5}\,\text{eV/K}\right)\left(300\,\text{K}\right)}\right] = \boxed{4.0\times10^{-9}}$$

Given that low a probability of finding an electron in a state near the bottom of the conduction band, the exclusion principle has no significant impact on the distribution function. With 10^{22} valence electrons per cm^3, the number of electrons in the conduction band will be about 4×10^{13} per cm^3.

(*b*) Evaluate $f\left(\frac{1}{2}E_g\right)$ for $T = 300$ K and $E_g = 6$ eV:

$$f\left(\tfrac{1}{2}E_g\right) = \exp\left[\frac{-6.0\,\text{eV}}{2\left(8.62\times10^{-5}\ \text{eV/K}\right)\left(300\,\text{K}\right)}\right] = \boxed{4.2\times10^{-51}}$$

The probability of finding even one electron in the conduction band is negligibly small (approximately 4×10^{-51}).

59 •• Approximately how many energy states that have energies between 2.00 eV and 2.20 eV are available to electrons in a cube of silver measuring 1.00 mm on a side?

Picture the Problem The number of energy states per unit volume per unit energy interval N is given by $N \approx g(E)\Delta E$, where N is only approximate, because ΔE is not infinitesimal and $g(E) = \frac{8\sqrt{2}\pi m_e^{3/2}V}{h^3}E^{1/2}$ is the density of states.

The number of states N is the product of the density of states and the energy interval:

$$N \approx g(E)\Delta E \qquad (1)$$

The density of states is given by:

$$g(E) = \frac{8\sqrt{2}\pi m_e^{3/2}V}{h^3}E^{1/2}$$

Substitute numerical values and evaluate $g(E)$:

$$g(E) = \frac{8\sqrt{2}\pi\left(9.109\times10^{-31}\ \text{kg}\right)^{3/2}\left(1.00\times10^{-3}\ \text{m}\right)^3}{\left(6.626\times10^{-34}\ \text{J}\cdot\text{s}\right)^3}\left(2.10\,\text{eV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)^{1/2}$$
$$= 6.15\times10^{37}\ \text{J}^{-1}$$

Substitute numerical values in equation (1) and evaluate N:

$$N \approx \left(6.15\times10^{37}\ \text{J}^{-1}\right)\left(2.20\,\text{eV} - 2.00\,\text{eV}\right)\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}} \approx \boxed{2.0\times10^{18}}$$

60 •• Show that at $E = E_F$, the expression for the Fermi factor (Equation 38-24) is equal to 0.5.

Picture the Problem Evaluating $f(E_F)$ at $E = E_F$ will show that $f(E) = 0.5$.

The Fermi factor is:

$$f(E) = \frac{1}{e^{(E-E_F)/kT} + 1}$$

Evaluate $f(E_F)$:

$$f(E_F) = \frac{1}{e^{(E_F-E_F)/kT} + 1} = \frac{1}{1+1} = \boxed{0.5}$$

61 •• **[SSM]** (*a*) Using the equation $E_F = \left[h^2/(8m_e)\right]\left[3N/(\pi V)\right]^{2/3}$ (Equation 38-22*a*), calculate the Fermi energy for silver. (*b*) Determine the average kinetic energy of a free electron and (*c*) find the Fermi speed for silver.

Picture the Problem Equation 38-22*a* expresses the dependence of the Fermi energy E_F on the number density of free electrons. Once we've determined the Fermi energy for silver, we can find the average kinetic energy of a free electron from the Fermi energy for silver and then use the average kinetic energy of a free electron to find the Fermi speed for silver.

(*a*) From Equation 38-22*a* we have:

$$E_F = \frac{h^2}{8m_e}\left(\frac{3N}{\pi V}\right)^{2/3}$$

Use Table 27-1 to find the free-electron number density N/V for silver:

$$\frac{N}{V} = 5.86\text{x}10^{22}\ \frac{\text{electrons}}{\text{cm}^3} = 5.86\text{x}10^{28}\ \frac{\text{electrons}}{\text{m}^3}$$

Substitute numerical values and evaluate E_F:

$$E_F = \frac{\left(6.626\times10^{-34}\,\text{J}\cdot\text{s}\right)^2}{8\left(9.109\times10^{-31}\,\text{kg}\right)}\left[\frac{3\left(5.86\times10^{28}\,\text{electrons/m}^3\right)}{\pi}\right]^{2/3}\left(\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}\right) = \boxed{5.51\,\text{eV}}$$

(*b*) The average kinetic energy of a free electron is given by:

$$E_{av} = \frac{3}{5}E_F$$

Substitute numerical values and evaluate E_{av}:

$$E_{av} = \frac{3}{5}(5.51\,\text{eV}) = \boxed{3.31\,\text{eV}}$$

(*c*) Express the Fermi energy in terms of the Fermi speed of the electrons:

$$E_F = \tfrac{1}{2}m_e u_F^2 \Rightarrow u_F = \sqrt{\frac{2E_F}{m_e}}$$

Substitute numerical values and evaluate u_F:

$$u_F = \sqrt{\frac{2(3.31\,\text{eV})}{9.109\times10^{-31}\,\text{kg}}\left(\frac{1.602\times10^{-19}\,\text{J}}{1\,\text{eV}}\right)} = \boxed{1.08\times10^{6}\ \text{m/s}}$$

62 •• What is the difference between the energies at which the Fermi factor is 0.9 and 0.1 at 300 K in (*a*) copper, (*b*) potassium, and (*c*) aluminum.

Picture the Problem We can find the difference between the energies at which the Fermi factor has the given values by solving the expression for Fermi factor for *E* and then deriving an expression for Δ*E*.

(*a*) The Fermi factor is:

$$f(E) = \frac{1}{e^{(E-E_F)/kT}+1}$$

Solving for *E* gives:

$$E = E_F + kT\ln\left(\frac{1}{f(E)}-1\right)$$

The difference between the energies is given by:

$$\begin{aligned}
\Delta E &= E(0.1) - E(0.9) \\
&= E_F + \frac{(1.381\times10^{-23}\ \text{J/K})(300\,\text{K})}{1.602\times10^{-19}\ \text{J/eV}}\ln\left(\frac{1}{0.1}-1\right) \\
&\quad - \left\{E_F + \frac{(1.381\times10^{-23}\ \text{J/K})(300\,\text{K})}{1.602\times10^{-19}\ \text{J/eV}}\ln\left(\frac{1}{0.9}-1\right)\right\} \\
&= \frac{(1.381\times10^{-23}\ \text{J/K})(300\,\text{K})}{1.602\times10^{-19}\ \text{J/eV}}\left[\ln\left(\frac{1}{0.1}-1\right) - \ln\left(\frac{1}{0.9}-1\right)\right] \\
&= \boxed{0.114\,\text{eV}}
\end{aligned}$$

(*b*) and (*c*) Because Δ*E* is independent of E_F, Δ*E* is the same as in (*a*).

63 •• **[SSM]** What is the probability that a conduction electron in silver will have a kinetic energy of 4.90 eV at *T* = 300 K?

Picture the Problem The probability that a conduction electron will have a given kinetic energy is given by the Fermi factor.

The Fermi factor is:

$$f(E)=\frac{1}{e^{(E-E_\mathrm{F})/kT}+1}$$

Because E_F – 4.90 eV >> 300k:

$$f(4.90\,\mathrm{eV})=\frac{1}{0+1}=\boxed{1}$$

64 •• Show that $g(E)=\frac{3}{2}NE_\mathrm{F}^{-3/2}E^{1/2}$ (Equation 38-43) follows from Equation 38-41 for $g(E)$, and from Equation 38-22a for E_F.

Picture the Problem We can solve Equation 38-22a for V and substitute in Equation 38-41 to show that $g(E)=\frac{3}{2}NE_\mathrm{F}^{-3/2}E^{1/2}$.

From Equation 38-22a we have:

$$E_\mathrm{F}=\frac{h^2}{8m_\mathrm{e}}\left(\frac{3N}{\pi V}\right)^{2/3}$$

Solving for V yields:

$$V=\frac{3N}{\pi}\left(\frac{h^2}{8m_\mathrm{e}E_\mathrm{F}}\right)^{3/2}$$

The density $g(E)$ is given by Equation 38-41:

$$g(E)=\frac{8\pi\sqrt{2}m_\mathrm{e}^{3/2}V}{h^3}E^{1/2}$$

Substitute for V and simplify to obtain:

$$g(E)=\frac{8\pi\sqrt{2}m_\mathrm{e}^{3/2}}{h^3}\left[\frac{3N}{\pi}\left(\frac{h^2}{8m_\mathrm{e}E_\mathrm{F}}\right)^{3/2}\right]E^{1/2}$$
$$=\boxed{\frac{3}{2}NE_\mathrm{F}^{-3/2}E^{1/2}}$$

65 •• Carry out the integration $E_\mathrm{av}=(1/N)\int_0^{E_\mathrm{F}}Eg(E)dE$ to show that the average energy at T = 0 is $\frac{3}{5}E_\mathrm{F}$.

Picture the Problem We can use the expression for $g(E)$ from Problem 64 to show that the average energy at T = 0 is $\frac{3}{5}E_\mathrm{F}$.

From Problem 64 we have:

$$g(E)=\frac{3}{2}NE_\mathrm{F}^{-3/2}E^{1/2}$$

Substitute in the expression for E_{av} and simplify to obtain:

$$E_{av}=\frac{1}{N}\int_0^{E_F}Eg(E)dE$$
$$=\frac{1}{N}\int_0^{E_F}E\left(\frac{3N}{2}E_F^{-3/2}E^{1/2}\right)dE$$
$$=\frac{3}{2}E_F^{-3/2}\int_0^{E_F}E^{3/2}dE$$

Integrating the expression for E_{av} gives:

$$E_{av}=\frac{3}{2}E_F^{-3/2}\int_0^{E_F}E^{3/2}dE$$
$$=\left(\tfrac{3}{2}E_F^{-3/2}\right)\left(\tfrac{2}{5}E_F^{5/2}\right)$$
$$=\boxed{\tfrac{3}{5}E_F}$$

66 •• The density of the electron states in a metal can be written $g(E) = AE^{1/2}$, where A is a constant and E is measured from the bottom of the conduction band. (*a*) Show that the total number of states is $\tfrac{2}{3}AE_F^{3/2}$. (*b*) Approximately what fraction of the conduction electrons are within kT of the Fermi energy? (*c*) Evaluate this fraction for copper at T = 300 K.

Picture the Problem We can integrate $g(E)$ from 0 to E_F to show that the total number of states is $\tfrac{2}{3}AE_F^{3/2}$.

(*a*) Integrate $g(E)$ from 0 to E_F:

$$N=\int_0^{E_F}AE^{1/2}dE=\boxed{\tfrac{2}{3}AE_F^{3/2}}$$

(*b*) Express the fraction of N within kT of E_F:

$$\frac{kTg(E_F)}{N}=\frac{kTAE_F^{1/2}}{\tfrac{2}{3}AE_F^{3/2}}=\boxed{\frac{3kT}{2E_F}}$$

(*c*) Substitute numerical values and evaluate the expression obtained in (*b*) for copper:

$$\frac{3kT}{2E_F}=\frac{3\left(8.62\times10^{-5}\ \text{eV/K}\right)\left(300\ \text{K}\right)}{2\left(7.04\ \text{eV}\right)}$$
$$=\boxed{5.51\times10^{-3}}$$

67 •• What is the probability that a conduction electron in silver will have a kinetic energy of 5.49 eV at T = 300 K?

Picture the Problem The probability that a conduction electron in metal is the Fermi factor.

The Fermi factor is:

$$f(E)=\frac{1}{e^{(E-E_\mathrm{F})/kT}+1}$$

Calculate the dimensionless exponent in the Fermi factor:

$$\frac{E-E_\mathrm{F}}{kT}=\frac{5.49\,\mathrm{eV}-5.50\,\mathrm{eV}}{(8.617\times10^{-5}\ \mathrm{eV/K})(300\,\mathrm{K})}$$
$$=-0.387$$

Use this result to calculate the Fermi factor:

$$f(5.49\,\mathrm{eV})=\frac{1}{e^{-0.387}+1}=\boxed{0.60}$$

68 •• Using the expression $g(E)=\left(8\sqrt{2}\pi m_\mathrm{e}^{3/2}V/h^3\right)E^{1/2}$ (Equation38-41) for the density of states, estimate the fraction of the conduction electrons in copper that can absorb energy from collisions with the vibrating lattice ions at (*a*) 77 K and (*b*) 300 K.

Picture the Problem We can integrate the density-of-states function, Equation 38-41, to find the number of occupied states *N*. The fraction of these states that are within *kT* of E_F can then be found from the ratio of $kTg(E_\mathrm{F})$ to *N*.

The density of states function is:

$$g(E)=AE^{1/2}\text{ where }A=\frac{8\pi\sqrt{2}m_\mathrm{e}^{3/2}V}{h^3}$$

Integrate $g(E)$ from 0 to E_F to find the total number of occupied states:

$$N=\int_0^{E_\mathrm{F}}AE^{1/2}dE=\tfrac{2}{3}AE_{E_\mathrm{F}}^{3/2}$$

Express the fraction of *N* within *kT* of E_F:

$$\frac{kTg(E_\mathrm{F})}{N}=\frac{kTAE_\mathrm{F}^{1/2}}{\frac{2}{3}AE_\mathrm{F}^{3/2}}=\frac{3kT}{2E_\mathrm{F}}$$

(*a*) Substitute numerical values and evaluate the expression obtained above for copper at T = 77 K:

$$\frac{3kT}{2E_\mathrm{F}}=\frac{3(8.617\times10^{-5}\ \mathrm{eV/K})(77\,\mathrm{K})}{2(7.04\,\mathrm{eV})}$$
$$=\boxed{1.4\times10^{-3}}$$

(*b*) At T = 300 K:

$$\frac{3kT}{2E_\mathrm{F}}=\frac{3(8.617\times10^{-5}\ \mathrm{eV/K})(300\,\mathrm{K})}{2(7.04\,\mathrm{eV})}$$
$$=\boxed{5.51\times10^{-3}}$$

69 •• In an intrinsic semiconductor, the Fermi energy is about midway between the top of the valence band and the bottom of the conduction band. In germanium, the forbidden energy band has a width of 0.70 eV. Show that at room

temperature the distribution function of electrons in the conduction band is given by the Maxwell–Boltzmann distribution function.

Picture the Problem The distribution function of electrons in the conduction band is given by $n(E)=g(E)f(E)$ where $f(E)$ is the Fermi factor and $g(E)$ is the density of states in terms of E_F.

Express the number of electrons n with energy E:

$$n(E)=g(E)f(E) \qquad (1)$$

where

$$g(E)=\frac{3N}{2}E_{E_F}^{-3/2}E^{1/2}$$

and

$$f(E)=\frac{1}{e^{(E-E_F)/kT}+1}$$

The dimensionless exponent in the Fermi factor is:

$$\frac{E-E_F}{kT}=\frac{E-\frac{1}{2}E_g}{kT}>>1$$

and

$$\exp\left(\frac{E-\frac{1}{2}E_g}{kT}\right)>>1$$

Hence:

$$f(E)=\frac{1}{e^{\left(E-\frac{1}{2}E_g\right)/kT}}\approx e^{E_g/2kT}e^{-E/kT}$$

Substitute in equation (1) and simplify to obtain:

$$n(E)=\boxed{\left(\tfrac{3}{2}NE_F^{-3/2}e^{E_g/2kT}\right)E^{1/2}e^{-E/kT}}$$

There is an additional temperature dependence that arises from the fact that E_F depends on T. At room temperature,

$$\exp[(E-E_g/2)/kT]\geq\exp(0.35\text{ eV}/0.0259\text{ eV})=7.4\times10^5,$$

so the approximation leading to the Boltzmann distribution is justified.

70 ••• The root-mean-square (rms) value of a variable is obtained by calculating the average value of the square of that variable and then taking the square root of the result. Use this procedure to determine the rms energy of a Fermi distribution. Express your result in terms of E_F and compare it to the average energy. Why do E_{av} and E_{rms} differ?

Picture the Problem We can follow the procedure outlined in the problem statement to determine the rms energy of a Fermi distribution.

Express the E_{rms} in terms of $g(E)$:

$$E_{rms} = \left(\frac{1}{N}\int_0^{E_F} g(E)E^2 dE\right)^{1/2}$$

The density of states $g(E)$ is given by:

$$g(E) = \frac{3N}{2}E_F^{-3/2}E^{1/2}$$

Substitute to obtain:

$$E_{rms} = \left(\frac{1}{2NE_F^{3/2}}\int_0^{E_F} E^{3/2} dE\right)^{1/2}$$

Evaluate the integral and simplify to obtain:

$$E_{rms} = \sqrt{\frac{3}{7}}E_F = \boxed{0.655E_F}$$

$E_{rms} > E_{av}$ because the process of averaging the square of the energy weights larger energies more heavily.

General Problems

71 • The density of potassium is 0.851 g/cm^3. How many free electrons are there per potassium atom in a crystal of potassium?

Picture the Problem The number of free electrons per atom n_e is given by $n_e = nM/\rho N_A$ where N_A is Avogadro's number, ρ is the density of the element, M is its molar mass, and n is the free electron number density for the element.

The number of electrons per atom is given by:

$$n_e = \frac{nM}{\rho N_A}$$

From Table 38-1:

$$n = 14.0\ \text{electrons/nm}^3$$
$$= 1.40\times10^{22}\ \text{electrons/cm}^3$$

Substitute numerical values and evaluate n_e:

$$n_e = \frac{(1.40\times10^{22}\ \text{electrons/cm}^3)(39.098\,\text{g}/\text{mol})}{(0.851\text{g/cm}^3)(6.022\times10^{23}\ \text{electrons/mol})} = \boxed{1.07}$$

Remarks: Our result of 1.07 free electrons per potassium atom means that, for every 100 potassium atoms, there are 107 free electrons.

72 • Calculate the number density of free electrons for (*a*) magnesium, which has a density of 1.74 g/cm^3, and (*b*) zinc, which has a density of 7.14 g/cm^3. For these calculations assume there are two free electrons per atom, and compare your results with the values listed in Table 38-1.

Picture the Problem The number of free electrons per atom n_e is related to the number density of free electrons n by $n_e = nM/\rho N_A$, where N_A is Avogadro's number, ρ is the density of the element, and M is its molar mass.

The number of electrons per atom is given by:

$$n_e = \frac{nM}{\rho N_A}$$

Solving for n gives:

$$n = \frac{n_e \rho N_A}{M}$$

(*a*) Substitute numerical values and evaluate n for Mg:

$$n_{Mg} = \frac{(2)(1.74\,\mathrm{g/cm^3})(6.022\times10^{23}\,\mathrm{electrons/mol})}{24.31\,\mathrm{g/mol}} = \boxed{8.62\times10^{22}\,\mathrm{electrons/cm^3}}$$

(*b*) Substitute numerical values and evaluate n for Zn:

$$n_{Zn} = \frac{(2)(7.14\,\mathrm{g/cm^3})(6.022\times10^{23}\,\mathrm{electrons/mol})}{65.38\,\mathrm{g/mol}} = \boxed{1.32\times10^{23}\,\mathrm{electrons/cm^3}}$$

Both results agree with the values in Table 38-1 to within 1%.

73 •• Estimate the fraction of free electrons in copper that are in energy states above the Fermi energy at (*a*) 300 K (about room temperature) and (*b*) at 1000 K.

Picture the Problem We can integrate $g(E)$ from 0 to E_F to show that the total number of states is $\frac{2}{3}AE_F^{3/2}$ and then use this result to find the fraction of the free electrons that are above the Fermi energy at the given temperatures.

Integrate $g(E)$ from 0 to E_F:

$$N = \int_0^{E_F} AE^{1/2}dE = \frac{2}{3}AE_{E_F}^{3/2}$$

Express the fraction of N within kT of E_F:

$$\frac{kTg(E_F)}{N}=\frac{kTAE_F^{1/2}}{\frac{2}{3}AE_F^{3/2}}=\frac{3kT}{2E_F}$$

(*a*) Substitute numerical values and evaluate this fraction for copper at 300 K:

$$\frac{3kT}{2E_F}=\frac{3(8.617\times10^{-5}\text{ eV/K})(300\text{ K})}{2(7.04\text{ eV})}=\boxed{5.51\times10^{-3}}$$

(*b*) Evaluate the same fraction at 1000 K:

$$\frac{3kT}{2E_F}=\frac{3(8.617\times10^{-5}\text{ eV/K})(1000\text{ K})}{2(7.04\text{ eV})}=\boxed{1.84\times10^{-2}}$$

74 •• A certain free-electron energy state of manganese has a 10.0 percent chance of being occupied when the temperature of the manganese is T = 1300 K. What is the energy of this state?

Picture the Problem The Fermi factor gives the probability of an energy state being occupied as a function of the energy of the state E, the Fermi energy E_F for the particular material, and the temperature T.

The Fermi factor is:

$$f(E)=\frac{1}{e^{(E-E_F)/kT}+1}$$

For 10 percent probability:

$$0.1=\frac{1}{e^{(E-E_F)/kT}+1}\Rightarrow e^{(E-E_F)/kT}=9$$

Take the natural logarithm of both sides of $e^{(E-E_F)/kT}=9$ to obtain:

$$\frac{E-E_F}{kT}=\ln(9)\Rightarrow E=E_F+kT\ln(9)$$

From Table 37-1, $E_{F,\,Mn}$ = 11.0 eV. Substitute numerical values and evaluate E:

$$E=11.0\text{ eV}+(1.381\times10^{-23}\text{ J/K})(1300\text{ K})\left(\frac{1\text{ eV}}{1.602\times10^{-19}\text{ J}}\right)\ln 9=\boxed{11.2\text{ eV}}$$

75 •• The semiconducting compound CdSe is widely used for light-emitting diodes (LEDs). The energy gap in CdSe is 1.80 eV. What is the frequency of the light emitted by a CdSe LED?

Picture the Problem The energy gap for the semiconductor is related to the wavelength of the emitted light according to $E_g=hc/\lambda$.

The frequency of the emitted light is related to its wavelength:

$$f = \frac{c}{\lambda}$$

Express the energy gap E_g in terms of the wavelength λ of the emitted light:

$$E_g = \frac{hc}{\lambda} \Rightarrow \lambda = \frac{hc}{E_g}$$

Substituting for λ and simplifying yields:

$$f = \frac{c}{\frac{hc}{E_g}} = \frac{cE_g}{hc}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{(2.998\times10^8\ \text{m/s})(1.80\ \text{eV})}{1240\ \text{eV}\cdot\text{nm}} = \boxed{4.35\times10^{14}\ \text{Hz}}$$

Remarks: This frequency is in the red portion of the visible spectrum.

76 ••• A 2.00-cm^2 wafer of pure silicon is irradiated with electromagnetic radiation having a wavelength of 775 nm. The intensity of the radiation is 4.00 W/m^2 and every photon that strikes the sample is absorbed and creates an electron–hole pair. (*a*) How many electron–hole pairs are produced in one second? (*b*) If the number of electron–hole pairs in the sample is 6.25×10^{11} in the steady state, at what rate do the electron–hole pairs recombine? (*c*) If every recombination event results in the radiation of one photon, at what rate is energy radiated by the sample?

Picture the Problem The rate of production of electron-hole pairs is the ratio of the incident energy to the energy required to produce an electron-hole pair.

(*a*)The number of electron-hole pairs *N* produced in one second is:

$$N = \frac{IA}{\frac{hc}{\lambda}} = \frac{IA\lambda}{hc}$$

Substitute numerical values and evaluate *N*:

$$N = \frac{(4.00\,\text{W/m}^2)(2.00\times10^{-4}\ \text{m}^2)(775\,\text{nm})}{(1240\,\text{eV}\cdot\text{nm})(1.602\times10^{-19}\ \text{J/eV})} = \boxed{3.12\times10^{15}\ \text{s}^{-1}}$$

(*b*) In the steady state, the rate of recombination equals the rate of generation. Therefore:

$$N = \boxed{3.12\times10^{15}\ \text{s}^{-1}}$$

(*c*) The power radiated equals the power absorbed:

$$P_{\text{rad}} = IA$$

Substitute numerical values and evaluate P_{rad}:

$$P_{\text{rad}} = \left(4.00\,\text{W/m}^2\right)\left(2.00\times10^{-4}\,\text{m}^2\right) = \boxed{0.800\,\text{mJ/s}}$$

Chapter 39
Relativity

Conceptual Problems

1 • [SSM] The approximate total energy of a particle of mass m moving at speed $u << c$ is (a) $mc^2 + \frac{1}{2}mu^2$, (b) $\frac{1}{2}mu^2$, (c) cmu, (d) mc^2, (e) $\frac{1}{2}cmu$.

Determine the Concept The total relativistic energy E of a particle is defined to be the sum of its kinetic and rest energies.

The sum of the kinetic and rest energies of a particle is given by:

$$E = K + mc^2 = \tfrac{1}{2}mu^2 + mc^2$$

and $\boxed{(a)}$ is correct.

2 • A set of twins work in an office building. One twin works on the top floor and the other twin works in the basement. Considering general relativity, which twin will age more quickly? (a) They will age at the same rate. (b) The twin who works on the top floor will age more quickly. (c) The twin who works in the basement will age more quickly. (d) It depends on the speed of the office building. (e) None of the above.

Determine the Concept The gravitational field of Earth is slightly greater in the basement of the office building than it is at the top floor. Because clocks run more slowly in regions of low gravitational potential, clocks in the basement will run more slowly than clocks on the top floor. Hence, the twin who works on the top floor will age more quickly. $\boxed{(b)}$ is correct.

3 • True or false:

(a) The speed of light is the same in all reference frames.
(b) The time interval between two events is never shorter than the proper time interval between the two events.
(c) Absolute motion can be determined by means of length contraction.
(d) The light-year is a unit of distance.
(e) Simultaneous events must occur at the same place.
(f) If two events are not simultaneous in one frame, they cannot be simultaneous in any other frame.
(g) The mass of a system that consists of two particles that are tightly bound together by attractive forces is less than the sum of the masses of the individual particles when separated.

(a) True

(*b*) True

(*c*) False. The shortening of the length of an object in the direction in which it is moving is independent of the velocity of the frame of reference from which it is observed.

(*d*) True

(*e*) False. Consider two explosions equidistant, but in opposite directions, from an observer in the observer's frame of reference.

(*f*) False. Whether events appear to be simultaneous depends on the motion of the observer.

(*g*) True

4 • An observer sees a system moving past her that consists of a mass oscillating on the end of a spring and measures the period T of the oscillations. A second observer, who is moving with the mass–spring system, also measures its period. The second observer will find a period that is (*a*) equal to T, (*b*) less than T, (*c*) greater than T, (*d*) either (*a*) or (*b*) depending on whether the system was approaching or receding from the first observer, (*e*) Not enough information is given to answer the question.

Determine the Concept Because the clock is moving with respect to the first observer, a time interval will be longer for this observer than for the observer moving with the spring-and-mass oscillator. Hence, the observer moving with the system will measure a period that is less than T. $\boxed{(b)}$ is correct.

5 • The Lorentz transformation for y and z is the same as the classical result: $y = y'$ and $z = z'$. Yet the relativistic velocity transformation does not give the classical result $u_y = u'_y$ and $u_z = u'_z$. Explain why this result occurs.

Determine the Concept Although $\Delta y = \Delta y'$, $\Delta t \neq \Delta t'$. Consequently, $u_y = \Delta y/\Delta t' \neq \Delta y'/\Delta t' = u_y'$.

Estimation and Approximation

6 •• The Sun radiates energy at the rate of approximately 4×10^{26} W. Assume that this energy is produced by a reaction whose net result is the fusion of four protons to form a single ^{4}He nucleus and the release of 25 MeV of energy that is radiated into space. Calculate the Sun's loss of mass per day.

Picture the Problem We can calculate the Sun's loss of mass per day from the number of reactions per second and the loss of mass per reaction.

Express the rate at which the Sun loses mass:

$$\frac{\Delta M}{\Delta t} = N\Delta m \Rightarrow \Delta M = N\Delta m\Delta t$$

where N is the number of reactions per second and Δm is the loss of mass per reaction.

The number of reactions per second, N is given by:

$$N = \frac{P}{E/\text{reaction}}$$

Substitute for N to obtain:

$$\Delta M = \frac{P}{E/\text{reaction}}\Delta m\Delta t$$

The loss of mass per reaction Δm is:

$$\Delta m = \frac{E/\text{reaction}}{c^2}$$

Substituting for Δm and simplifying yields:

$$\Delta M = \left(\frac{P}{E/\text{reaction}}\right)\left(\frac{E/\text{reaction}}{c^2}\right)\Delta t = \frac{P}{c^2}\Delta t$$

Substitute numerical values and evaluate ΔM:

$$\Delta M = \frac{4\times10^{26}\ \text{W}}{\left(2.998\times10^{8}\ \text{m/s}\right)^2}\left(1\,\text{d}\times\frac{86.4\,\text{ks}}{\text{d}}\right) \approx \boxed{4\times10^{14}\ \text{kg}}$$

7 •• **[SSM]** The most distant galaxies that can be seen by the Hubble telescope are moving away from us and have a redshift parameter of about $z = 5$. (The redshift parameter z is defined as $(f - f')/f'$, where f is the frequency measured in the rest frame of the emitter, and f' is the frequency measured in the rest frame of the receiver.) (*a*) What is the speed of these galaxies relative to us (expressed as a fraction of the speed of light)? (*b*) *Hubble's law* states that the recession speed is given by the expression $v = Hx$, where v is the speed of recession, x is the distance, and H, the Hubble constant, is equal to 75 km/s/Mpc, where 1 pc = 3.26 c·y. (The abbreviation for parsec is pc.) Estimate the distance of such a galaxy from us using the information given.

Picture the Problem (*a*) We can use the definition of the redshift parameter and the relativistic Doppler shift equation to show that, for light that is Doppler-shifted with respect to an observer, $v = c\left(\frac{u^2 - 1}{u^2 + 1}\right)$, where $u = z + 1$, and to find the ratio of v to c. In Part (*b*) we can solve Hubble's law for x and substitute our result from Part (*a*) to estimate the distance to the galaxy.

(*a*) The red-shift parameter is defined to be:

$$z = \frac{f_0 - f'}{f'}$$

The relativistic Doppler shift for recession is given by:

$$f' = f_0\sqrt{\frac{1 - v/c}{1 + v/c}}$$

Substitute for f' and simplify to obtain:

$$z = \frac{f_0 - f_0\sqrt{\frac{1 - v/c}{1 + v/c}}}{f_0\sqrt{\frac{1 - v/c}{1 + v/c}}} = \sqrt{\frac{1 + v/c}{1 - v/c}} - 1$$

Letting $u = z + 1$ and simplifying yields:

$$u = z + 1 = \sqrt{\frac{1 + v/c}{1 - v/c}} \Rightarrow \frac{v}{c} = \frac{u^2 - 1}{u^2 + 1}$$

Substitute for u to express v/c as a function of z:

$$\frac{v}{c} = \frac{(z + 1)^2 - 1}{(z + 1)^2 + 1}$$

Substituting the numerical value of z and evaluating v/c gives:

$$\frac{v}{c} = \frac{(5 + 1)^2 - 1}{(5 + 1)^2 + 1} = \boxed{0.946}$$

(*b*) Solving Hubble's law for x yields:

$$x = \frac{v}{H}$$

Substitute numerical values and evaluate x:

$$x = \frac{0.946c}{H} = \frac{0.946c}{75\frac{\text{km/s}}{\text{Mpc}}} \times \frac{3.26 \times 10^6\ c \cdot \text{y}}{\text{Mpc}}$$

$$= \boxed{12.3\,\text{G}c \cdot \text{y}}$$

Time Dilation and Length Contraction

8 • The proper mean lifetime of a muon is 2.2 μs. Muons in a beam are traveling through a laboratory at 0.95*c*. (*a*) What is their mean lifetime as measured in the laboratory? (*b*) How far do they travel, on average, before they decay?

Picture the Problem We can find the mean lifetime of a muon as measured in the laboratory using $t' = \gamma t$ where $\gamma = 1\Big/\sqrt{1-(v/c)^2}$ and t is the proper mean lifetime of the muon. The distance L that the muon travels is the product of its speed and its mean lifetime in the laboratory.

(*a*) The mean lifetime of the muon, as measured in the laboratory, is given by:

$$t' = \frac{t}{\sqrt{1-\left(\frac{v}{c}\right)^2}}$$

Substitute numerical values and evaluate t':

$$t' = \frac{2.2\ \mu\text{s}}{\sqrt{1-\left(\frac{0.95c}{c}\right)^2}} = 7.046\ \mu\text{s} = \boxed{7.0\ \mu\text{s}}$$

(*b*) The distance L that the muon travels is related to its mean lifetime in the laboratory:

$$L = vt' = 0.95ct'$$

Substitute numerical values and evaluate L:

$$L = 0.95\left(2.998\times10^8\ \text{m/s}\right)\left(7.046\ \mu\text{s}\right) = \boxed{2.0\,\text{km}}$$

9 •• In the Stanford linear collider, small bundles of electrons and positrons are fired at each other. In the laboratory's frame of reference, each bundle is approximately 1.0 cm long and 10 μm in diameter. In the collision region, each particle has an energy of 50 GeV, and the electrons and the positrons are moving in opposite directions. (*a*) How long and how wide is each bundle in its own reference frame? (*b*) What must be the minimum proper length of the accelerator for a bundle to have both its ends simultaneously in the accelerator in its own reference frame? (The actual proper length of the accelerator is less than 1000 m.) (*c*) What is the length of a positron bundle in a reference frame that moves with the electron bundle?

Picture the Problem The proper length L_p of the beam is its length as measured in a reference frame in which it is not moving. The proper length is related to its length in the frame in which it is measured by $L_p = \gamma L$.

(*a*) Relate the proper length L_p of the beam to its length L in the laboratory frame of reference:

$$L_p = \gamma L$$

The energy of the beam also depends on γ:

$$E = \gamma mc^2$$

Solve for and evaluate γ:

$$\gamma = \frac{E}{mc^2} = \frac{50\,\text{GeV}}{0.511\,\text{MeV}} = 9.785\times10^4$$

Substitute numerical values and evaluate L_p:

$$L_p = \left(9.785\times10^4\right)(1.0\,\text{cm}) = 978.5\,\text{m} = \boxed{0.98\,\text{km}}$$

and the width w of the beam is unchanged.

(*b*) Express the length of the accelerator in the electron beam's frame of reference:

$$L_{\text{acc}} = \frac{L_{\text{acc,p}}}{\gamma}$$

Set $L_{\text{acc}} = L_p$:

$$L_p = \frac{L_{\text{acc,p}}}{\gamma} \Rightarrow L_{\text{acc,p}} = \gamma L_p$$

Substitute numerical values and evaluate $L_{\text{acc,p}}$:

$$L_{\text{acc,p}} = \left(9.785\times10^4\right)(978.5\,\text{m}) = \boxed{9.6\times10^7\ \text{m}}$$

(*c*) The length of the positron bundle in the electron's frame of reference is:

$$L_{\text{pos}} = \frac{L}{\gamma}$$

Substitute numerical values and evaluate L_{pos}:

$$L_{\text{pos}} = \frac{1.0\,\text{cm}}{9.785\times10^4} = \boxed{0.10\,\mu\text{m}}$$

10 • Use the binomial expansion equation

$$(1+x)^n = 1 + nx + \frac{n(n-1)}{2}x^2 + \cdots \approx 1 + nx, \qquad x << 1$$

to derive the following results for the case when v is much less than c, and use the results when applicable in the following problems:

(a) $\gamma \approx 1 + \frac{1}{2}\frac{v^2}{c^2}$

(b) $\frac{1}{\gamma} \approx 1 - \frac{1}{2}\frac{v^2}{c^2}$

(c) $\gamma - 1 \approx 1 - \frac{1}{\gamma} \approx \frac{1}{2}\frac{v^2}{c^2}$

Picture the Problem We can use the definition of γ and the binomial expansion of $(1 + x)^n$ to show that each of these relationships holds provided $v << c$.

(a) Express the gamma factor:

$$\gamma = \frac{1}{\sqrt{1-\frac{v^2}{c^2}}} = \left(1-\frac{v^2}{c^2}\right)^{-1/2}$$

Expand the radical factor binomially to obtain:

$$\gamma = \left(1-\frac{v^2}{c^2}\right)^{-1/2}$$

$$= 1 + \left(-\frac{1}{2}\right)\left(-\frac{v^2}{c^2}\right) + \text{higher order terms}$$

For $v << c$:

$$\gamma \approx \boxed{1 + \frac{1}{2}\frac{v^2}{c^2}}$$

(b) Express the reciprocal of γ:

$$\frac{1}{\gamma} = \sqrt{1-\frac{v^2}{c^2}}$$

Expand the radical binomially to obtain:

$$\frac{1}{\gamma} = \left(1-\frac{v^2}{c^2}\right)^{1/2}$$

$$= 1 + \left(\frac{1}{2}\right)\left(-\frac{v^2}{c^2}\right) + \text{higher order terms}$$

For $v << c$:

$$\frac{1}{\gamma} \approx \boxed{1 - \frac{1}{2}\frac{v^2}{c^2}}$$

(c) Express the gamma factor:

$$\gamma = \frac{1}{\sqrt{1-\frac{v^2}{c^2}}} = \left(1-\frac{v^2}{c^2}\right)^{-1/2}$$

Subtract one from both sides of the equation to obtain:

$$\gamma - 1 = \left(1-\frac{v^2}{c^2}\right)^{-1/2} - 1$$

Expand the radical binomially to obtain:

$$\gamma - 1 = 1 + \left(-\frac{1}{2}\right)\left(-\frac{v^2}{c^2}\right) - 1 + \text{higher order terms}$$

For $v << c$:

$$\gamma - 1 \approx \boxed{\frac{1}{2}\frac{v^2}{c^2}}$$

11 •• Star A and Star B are at rest relative to Earth. Star A is 27 c·y from Earth, and as viewed from Earth, Star B is located beyond (behind) Star A. (a) A spaceship is making a trip from Earth to Star A at a speed such that the trip from Earth to Star A takes 12 y according to clocks on the spaceship. At what speed, relative to Earth, must the spaceship travel? (Assume that the times for the accelerations are very short compared to the overall trip time.) (b) Upon reaching Star A, the spaceship speeds up and departs for Star B at a speed such that the gamma factor, γ, is twice that of Part (a). The trip from Star A to Star B takes 5.0 y (spaceship's time). How far, in c·y, is Star B from Star A in the rest frame of Earth and the two stars? (c) Upon reaching Star B, the spaceship departs for Earth at the same speed as in Part (b). It takes it 10 y (spaceship's time) to return to Earth. If you were born on Earth the day the ship left Earth and you remain on Earth, how old are you on the day the ship returns to Earth?

Picture the Problem We can use the time-dilation relationship to find the speed of the spacecraft. The distance to the second star is the product of the new gamma factor, the speed of the spacecraft, and the elapsed time. Finally, the time that has elapsed on Earth (your age) is the sum of the elapsed times for the three legs of the journey.

(a) From the point of view of an observer on Earth, the elapsed time for the trip will be:

$$\Delta t = \frac{L}{v}$$

From the point of view of an observer on the spaceship, the elapsed time for the trip will be:

$$\Delta t' = \frac{\Delta t}{\gamma} = \frac{L}{\gamma v}$$

Substitute for γ to obtain:

$$\Delta t' = \frac{L}{v}\sqrt{1-\frac{v^2}{c^2}} \Rightarrow v = \frac{Lc}{\sqrt{L^2 + c^2(\Delta t')^2}}$$

Substitute numerical values and evaluate v:

$$v = \frac{(27\,c\cdot\text{y})c}{\sqrt{(27\,c\cdot\text{y})^2 + c^2(12\,\text{y})^2}} = 0.914c$$
$$= \boxed{0.91c}$$

Note that from the point of view of an Earth observer, this part of the trip has taken 27 $c\cdot$y/0.914c = 29.5 y.

(b) The distance the ship travels, from the point of view of an Earth observer, in 5 y is:

$$\Delta L' = 2\gamma\Delta L = 2\gamma v\Delta t$$

where γ is the gamma factor for the first part of the trip.

The gamma factor in Part (a) is:

$$\gamma = \frac{1}{\sqrt{1-\left(\frac{v}{c}\right)^2}} = \frac{1}{\sqrt{1-\left(\frac{0.914c}{c}\right)^2}}$$
$$= 2.46$$

Substitute numerical values and evaluate $\Delta L'$:

$$\Delta L' = 2(2.46)(0.914c)(5.0\,\text{y})$$
$$= 22.5\,c\cdot\text{y} = \boxed{22\,c\cdot\text{y}}$$

(c) The elapsed time Δt on Earth (your age) is the sum of the times for the spacecraft to travel to the star 27 $c\cdot$y away, to the second star, and to return home from the second star:

$$\Delta t = 29.5\,\text{y} + 22.5\,\text{y} + \Delta t_{\substack{\text{returning}\\ \text{home}}}$$

The elapsed time on Earth while the spacecraft is returning to Earth is:

$$\Delta t_{\substack{\text{returning}\\ \text{home}}} = 2\gamma\Delta t_{\text{ship's time}}$$
$$= 2(2.46)(10\,\text{y})$$
$$= 49.2\,\text{y}$$

Substitute for $\Delta t_{\substack{\text{returning}\\ \text{home}}}$ and evaluate Δt:

$$\Delta t = 29.5\,\text{y} + 22.5\,\text{y} + 49.2\,\text{y}$$
$$= \boxed{101\,\text{y}}$$

12 • A spaceship travels to a star 35 $c\cdot$y away at a speed of 2.7×10^8 m/s. How long does the spaceship take to get to the star (a) as measured on Earth and (b) as measured by a passenger on the spaceship?

Picture the Problem We can use $\Delta t = L/v$, where L is the distance to the star and v is the speed of the spaceship to find the time Δt for the trip as measured on Earth. The travel time as measured by a passenger on the spaceship can be found using $\Delta t' = \Delta t/\gamma$.

(*a*) The travel time as measured on Earth is the ratio of the distance traveled L to speed of the spaceship:

$$\Delta t = \frac{L}{v}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{35c\cdot\text{y}}{2.7\times10^{8}\ \text{m/s}} = \frac{35\,\text{y}}{\dfrac{2.7\times10^{8}\ \text{m/s}}{c}}$$

$$= \frac{35\,\text{y}}{0.9} = 38.9\,\text{y} = \boxed{39\,\text{y}}$$

(*a*) The travel time as measured by a passenger on the spaceship is given by:

$$\Delta t' = \frac{\Delta t}{\gamma} = \Delta t\sqrt{1-\left(\frac{v}{c}\right)^{2}}$$

Substitute numerical values and evaluate $\Delta t'$:

$$\Delta t' = (38.9\,\text{y})\sqrt{1-(0.90)^{2}} = \boxed{17\,\text{y}}$$

13 •• [SSM] Unobtainium (Un) is an unstable particle that decays into normalium (Nr) and standardium (St) particles. (*a*) An accelerator produces a beam of Un that travels to a detector located 100 m away from the accelerator. The particles travel with a velocity of $v = 0.866c$. How long do the particles take (in the laboratory frame) to get to the detector? (*b*) By the time the particles get to the detector, half of the particles have decayed. What is the half-life of Un? (*Note:* half-life as it would be measured in a frame moving with the particles) (*c*) A new detector is going to be used, which is located 1000 m away from the accelerator. How fast should the particles be moving if half of the particles are to make it to the new detector?

Picture the Problem The time required for the particles to reach the detector, as measured in the laboratory frame of reference is the ratio of the distance they must travel to their speed. The half life of the particles is the trip time as measured in a frame traveling with the particles. We can find the speed at which the particles must move if they are to reach the more distant detector by equating their half life to the ratio of the distance to the detector in the particle's frame of reference to their speed.

(*a*) The time required to reach the detector is the ratio of the distance to the detector and the speed with which the particles are traveling:

$$\Delta t = \frac{\Delta x}{v} = \frac{\Delta x}{0.866c}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{100\,\text{m}}{0.866\left(2.998\times10^{8}\,\text{m/s}\right)} = \boxed{0.385\,\mu\text{s}}$$

(*b*) The half life is the trip time as measured in a frame traveling with the particles:

$$\Delta t' = \frac{\Delta t}{\gamma} = \Delta t\sqrt{1-\left(\frac{v}{c}\right)^2}$$

Substitute numerical values and evaluate $\Delta t'$:

$$\Delta t' = \left(0.385\,\mu\text{s}\right)\sqrt{1-\left(\frac{0.866c}{c}\right)^2} = \boxed{0.193\,\mu\text{s}}$$

(*c*) In order for half the particles to reach the detector:

$$\Delta t' = \frac{\Delta x'}{\gamma v} = \frac{\Delta x'\sqrt{1-\left(\frac{v}{c}\right)^2}}{v}$$

where $\Delta x'$ is the distance to the new detector.

Rewrite this expression to obtain:

$$\frac{v}{\sqrt{1-\left(\frac{v}{c}\right)^2}} = \frac{\Delta x'}{\Delta t'}$$

Squaring both sides of the equation yields:

$$\frac{v^2}{1-\left(\frac{v}{c}\right)^2} = \left(\frac{\Delta x'}{\Delta t'}\right)^2$$

Substitute numerical values for $\Delta x'$ and $\Delta t'$ and simplify to obtain:

$$\frac{v^2}{1-\left(\frac{v}{c}\right)^2} = \left(\frac{1000\,\text{m}}{0.193\,\mu\text{s}}\right)^2 = \left(17.3c\right)^2$$

Divide both sides of the equation by c^2 to obtain:

$$\frac{\frac{v^2}{c^2}}{1-\left(\frac{v}{c}\right)^2}=(17.3)^2$$

Solving this equation for v^2/c^2 gives:

$$\frac{v^2}{c^2}=\frac{(17.3)^2}{1+(17.3)^2}=0.9967$$

Finally, solving for v yields:

$$v=\boxed{0.998c}$$

14 •• A clock on Spaceship A measures the time interval between two events, both of which occur at the location of the clock. You are on Spaceship B. According to your careful measurements, the time interval between the two events is 1.00 percent longer than that measured by the two clocks on Spaceship A. How fast is Spaceship A moving relative to Spaceship B. (*Hint: Use one or more of the results of Problem 10.*)

Picture the Problem We can express the fractional difference in your time-interval measurements as a function of γ and solve the resulting equation for the relative speed of the two spaceships.

Express the fractional difference in the time-interval measurements of the two observers:

$$\frac{\Delta t-\Delta t'}{\Delta t}=1-\frac{\Delta t'}{\Delta t}=0.0100$$

Since $\Delta t'/\Delta t=1/\gamma$:

$$\frac{\Delta t-\Delta t'}{\Delta t}=1-\frac{1}{\gamma}=0.0100$$

From Problem 10(*b*) we have:

$$\frac{1}{\gamma}\approx 1-\frac{1}{2}\frac{v^2}{c^2}$$

Substitute to obtain:

$$1-\frac{1}{\gamma}\approx 1-\left(1-\frac{1}{2}\frac{v^2}{c^2}\right)=0.0100$$

or

$$\frac{1}{2}\frac{v^2}{c^2}=0.0100$$

Solve for v to obtain:

$$v=\sqrt{0.0200}c=0.141c$$

$$=\boxed{4.23\times10^7\ \text{m/s}}$$

15 •• If a plane flies at a speed of 2000 km/h, how long must the plane fly before its clock loses 1.00 s because of time dilation? (*Hint: Use one or more of the results of Problem 10.*)

Picture the Problem We can use the time dilation equation to relate the time lost by the clock to the speed of the plane and the time it must fly.

Express the time δt lost by the clock:

$$\delta t = \Delta t - \Delta t_{\text{p}} = \Delta t - \frac{\Delta t}{\gamma} = \Delta t\left(1 - \frac{1}{\gamma}\right)$$

Because $V << c$, we can use Part (*b*) of Problem 10:

$$\frac{1}{\gamma} \approx 1 - \frac{1}{2}\frac{V^2}{c^2}$$

Substitute to obtain:

$$\delta t = \Delta t\left[1 - \left(1 - \frac{1}{2}\frac{V^2}{c^2}\right)\right] = \frac{1}{2}\frac{V^2}{c^2}\Delta t$$

Solving for Δt gives:

$$\Delta t = \frac{2\delta t\, c^2}{V^2}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(1.00\,\text{s})(2.998\times10^8\ \text{m/s})^2}{(2000\,\text{km/h}\times1\,\text{h}/3600\,\text{s})^2}$$

$$= 5.824\times10^{11}\ \text{s}\times\frac{1\,\text{y}}{31.56\,\text{Ms}}$$

$$= \boxed{1.85\times10^4\ \text{y}}$$

The Lorentz Transformation, Clock Synchronization, and Simultaneity

16 •• Show that when $v << c$ the relativistic transformation equations for x, t, and u_x reduce to the classical transformation equations.

Picture the Problem We can use the inverse Lorentz transformations and the result of Problem 10(*c*) to show that when $u << c$ the transformation equations for x, t, and u reduce to the Galilean equations.

The inverse transformation for x is:

$$x' = \gamma(x - vt)$$

From Problem 10(*c*):

$$\gamma = 1 + \frac{1}{2}\frac{v^2}{c^2}$$

Substitute for γ and expand to obtain:

$$x' = \left(1 + \frac{1}{2}\frac{v^2}{c^2}\right)(x - vt)$$
$$= x - vt + \frac{1}{2}\frac{v^2}{c^2}x - \frac{1}{2}\frac{v^3}{c^2}t$$

When $v << c$:

$$\boxed{x' \approx x - vt}$$

The inverse transformation for t is:

$$t' = \gamma\left(t - \frac{vx}{c^2}\right)$$

Substitute for γ and expand to obtain:

$$t' = \left(1 + \frac{1}{2}\frac{v^2}{c^2}\right)\left(t - \frac{vx}{c^2}\right)$$
$$= t - \frac{vx}{c^2} + \frac{1}{2}\frac{v^2}{c^2}t - \frac{1}{2}\frac{v^3}{c^4}x$$

When $v << c$:

$$\boxed{t' \approx t}$$

The inverse velocity transformation for motion in the x direction is:

$$u_x' = \frac{u_x - v}{1 - \dfrac{vu_x}{c^2}}$$

When $v << c$:

$$\boxed{u_x' \approx u_x - v}$$

17 •• [SSM] A spaceship of proper length $L_p = 400$ m moves past a transmitting station at a speed of $0.760c$. (The transmitting station broadcasts signals that travel at the speed of light.) A clock is attached to the nose of the spaceship and a second clock is attached to the transmitting station. The instant that the nose of the spaceship passes the transmitter, the clock attached to the transmitter and the clock attached to the nose of the spaceship are set equal to zero. The instant that the tail of the spaceship passes the transmitter a signal is sent by the transmitter that is subsequently detected by a receiver in the nose of the spaceship. (*a*) When, according to the clock attached to the nose of spaceship, is the signal sent? (*b*) When, according to the clocks attached to the nose of spaceship, is the signal received? (*c*) When, according to the clock attached to the transmitter, is the signal received by the spaceship? (*d*) According to an observer that works at the transmitting station, how far from the transmitter is the nose of the spaceship when the signal is received?

Picture the Problem Let S be the reference frame of the spaceship and S' be that of Earth (transmitter station). Let event A be the emission of the light pulse and event B the reception of the light pulse at the nose of the spaceship. In (*a*) and (*c*)

we can use the classical distance, rate, and time relationship and in (*b*) and (*d*) we can apply the inverse Lorentz transformations.

(*a*) In both *S* and *S*′ the pulse travels at the speed *c*. Thus:

$$t_A = \frac{L_p}{v} = \frac{400\,\text{m}}{0.760\text{c}} = \boxed{1.76\,\mu\text{s}}$$

(*b*) The inverse time transformation is:

$$t_B' = \gamma\left(t - \frac{vx}{c^2}\right)$$

where

$$\gamma = \frac{1}{\sqrt{1-\dfrac{v^2}{c^2}}} = \frac{1}{\sqrt{1-\dfrac{(0.760c)^2}{c^2}}} = 1.54$$

Substitute numerical values and evaluate t_B':

$$t_B' = (1.54)\left(3.09\,\mu\text{s} - \frac{(-0.760c)(400\,\text{m})}{c^2}\right)$$

$$= (1.54)\left(3.09\,\mu\text{s} - \frac{(-0.760)(400\,\text{m})}{2.998\times10^8\ \text{m/s}}\right)$$

$$= \boxed{6.32\,\mu\text{s}}$$

(*c*) The elapsed time, according to the clock on the ship is:

$$t_B = t_{\substack{\text{pulse to travel}\\ \text{length of ship}}} + t_A$$

Find the time of travel of the pulse to the nose of the ship:

$$t_{\substack{\text{pulse to travel}\\ \text{length of ship}}} = \frac{400\,\text{m}}{2.998\times10^8\ \text{m/s}} = 1.33\,\mu\text{s}$$

Substitute numerical values and evaluate t_B:

$$t_B = 1.33\,\mu\text{s} + 1.76\,\mu\text{s} = \boxed{3.09\,\mu\text{s}}$$

(*d*) The inverse transformation for *x* is:

$$x' = \gamma(x - vt)$$

Substitute numerical values and evaluate x':

$$x' = (1.54)\left[400\,\text{m} - (-0.760)(2.998\times10^8\ \text{m/s})(3.09\times10^{-6}\ \text{s})\right] = \boxed{1.70\,\text{km}}$$

18 •• In frame S, event B occurs 2.0 μs after event A, and event A occurs at the origin whereas event B occurs on the x axis at x = 1.5 km. How fast and in what direction must an observer be traveling along the x axis so that events A and B occur simultaneously? Is it possible for event B to precede event A for some observer?

Picture the Problem We can use Equation 39-12, the inverse time transformation equation, to find the required speed of the observer.

Use Equation 39-12 to obtain:

$$\Delta t' = t_B' - t_A' = \gamma\left[(t_B - t_A) - \frac{v}{c^2}(x_B - x_A)\right] = \gamma\left(\Delta t - \frac{v\Delta x}{c^2}\right)$$

where $\Delta t = t_B - t_A$ and $\Delta x = x_B - x_A$.

Setting $\Delta t'$ equal to zero gives:

$$\Delta t - \frac{v\Delta x}{c^2} = 0 \Rightarrow v = \frac{c\Delta t}{\Delta x}c$$

Substitute numerical values and evaluate v:

$$v = \frac{(2.998\times10^8\ \text{m/s})(2.0\ \mu\text{s})}{1.5\,\text{km}}c = \boxed{0.40\text{c}}$$

Because $\Delta t = t_B - t_A = 2.0\ \mu$s :

$\boxed{\text{The observer is moving in the } +x \text{ direction.}}$

If B occurs before A, then $\Delta t' < 0$:

$$\Delta t' = \gamma\left(\Delta t - \frac{v\Delta x}{c^2}\right) < 0$$

and

$$\Delta t - \frac{v\Delta x}{c^2} < 0$$

Solving for v yields:

$$v > \frac{c^2\Delta t}{\Delta x} = 0.40c$$

Yes. Event B will precede event A for some observer (t'_B will be less than t'_A) provided $v > 0.40c$.

19 •• Observers in reference frame S see an explosion located on the x axis at x_1 = 480 m. A second explosion occurs, 5.0 μs later, at x_2 = 1200 m. In

reference frame S', which is moving along the x axis in the $+x$ direction at speed v, the two explosions occur at the same point in space. What is the separation in time between the two explosions as measured in S'?

Picture the Problem We can use Equation 39-12, the inverse time transformation equation, to express the separation in time $\Delta t'$ between the two explosions as measured in S' as a function of the speed v of the observer and Equation 39-11, the inverse position transformation equation, to find the speed of the observer.

Use Equation 39-12 to express the separation in time between the two explosions as measured in S':

$$\Delta t' = \gamma\left[\Delta t - \frac{v}{c^2}\Delta x\right]$$

$$= \frac{\Delta t - \dfrac{v}{c^2}\Delta x}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}} \qquad (1)$$

From Equation 39-11:

$$\Delta x' = \gamma(\Delta x - v\Delta t)$$

Because the explosions occur at the same point in space, $\Delta x' = 0$:

$$0 = \gamma(\Delta x - v\Delta t) \Rightarrow v = \frac{\Delta x}{\Delta t}$$

Substitute numerical values and evaluate v:

$$v = \frac{1200\,\text{m} - 480\,\text{m}}{5.0\,\mu\text{s}} = 1.44\times10^8\ \text{m/s}$$

Substitute numerical values in equation (1) and evaluate $\Delta t'$:

$$\Delta t' = \frac{5.0\,\mu\text{s} - \dfrac{1.44\times10^8\ \text{m/s}}{\left(2.998\times10^8\ \text{m/s}\right)^2}(1200\,\text{m} - 480\,\text{m})}{\sqrt{1-\left(\dfrac{1.44\times10^8\ \text{m/s}}{2.998\times10^8\ \text{m/s}}\right)^2}} = \boxed{4.4\,\mu\text{s}}$$

20 ••• In reference frame S, events 1 and 2 are separated by a distance $D = x_2 - x_1$ and a time $T = t_2 - t_1$. (*a*) Use the Lorentz transformation to show that in frame S', which is moving along the x axis with speed v relative to S, the time separation is $t_2' - t_1' = \gamma\left(T - vD/c^2\right)$. (*b*) Show that the events can be simultaneous in frame S' only if D is greater than cT. (*c*) If one of the events is the *cause* of the other, the separation D must be less than cT, because D/c is the smallest time that a signal can take to travel from x_1 to x_2 in frame S. Show that if D is less than cT, t_2' is greater than t_1' in all reference frames. This shows that if the cause precedes the effect in one frame, it must precede it in all reference

frames. (*d*) Suppose that a signal could be sent with speed $c' > c$ so that in frame S the cause precedes the effect by the time $T = D/c'$. Show that there is then a reference frame moving with speed v less than c in which the effect precedes the cause.

Picture the Problem We can use Equation 39-12, the inverse time transformation equation, to establish the results called for in this problem.

(*a*) Use Equation 39-12 to obtain:

$$t_2' - t_1' = \gamma\left[(t_2 - t_1) - \frac{v}{c^2}(x_2 - x_1)\right] = \boxed{\gamma\left(T - \frac{vD}{c^2}\right)}$$

where $T = t_2 - t_1$ and $D = x_2 - x_1$.

(*b*) Events 1 and 2 are simultaneous in S' if:

$$t_2' = t_1'$$

or

$$T - \frac{vD}{c^2} = 0 \Rightarrow D = \frac{c^2T}{v}$$

Because $v \leq c$:

$$D \geq \boxed{cT}$$

(*c*) If $D < cT$, then $t_2' > t_1'$ and the events are not simultaneous in S'.

(*d*) If $D = c'T > cT$, then:

$$T - \frac{vD}{c^2} = T\left[1 - \frac{v}{c}\frac{c'}{c}\right] = t_2' - t_1'$$

In this case, $t_2' > t_1'$ could be negative; i.e., t_2' could be less than t_1', or the effect could precede the cause.

21 ••• A rocket that has a proper length of 700 m is moving to the right at a speed of 0.900*c*. It has two clocks—one in the nose and one in the tail—that have been synchronized in the frame of the rocket. A clock on the ground and the clock in the nose of the rocket both read zero as they pass by each other. (*a*) At the instant the clock on the ground reads zero, what does the clock in the tail of the rocket read according to observers on the ground? When the clock in the tail of the rocket passes the clock on the ground, and (*b*) what does the clock in the tail read according to observers on the ground, (*c*) what does the clock in the nose read according to observers on the ground, and (*d*) what does the clock in the nose read according to observers on the rocket? (*e*) At the instant the clock in the nose of the rocket reads 1.00 h, a light signal is sent from the nose of the rocket to an observer standing by the clock on the ground. What does the clock on the ground read when the observer on the ground receives this signal? (*f*) When the observer

on the ground receives the signal, he immediately sends a return signal to the nose of the rocket. What is the reading of the clock in the nose of the rocket when this signal is received at the nose of the rocket?

Picture the Problem Let S be the ground reference frame, S' the reference frame of the rocket, and $v = 0.900c$ be the speed of the rocket relative to S. Denote the tail and nose of the rocket by T and N, respectively. The initial conditions in S' are $t_N' = 0$, $x_N' = 0$, and $x_T' = -L' = -700\,\text{m}$.

(*a*) The reading of the tail clock is given by:

$$t_T' = \gamma\left(t_T - \frac{vx_T}{c^2}\right) = -\frac{\gamma v x_T}{c^2}$$

because $t_T = 0$

We can find x_T using the length contraction equation:

$$x_T = -\frac{L'}{\gamma}$$

Substitute for x_T to obtain:

$$t_T' = \frac{vL'}{c^2}$$

Substitute numerical values and evaluate t_T':

$$t_T' = \frac{(0.900)(700\,\text{m})}{2.998\times10^8\ \text{m/s}} = 2.101\,\mu\text{s}$$

$$= \boxed{2.10\,\mu\text{s}}$$

(*b*) The time for the rocket to move a distance L' is given by:

$$t_T' = \frac{L'}{v} = \frac{L'}{0.9c}$$

Substitute numerical values and evaluate t_T':

$$t_T' = \frac{700\,\text{m}}{(0.900)(2.998\times10^8\ \text{m/s})}$$

$$= 2.594\,\mu\text{s} = \boxed{2.59\,\mu\text{s}}$$

(*c*) As seen by an observer on the ground:

$$t_N = \Delta t' = 2.59\,\mu\text{s} - 2.10\,\mu\text{s}$$

$$= \boxed{0.49\,\mu\text{s}}$$

(*d*) Because the clocks are synchronized in S':

$$t_N' = t_T' = \boxed{2.59\,\mu\text{s}}$$

(*e*) The time the signal is received on the ground is the sum of the time when the signal is sent and the time for it to travel to the ground:

$$t_{\text{rec}} = \Delta t + \Delta t_{\text{travel}}$$

Find Δt, the time the signal is sent:

$$\Delta t = \gamma \Delta t_{\text{p}} = \frac{1.00\,\text{h}}{\sqrt{1-\frac{(0.900c)^2}{c^2}}} = 2.294\,\text{h}$$

Find Δt_{travel}, the time for the signal to travel to the ground:

$$\Delta t_{\text{travel}} = \frac{\Delta x}{c} = \frac{(2.294\,\text{h})(0.900c)}{c} = 2.065\,\text{h}$$

Substitute for Δt and Δt_{travel} and evaluate t_{rec}:

$$t_{\text{rec}} = 2.294\,\text{h} + 2.065\,\text{h} = 4.359\,\text{h} = \boxed{4.36\,\text{h}}$$

(*f*) Find Δx when the signal is sent:

$$\Delta x = (4.359\,\text{h})(0.900c) = 3.923\,c\cdot\text{h}$$

In *S,* the signal arrives at $0.1c$ relative to the rocket. The time required for the signal to travel to the rocket is:

$$\Delta t = \frac{\Delta x}{0.100c} = \frac{3.923\,c\cdot\text{h}}{0.100c} = 39.23\,\text{h}$$

Find the time when the signal reaches the rocket:

$$t = 39.23\ \text{h} + 3.923\ \text{h} = 43.15\ \text{h}$$

Finally, use the time dilation equation to find $t_N{}'$:

$$t_N{}' = \frac{t}{\gamma} = (43.15\,\text{h})\sqrt{1-\frac{(0.900c)^2}{c^2}} = \boxed{18.8\,\text{h}}$$

The Velocity Transformation

22 •• A spaceship, at rest in a certain reference frame *S*, is given a speed increase of $0.50c$ (call this increase boost 1). Relative to its new rest frame, the spaceship is given a further $0.50c$ increase 10 seconds later (as measured in its new rest frame; call this increase boost 2). This process is continued indefinitely, at 10-s intervals, as measured in the rest frame of the spaceship. (Assume that the boosts take a very short time compared to 10 s.) (*a*) Using a **spreadsheet** program, calculate and graph the speed of the spaceship in reference frame *S* as a

function of the boost number for boost 1 to boost 10. (*b*) Graph the gamma factor the same manner. (*c*) How many boosts does it take until the speed of the ship in *S* is greater than 0.999*c*? (*d*) How far does the spaceship move between boost 1 and boost 6, as measured in reference frame *S*? What is the average speed of the spaceship between boost 1 and boost 6, as measured in *S*?

Picture the Problem We'll let the speed (in *S*) of the spaceship after the i^th boost be v_i and derive an expression for the ratio of v to c after the spaceship's $(i + 1)$th boost as a function of the number of boosts *N*. We can use the definition of γ, in terms of v/c to plot γ as a function of *N*.

(*a*) and (*b*) The speed of the spaceship after the $(i + 1)$th boost is given by relativistic velocity addition equation:

$$v_{i+1}=\frac{v_i+0.50c}{1+\frac{(0.50c)v_i}{c^2}}$$

Factor c from both the numerator and denominator to obtain:

$$v_{i+1}=\frac{\frac{v_i}{c}+0.50}{1+(0.50)\frac{v_i}{c}}$$

γ_i is given by:

$$\gamma_i=\frac{1}{\sqrt{1-\left(\frac{v_i}{c}\right)}}$$

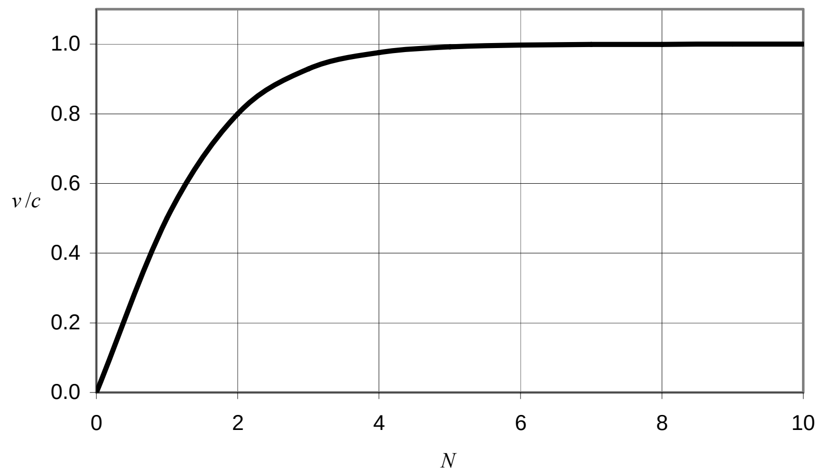
A spreadsheet program to calculate v/c and γ as functions of the number of boosts *N* is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A3	0	N
B2	0	v_0
B3	(B2+0.5)/(1+0.5*B2)	v_{i+1}
C1	1/(1−B2^2)^0.5	γ

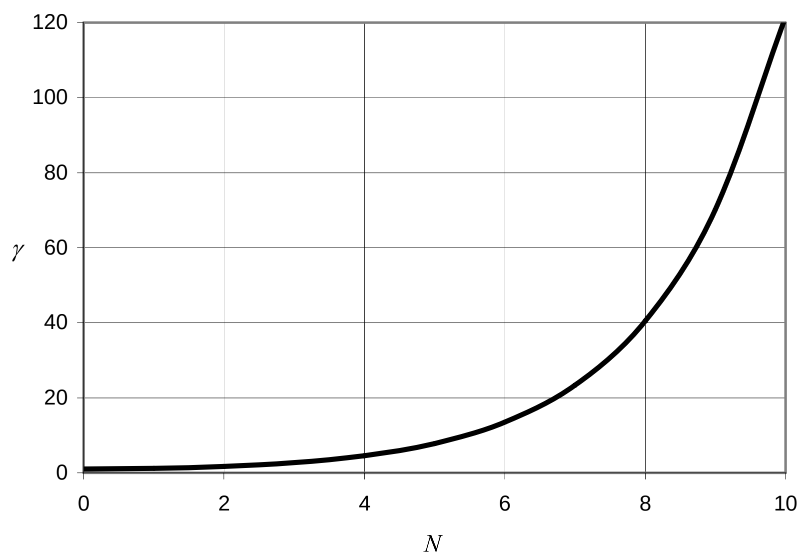
	A	B	C
1	N	v/c	γ
2	0	0.000	1.00
3	1	0.500	1.15
4	2	0.800	1.67
5	3	0.929	2.69
6	4	0.976	4.56
7	5	0.992	7.83
8	6	0.997	13.52
9	7	0.999	23.39

10	8	1.000	40.51
11	9	1.000	70.15
12	10	1.000	121.50

A graph of v/c as a function of N follows:



A graph of γ as a function of N follows:



(c) Examination of the spreadsheet or of the graph of v/c as a function of N indicates that, after 8 boosts, the speed of the spaceship is greater than $0.999c$.

(*d*) After 5 boosts, the spaceship has traveled a distance Δx, measured in the Earth frame of reference (S), given by:

$$\begin{aligned}\Delta x &= \Delta x_{1\to2} + \Delta x_{2\to3} + \Delta x_{3\to4} + \Delta x_{4\to5} + \Delta x_{5\to6} \\ &= (0.5c)(10\,\text{s})\gamma_{1\to2} + (0.8c)(10\,\text{s})\gamma_{2\to3} + (0.929c)(10\,\text{s})\gamma_{3\to4} \\ &\quad + (0.976c)(10\,\text{s})\gamma_{4\to5} + (0.992c)(10\,\text{s})\gamma_{5\to6} \\ &= (0.5c)(10\,\text{s})(1.15) + (0.8c)(10\,\text{s})(1.67) + (0.929c)(10\,\text{s})(2.69) \\ &\quad + (0.976c)(10\,\text{s})(4.56) + (0.992c)(10\,\text{s})(7.83) \\ &= \boxed{166c\cdot\text{s}}\end{aligned}$$

The average speed of the spaceship, between boost 1 and boost 5, as measured in S is given by:

$$v_{\text{av}} = \frac{\Delta x}{\Delta t}$$

where Δt is the travel time as measured in the Earth frame of reference.

Express Δt as the sum of the times the spaceship travels during each 10-s interval following a boost in its speed:

$$\begin{aligned}\Delta t &= \Delta t_{1\to2} + \Delta t_{2\to3} + \Delta t_{3\to4} + \Delta t_{4\to5} + \Delta t_{5\to6} \\ &= (10\,\text{s})\gamma_{1\to2} + (10\,\text{s})\gamma_{2\to3} + (10\,\text{s})\gamma_{3\to4} + (10\,\text{s})\gamma_{4\to5} + (10\,\text{s})\gamma_{5\to6} \\ &= (10\,\text{s})(\gamma_{1\to2} + \gamma_{2\to3} + \gamma_{3\to4} + \gamma_{4\to5} + \gamma_{5\to6})\end{aligned}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = (10\,\text{s})(1.15 + 1.67 + 2.69 + 4.56 + 7.83) = 179\,\text{s}$$

Substitute for Δx and Δt and evaluate v_{av}:

$$v_{\text{av}} = \frac{166c\cdot\text{s}}{179\,\text{s}} = \boxed{0.927c}$$

Remarks: This result seems to be reasonable. Relativistic time dilation implies that the spacecraft will be spending larger amounts of time at high speed (as seen in reference frame *S*).

The Relativistic Doppler Shift

23 • Light is emitted by a sodium sample that is moving toward Earth with speed v. The wavelength of the light is 589 nm in the rest frame of the sample. The wavelength measured in the frame of Earth is 547 nm. Find v.

Picture the Problem We can substitute, using $c = f\lambda$, in the relativistic Doppler shift equation and solve for the speed of the source.

Using the expression for the relativistic Doppler shift, express f' as a function of v:

$$f' = f\sqrt{\frac{1+v/c}{1-v/c}}$$

Substitute using $c = f\lambda$ and simplify to obtain:

$$\frac{c}{\lambda'} = \frac{c}{\lambda}\sqrt{\frac{1+v/c}{1-v/c}} \Rightarrow \frac{\lambda}{\lambda'} = \sqrt{\frac{1+v/c}{1-v/c}}$$

or

$$\left(\frac{\lambda}{\lambda'}\right)^2 = \frac{1+v/c}{1-v/c}$$

Solving for v gives:

$$v = \left[\frac{\left(\frac{\lambda}{\lambda'}\right)^2 - 1}{\left(\frac{\lambda}{\lambda'}\right)^2 + 1}\right]c$$

Substitute numerical values and evaluate v:

$$v = \left[\frac{\left(\frac{589\,\text{nm}}{547\,\text{nm}}\right)^2 - 1}{\left(\frac{589\,\text{nm}}{547\,\text{nm}}\right)^2 + 1}\right]\left(2.998\times10^8\ \text{m/s}\right) = \boxed{2.22\times10^7\ \text{m/s}}$$

24 • A distant galaxy is moving away from us at a speed of 1.85×10^7 m/s. Calculate the fractional redshift $(\lambda' - \lambda_0)/\lambda_0$ that we observe the light from this galaxy to have.

Picture the Problem We can use the relativistic Doppler shift, when the source and the receiver are receding, to relate the frequencies of the two wavelengths and $c = f\lambda$ to express the ratio of the wavelengths as a function of the speed of the galaxy.

When the source and receiver are moving away from each other, the relativistic Doppler shift is given by:

$$f' = \sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}}\,f_0$$

Use the relationship between the wavelength and frequency to obtain:

$$\frac{c}{\lambda'} = \sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}}\,\frac{c}{\lambda_0} \Rightarrow \frac{\lambda_0}{\lambda'} = \sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}}$$

Solving for λ'/λ_0 yields:

$$\frac{\lambda'}{\lambda_0}=\sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}}$$

Express the fractional redshift:

$$\frac{\lambda'-\lambda_0}{\lambda_0}=\frac{\lambda'}{\lambda_0}-1=\sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}}-1$$

Substitute numerical values and evaluate $(\lambda'-\lambda_0)/\lambda_0$:

$$\frac{\lambda'-\lambda_0}{\lambda_0}=\sqrt{\frac{1+\frac{1.85\times10^7\text{ m/s}}{2.998\times10^8\text{ m/s}}}{1-\frac{1.85\times10^7\text{ m/s}}{2.998\times10^8\text{ m/s}}}}-1$$

$$=\boxed{0.0637}$$

25 •• Derive $f'=f_0\sqrt{1-\left(v^2/c^2\right)}\Big/\left[1-\left(v/c\right)\right]$ (Equation **Error! Reference source not found.**a) for the frequency received by an observer moving with speed v toward a stationary source of electromagnetic waves.

Picture the Problem We can begin the derivation by expressing the number of waves received by the observer, in the rest frame of the source, in a time interval Δt. We can then relate this time interval to the time interval in the rest frame of the observer to complete the derivation of Equation 39-16a.

Express the number of waves n encountered by the observer, in the rest frame of the source, in a time interval Δt_s:

$$n=\frac{(c+v)\Delta t_s}{\lambda}=\frac{(c+v)f_o\Delta t_s}{c}$$
$$=f_o\left(1+\frac{v}{c}\right)\Delta t_s$$

This time interval in the rest frame of the observer is given by:

$$\Delta t_o=\frac{\Delta t_s}{\gamma}$$

Express the frequency received by the observer and simplify to obtain:

$$f'=\frac{n}{\Delta t_o}=\gamma\left(1+\frac{v}{c}\right)f_o=\frac{1+\frac{v}{c}}{\sqrt{1-\frac{v^2}{c^2}}}f_o=\sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}}f_o=\boxed{\frac{\sqrt{1-\frac{v^2}{c^2}}}{1-\frac{v}{c}}f_o}$$

26 • Show that if v is much less than c, the Doppler shift is given approximately by $\Delta f/f \approx \pm v/c$.

Picture the Problem We can use the expression for the relativistic Doppler shift to show that, to a good approximation, $\Delta f/f \approx \pm v/c$.

Express the fractional Doppler shift in terms of f and f_0:

$$\frac{\Delta f}{f_0} = \frac{f - f_0}{f_0} = \frac{f}{f_0} - 1$$

When the source and receiver are approaching each other, the relativistic Doppler shift is given by:

$$f = \sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}}\, f_0 \Rightarrow \frac{f}{f_0} = \sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}}$$

Substitute in the expression for $\Delta f/f_0$ to obtain:

$$\frac{\Delta f}{f_0} = \sqrt{\frac{1+\frac{v}{c}}{1-\frac{v}{c}}} - 1$$

$$= \left(1+\frac{v}{c}\right)^{1/2}\left(1-\frac{v}{c}\right)^{-1/2} - 1$$

Keeping just the lowest order terms in v/c, expand binomially to obtain:

$$\frac{\Delta f}{f_0} = \left(1+\frac{1}{2}\frac{v}{c}\right)\left(1+\frac{1}{2}\frac{v}{c}\right) - 1$$

$$\approx 1 + \frac{v}{c} - 1 = \boxed{\frac{v}{c}}$$

The sign depends on whether the source and receiver are approaching or receding. Here we have assumed that they are approaching.

27 •• **[SSM]** A clock is placed in a satellite that orbits Earth with an orbital period of 90 min. By what time interval will this clock differ from an identical clock on Earth after 1.0 y? (Assume that special relativity applies and neglect general relativity.)

Picture the Problem Due to its motion, the orbiting clock will run more slowly than the Earth-bound clock. We can use Kepler's third law to find the radius of the satellite's orbit in terms of its period, the definition of speed to find the orbital speed of the satellite from the radius of its orbit, and the time dilation equation to find the difference δ in the readings of the two clocks.

Express the time δ lost by the clock:

$$\delta = \Delta t - \Delta t_{\mathrm{p}} = \Delta t - \frac{\Delta t}{\gamma} = \Delta t\left(1 - \frac{1}{\gamma}\right)$$

Because $v << c$, we can use Part (b) of Problem 10:

$$\frac{1}{\gamma} \approx 1 - \frac{1}{2}\frac{v^2}{c^2}$$

Substitute to obtain:

$$\delta = \Delta t\left[1 - \left(1 - \frac{1}{2}\frac{v^2}{c^2}\right)\right] = \frac{1}{2}\frac{v^2}{c^2}\Delta t \qquad (1)$$

Express the square of the speed of the satellite in its orbit:

$$v^2 = \left(\frac{2\pi r}{T}\right)^2 = \frac{4\pi^2 r^2}{T^2} \qquad (2)$$

where T is its period and r is the radius of its (assumed) circular orbit.

Use Kepler's third law to relate the period of the satellite to the radius of its orbit about Earth:

$$T^2 = \frac{4\pi^2}{GM_{\mathrm{E}}} r^3 = \frac{4\pi^2}{gR_{\mathrm{E}}^2} r^3 \Rightarrow r = \sqrt[3]{\frac{gR_{\mathrm{E}}^2 T^2}{4\pi^2}}$$

Substitute numerical values and evaluate r:

$$r = \sqrt[3]{\frac{(9.81\,\mathrm{m/s^2})(6370\,\mathrm{km})^2(90\,\mathrm{min} \times 60\,\mathrm{s/min})^2}{4\pi^2}} = 6.65 \times 10^6\,\mathrm{m}$$

Substitute numerical values in equation (2) and evaluate v^2:

$$v^2 = \frac{4\pi^2(6.65 \times 10^6\,\mathrm{m})^2}{(90\,\mathrm{min} \times 60\,\mathrm{s/min})^2} = 5.99 \times 10^7\,\mathrm{m^2/s^2}$$

Finally, substitute for v^2 in equation (1) and evaluate δ:

$$\delta = \frac{1}{2}\frac{(5.99 \times 10^7\,\mathrm{m^2/s^2})(1.0\,\mathrm{y} \times 31.56\,\mathrm{Ms/y})}{(2.998 \times 10^8\,\mathrm{m/s})^2} = \boxed{11\,\mathrm{ms}}$$

28 •• For light that is Doppler-shifted with respect to an observer, we define the redshift parameter $z = (f - f')/f'$, where f is the frequency of the light measured in the rest frame of the emitter, and f' is the frequency measured in the rest frame of the receiver. If the emitter is moving directly away from the receiver, show that the relative velocity between the emitter and the receiver is $v = c(u^2 - 1)/(u^2 + 1)$, where $u = z + 1$.

Picture the Problem We can use the definition of the redshift parameter and the relativistic Doppler shift equation to show that $v = c\left(\dfrac{u^2-1}{u^2+1}\right)$, where $u = z + 1$.

The red-shift parameter is defined to be:

$$z = \frac{f_0 - f'}{f'}$$

The relativistic Doppler shift for recessional motion is given by:

$$f' = f_0\sqrt{\frac{1-v/c}{1+v/c}}$$

Substitute for f' and simplify to obtain:

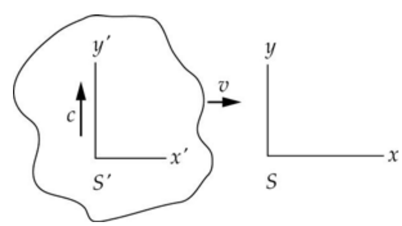
$$z = \frac{f_0 - f_0\sqrt{\dfrac{1-v/c}{1+v/c}}}{f_0\sqrt{\dfrac{1-v/c}{1+v/c}}} = \sqrt{\frac{1+v/c}{1-v/c}} - 1$$

Letting $u = z + 1$:

$$u = z + 1 = \sqrt{\frac{1+v/c}{1-v/c}} \Rightarrow v = \boxed{c\left(\frac{u^2-1}{u^2+1}\right)}$$

29 • A light beam moves along the y' axis with speed c in frame S', which is moving to the in the $+x$ direction with speed v relative to frame S. (*a*) Find the x and y components of the velocity of the light beam in frame S. (*b*) Show that, according to the velocity transformation equations, the magnitude of the velocity of the light beam in S is c.

Picture the Problem We can use the velocity transformation equations for the x and y directions to express the x and y components of the velocity of the light beam in frame S.



(*a*) The x and y components of the velocity of the light beam in frame S are:

$$u_x = \frac{u_x' + v}{1 + \dfrac{vu_x'}{c^2}} \text{ and } u_y = \frac{u_y'}{\gamma\left(1 + \dfrac{vu_x'}{c^2}\right)}$$

Because $u_x' = 0$:

$$u_x = \boxed{v} \text{ and } u_y = \boxed{\frac{c}{\gamma}}$$

(*b*) The magnitude of the velocity of the light beam in *S* is given by:

$$u = \sqrt{u_x^2 + u_y^2} = \sqrt{v^2 + \frac{c^2}{\gamma^2}}$$

$$= \sqrt{v^2 + \left(1 - \frac{v^2}{c^2}\right)c^2} = \boxed{c}$$

30 •• A spaceship is moving east at speed 0.90c relative to Earth. A second spaceship is moving west at speed 0.90c relative to Earth. What is the speed of one spaceship relative to the other spaceship?

Picture the Problem Let S be the Earth reference frame and S' be that of the ship traveling East (+x direction). Then in the reference frame S', the velocity of S is directed West, i.e., $v = -u_x$. We can apply the inverse velocity transformation equation to express u'_x in terms of u_x.

Apply the inverse velocity transformation equation to obtain:

$$u_x' = \frac{u_x - v}{1 - \frac{vu_x}{c^2}}$$

Substituting for v gives:

$$u_x' = \frac{u_x + u_x}{1 + \frac{u_x^2}{c^2}} = \frac{2u_x}{1 + \frac{u_x^2}{c^2}}$$

Because $u_x = 0.90c$:

$$u_x' = \frac{2(0.90c)}{1 + \frac{(0.90c)^2}{c^2}} = \boxed{0.99c}$$

31 •• **[SSM]** A particle moves with speed 0.800c in the $+x''$ direction along the x'' axis of frame S'', which moves with the same speed and in the same direction along the x' axis relative to frame S'. Frame S' moves with the same speed and in the same direction along the x axis relative to frame S. (*a*) Find the speed of the particle relative to frame S'. (*b*) Find the speed of the particle relative to frame S.

Picture the Problem We can apply the inverse velocity transformation equation to express the speed of the particle relative to both frames of reference.

(*a*) Express u_x' in terms of u_x'':

$$u_x' = \frac{u_x'' + v}{1 + \frac{vu_x''}{c^2}}$$

where v of S', relative to S'', is 0.800c.

Substitute numerical values and evaluate u_x':

$$u_x' = \frac{0.800c + 0.800c}{1 + \frac{(0.800c)^2}{c^2}} = \frac{1.60c}{1.64} = \boxed{0.976c}$$

(*b*) Express u_x in terms of u_x':

$$u_x = \frac{u_x' + v}{1 + \frac{v u_x'}{c^2}}$$ where v, the speed of S, relative to S', is $0.800c$.

Substitute numerical values and evaluate u_x:

$$u_x = \frac{0.976c + 0.800c}{1 + \frac{(0.800c)(0.976c)}{c^2}} = \frac{1.776c}{1.781} = \boxed{0.997c}$$

Relativistic Momentum and Relativistic Energy

32 • A proton that has a rest energy equal to 938 MeV has a total energy of 2200 MeV. (*a*) What is its speed? (*b*) What is its momentum?

Picture the Problem We can use the relation for the total energy, momentum, and rest energy to find the momentum of the proton and Equation 39-25 to relate the speed of the proton to its energy and momentum.

Relate the energy of the proton to its momentum:

$$E^2 = p^2c^2 + (mc^2)^2$$

(*b*) Solving for p gives:

$$p = \sqrt{\frac{E^2 - (mc^2)^2}{c^2}}$$

Substitute numerical values and evaluate p:

$$p = \frac{\sqrt{(2200\,\text{MeV})^2 - (938\,\text{MeV})^2}}{c} = \boxed{1.99\frac{\text{GeV}}{c}}$$

(*a*) From Equation 39-25 we have:

$$\frac{v}{c} = \frac{pc}{E} \Rightarrow v = \frac{pc}{E}c$$

Substitute numerical values and evaluate v:

$$v = \frac{1.99\,\text{GeV}}{2200\,\text{MeV}}c = \boxed{0.905c}$$

33 • If the kinetic energy of a particle equals twice its rest energy, what percentage error is made by using $p = mu$ for the magnitude of its momentum?

Picture the Problem We can use $E^2 = p^2c^2 + (mc^2)^2$ (Equation R-17) to find the relativistic momentum of the particle in terms of γ and the fact that the kinetic energy of the particle equals twice its rest energy to find the error made in using mv for the momentum of the particle.

Express the error e in using $p' = mv$ for the momentum of the particle:

$$e = \frac{p - p'}{p} = 1 - \frac{p'}{p} \qquad (1)$$

The relationship between the total energy E, momentum p, and rest energy mc^2 of the particle is:

$$E^2 = p^2c^2 + (mc^2)^2 \qquad \text{R-17}$$

Solve for p and simplify to obtain:

$$p = \sqrt{\frac{E^2}{c^2} - m^2c^2} = \sqrt{m^2c^2\left(\frac{E^2}{m^2c^4} - 1\right)}$$

Because $E = \gamma mc^2$:

$$p = mc\sqrt{\gamma^2 - 1}$$

Substitute for p and p' in equation (1) to obtain:

$$e = 1 - \frac{mu}{mc\sqrt{\gamma^2 - 1}} = 1 - \frac{u}{c\sqrt{\gamma^2 - 1}} \qquad (2)$$

From the definition of γ:

$$\frac{u}{c} = \sqrt{1 - \frac{1}{\gamma^2}}$$

Eliminate v/c in equation (2) to obtain:

$$e = 1 - \frac{1}{\sqrt{\gamma^2 - 1}}\sqrt{1 - \frac{1}{\gamma^2}} = 1 - \frac{1}{\gamma} \qquad (3)$$

The kinetic energy of the particle is related to its rest energy:

$$K = (\gamma - 1)mc^2 \Rightarrow \gamma = 1 + \frac{K}{mc^2}$$

Because the kinetic energy of the particle is twice its rest energy:

$$\gamma = 1 + \frac{2mc^2}{mc^2} = 3$$

Substitute for γ in equation (3) and evaluate e:

$$e = 1 - \frac{1}{3} = 0.667 = \boxed{66.7\%}$$

34 •• In a certain reference frame, a particle has momentum of 6.00 MeV/c and total energy of 8.00 MeV. (a) Determine the mass of the particle. (b) What is the total energy of the particle in a reference frame in which its momentum is 4.00 MeV/c? (c) What is the relative speed of the two reference frames?

Picture the Problem (a) The mass of the particle is given by $m = E_0/c^2$. (b) We can use Equation R-17 [$E^2 = p^2c^2 + \left(mc^2\right)^2$] to find the total energy of the particle in a reference frame in which its momentum is 4.00 MeV/c. (c) We can apply the inverse velocity transformation equation to find the relative speeds of the two reference frames.

(a) The mass of the particle is given by:

$$m = \frac{E_0}{c^2}$$

Substituting numerical values yields:

$$m = \frac{(8.00\,\text{MeV})\left(1.602\times10^{-19}\,\text{J/eV}\right)}{\left(2.998\times10^{8}\ \text{m/s}\right)^2} = \boxed{1.43\times10^{-29}\ \text{kg}}$$

(b) Solving equation R-17 for E gives:

$$E = \sqrt{p^2c^2 + \left(mc^2\right)^2} = \sqrt{p^2c^2 + E_0^2} \quad (1)$$

We can use Equation R-17 to find the energy of the particle in the reference frame in which it has momentum of 6.00 MeV/c and total energy of 8.00 MeV:

$$E^2 = p^2c^2 + E_0^2 \Rightarrow E_0 = \sqrt{E^2 - p^2c^2}$$

Substitute numerical values and evaluate E_0:

$$E_0 = \sqrt{(8.00\,\text{MeV})^2 - (6.00\,\text{MeV}/c)^2c^2} = \sqrt{(8.00\,\text{MeV})^2 - (6.00\,\text{MeV})^2} = 5.292\,\text{MeV}$$

Substitute numerical values in equation (1) and evaluate the total energy E of the particle:

$$E = \sqrt{(4.00\,\text{MeV}/c)^2c^2 + (5.292\,\text{MeV})^2} = \boxed{6.63\,\text{MeV}}$$

(c) The inverse speed transformation is:

$$u_b = \frac{u_a - v}{1 - \dfrac{vu_a}{c^2}}$$

where the subscripts refer to the speeds in Parts (a) and (b) of the problem.

Solving for v gives:

$$v=\frac{u_a-u_b}{1-\frac{u_a u_b}{c^2}} \qquad (1)$$

Relate the relativistic energy of the particle in (*a*) to its speed:

$$E=\frac{E_0}{\sqrt{1-\frac{u_a^2}{c^2}}}\Rightarrow u_a=c\sqrt{1-\left(\frac{E_0}{E}\right)^2}$$

Substitute numerical values and evaluate u_a:

$$u_a=c\sqrt{1-\left(\frac{5.292\,\text{MeV}}{8.00\,\text{MeV}}\right)^2}=0.7499c$$

Relate the relativistic momentum of the particle in (*b*) to its speed:

$$p=\frac{m_0u_b}{\sqrt{1-\frac{u_b^2}{c^2}}}\Rightarrow u_b=\frac{pc}{\sqrt{p^2+m_0c^2}}$$

Substitute numerical values and evaluate u_b:

$$u_b=\frac{(4.00\,\text{MeV}/c)c}{\sqrt{(4.00\,\text{MeV}/c)^2+(5.292\,\text{MeV}/c)^2}}=0.6030c$$

Substitute in equation (1) and evaluate v:

$$v=\frac{0.7499c-0.6030c}{1-\frac{(0.7499c)(0.6030c)}{c^2}}=\boxed{0.268c}$$

35 •• Show that $d\left(\frac{m_0u}{\sqrt{1-u^2/c^2}}\right)=m_0\left(1-\frac{u^2}{c^2}\right)^{-3/2}du$. *Note*: This relationship was used to derive the relativistically correct expression for kinetic energy (Equation 39-22).

Picture the Problem We can use the rule for the derivative of a quotient to establish the result given in the problem statement.

Use the expression for the derivative of a quotient to obtain:

$$\frac{d}{du}\left(\frac{mu}{\sqrt{1-u^2/c^2}}\right)=\frac{\sqrt{1-\frac{u^2}{c^2}}m+\frac{mu^2}{c^2}\frac{1}{\sqrt{1-\frac{u^2}{c^2}}}}{1-\frac{u^2}{c^2}}$$

Multiply the numerator and denominator of the right-hand side of this expression by $\sqrt{1-\frac{u^2}{c^2}}$ and simplify to obtain:

$$\frac{d}{du}\left(\frac{mu}{\sqrt{1-u^2/c^2}}\right)=\frac{\sqrt{1-\frac{u^2}{c^2}}\sqrt{1-\frac{u^2}{c^2}}m+\frac{mu^2}{c^2}\frac{\sqrt{1-\frac{u^2}{c^2}}}{\sqrt{1-\frac{u^2}{c^2}}}}{\left(1-\frac{u^2}{c^2}\right)\sqrt{1-\frac{u^2}{c^2}}}=\frac{\left(1-\frac{u^2}{c^2}\right)m+\frac{mu^2}{c^2}}{\left(1-\frac{u^2}{c^2}\right)^{3/2}}$$

$$=m\left(1-\frac{u^2}{c^2}\right)^{-3/2}$$

and

$$d\left(\frac{mu}{\sqrt{1-u^2/c^2}}\right)=\boxed{m\left(1-\frac{u^2}{c^2}\right)^{-3/2}du}$$

36 •• The K^0 particle has a mass of 497.7 MeV/c^2. It decays into a π^- and π^+, each having mass 139.6 MeV/c^2. Following the decay of a K^0, one of the pions is at rest in the laboratory. Determine the kinetic energy of the other pion after the decay and of the K^0 prior to the decay.

Picture the Problem We will first consider the decay process in the center of mass reference frame and then transform to the laboratory reference frame in which one of the pions is at rest.

Apply energy conservation in the center of mass frame of reference to obtain:

$$m_{K_0}c^2=2m_{\pi_0}\gamma c^2\Rightarrow\gamma=\frac{m_{K_0}}{2m_{\pi_0}}$$

Substitute numerical values and evaluate γ:

$$\gamma=\frac{497.7\,\text{MeV}/c^2}{2\left(139.6\,\text{MeV}/c^2\right)}=1.783$$

Because one of the pions is at rest in the laboratory frame, γ = 1.78 for the transformation to the laboratory frame. The kinetic energy of the K^0 particle is:

$$\begin{aligned}K_{K^0}&=(\gamma-1)E\\&=(1.783-1)(497.7\,\text{MeV})\\&=388.2\,\text{MeV}\\&=\boxed{388\,\text{MeV}}\end{aligned}$$

The total initial energy in the laboratory frame is:

$$E = 497.7\,\text{MeV} + 388.2\,\text{MeV} = 885.9\,\text{MeV}$$

Express the energy of the other pion:

$$E_\pi = E - 2m_{0\pi}c^2$$

Substitute numerical values and evaluate E_π:

$$E_\pi = 885.9\,\text{MeV} - 2(139.6\,\text{MeV}) = \boxed{607\,\text{MeV}}$$

37 •• [SSM] In reference frame *S'*, two protons, each moving at 0.500*c*, approach each other head-on. (*a*) Calculate the total kinetic energy of the two protons in frame *S*′. (*b*) Calculate the total kinetic energy of the protons as seen in reference frame *S*, which is moving with one of the protons.

Picture the Problem The total kinetic energy of the two protons in Part (*a*) is the sum of their kinetic energies and is given by $K = 2(\gamma - 1)E_0$. Part (*b*) differs from Part (*a*) in that we need to find the speed of the moving proton relative to frame *S*.

(*a*) The total kinetic energy of the protons in frame *S*′ is given by:

$$K = 2(\gamma - 1)E_0$$

Substitute for γ and E_0 and evaluate *K*:

$$K = 2\left(\frac{1}{\sqrt{1 - \frac{(0.500c)^2}{c^2}}} - 1\right)(938.28\,\text{MeV}) = \boxed{290\,\text{MeV}}$$

(*b*) The kinetic energy of the moving proton in frame *S* is given by:

$$K = (\gamma - 1)E_0 \qquad (1)$$

where

$$\gamma = \frac{1}{\sqrt{1 - \frac{uv}{c^2}}}$$

Express the speed *u* of the proton in frame *S*:

$$u = \frac{u_x' + v}{1 + \frac{vu_x'}{c^2}}$$

Substitute numerical values and evaluate *u*:

$$u = \frac{0.500c + 0.500c}{1 + \frac{(0.500c)(0.500c)}{c^2}} = 0.800c$$

Evaluate γ:

$$\gamma = \frac{1}{\sqrt{1-\frac{(0.800c)(0.800c)}{c^2}}} = 1.67$$

Substitute numerical values in equation (1) and evaluate K:

$$K = (1.67-1)(938.28\,\text{MeV}) = \boxed{629\,\text{MeV}}$$

38 •• An antiproton $\overline{\text{p}}$ has the same mass m as a proton p. The antiproton is created during the reaction $\text{p} + \text{p} \to \text{p} + \text{p} + \text{p} + \overline{\text{p}}$. During an experiment, protons at rest in the laboratory are bombarded with protons of kinetic energy K_L, which must be great enough so that an amount of kinetic energy equal to $2mc^2$ can be converted into the rest energy of the two particles. In the frame of the laboratory, the total kinetic energy cannot be converted into rest energy because of conservation of momentum. However, in the zero-momentum reference frame in which the two initial protons are moving toward each other with equal speed u, the total kinetic energy can be converted into rest energy. (*a*) Find the speed of each proton u so that the total kinetic energy in the zero-momentum frame is $2mc^2$. (*b*) Transform to the laboratory's frame in which one proton is at rest, and find the speed u' of the other proton. (*c*) Show that the kinetic energy of the moving proton in the laboratory's frame is $K_\text{L} = 6mc^2$.

Picture the Problem (*a*) We can find the speed of each proton by equating their total relativistic kinetic energy to $2mc^2$. In Part (*b*) we can use the inverse velocity transformation with $V = u$ and $u_x = -u$ to find u_x'. In Part (*c*) we'll need to evaluate γ' for the kinetic energy transformation $K_\text{L} = (\gamma'-1)E_0$.

(*a*) Set the relativistic kinetic energy of the protons equal to $2mc^2$ to obtain:

$$2(\gamma-1)E_0 = 2mc^2 \Rightarrow \gamma = 2$$

Substitute for γ:

$$\frac{1}{\sqrt{1-\frac{u^2}{c^2}}} = 2 \Rightarrow u = \frac{\sqrt{3}}{2}c = \boxed{0.866c}$$

(*b*) Use the inverse velocity transformation with $v = u$ and $u_x = -u$ to find u_x':

$$u_x' = \frac{u_x - v}{1 - \frac{vu_x}{c^2}} = \frac{-\frac{\sqrt{3}}{2}c - \frac{\sqrt{3}}{2}c}{1 - \frac{\left(-\frac{\sqrt{3}}{2}c\right)\left(\frac{\sqrt{3}}{2}\mathrm{c}\right)}{c^2}}$$

$$= \frac{-4\sqrt{3}c}{7} = \boxed{-0.990c}$$

(*c*) The kinetic energy of the moving proton in the laboratory's frame is given by:

$$K_\mathrm{L} = (\gamma' - 1)E_0$$

where

$$\gamma' = \frac{1}{\sqrt{1 - \frac{(u_x')^2}{c^2}}} = \frac{1}{\sqrt{1 - \frac{\left(-\frac{4\sqrt{3}}{7}c\right)^2}{c^2}}} = 7$$

Substitute for γ' and E_0 and evaluate K_L:

$$K_\mathrm{L} = (7-1)mc^2 = \boxed{6mc^2}$$

39 **•••** A particle of mass 1.0 MeV/c^2 and kinetic energy 2.0 MeV collides with a stationary particle of mass 2.0 MeV/c^2. After the collision, the particles stick together. Find (*a*) the speed of the first particle before the collision, (*b*) the total energy of the first particle before the collision, (*c*) the initial total momentum of the system, (*d*) the total kinetic energy after the collision, and (*e*) the mass of the system after the collision.

Picture the Problem Parts (*a*) and (*b*) The initial speed of the particle can be found from its total energy and its total energy found using $E = K + E_0 = \gamma E_0$. (*c*) We can solve $E^2 = p^2c^2 + (mc^2)^2$ for the initial momentum of the system. In Parts (*d*) and (*e*) we can use conservation of energy and conservation of momentum to find the total kinetic energy after the collision and the mass of the system after the collision.

(*a*) Express the total energy of the particle:

$$E = K + E_0 = \gamma E_0$$

Because the kinetic energy of the particle is twice its energy:

$$2E_0 + E_0 = \gamma E_0 \text{ and } \gamma = 3$$

Solving $\gamma = \dfrac{1}{\sqrt{1-(u/c)^2}}$ for u yields:

$$u = c\sqrt{1-\frac{1}{\gamma^2}}$$

Substituting the numerical value of γ and evaluating u gives:

$$u = c\sqrt{1-\frac{1}{3^2}} = c\sqrt{\frac{8}{9}} = \boxed{0.943c}$$

(*b*) The total energy of the particle is:

$$E = K + E_0 = \gamma E_0 = 3E_0$$

Substitute for E_0 and evaluate E:

$$E = 3(1.0\,\text{MeV}) = \boxed{3.0\,\text{MeV}}$$

(*c*) The initial momentum of the incoming particle is related to its energy and mass according to:

$$E^2 = p^2c^2 + \left(mc^2\right)^2$$

Solving for p yields:

$$p = \frac{1}{c}\sqrt{E^2 - \left(mc^2\right)^2}$$

Substitute for E and mc^2 and simplify to obtain:

$$p = \frac{1}{c}\sqrt{(3E_0)^2 - (E_0)^2} = \frac{\sqrt{8}E_0}{c}$$

Substitute for E_0 and evaluate p:

$$p = \frac{\sqrt{8}(1.0\,\text{MeV})}{c} = \boxed{2.8\,\text{MeV}/c}$$

(*d*) and (*e*) From conservation of energy we have:

$$E_\text{f} = E_\text{i} = 5.0\,\text{MeV}$$

From conservation of momentum we have:

$$p_\text{f} = p_\text{i}$$

The final momentum of the system is related to its energy and mass according to:

$$E_\text{f}^2 = p_\text{f}^2c^2 + E_\text{f0}^2 \Rightarrow E_\text{f0} = \sqrt{E_\text{f}^2 - p_\text{f}^2c^2}$$

Substitute numerical values and evaluate E_f0:

$$E_\text{f0} = \sqrt{(5.0\,\text{MeV})^2 - (2.83\,\text{MeV}/c)^2c^2} = 4.12\,\text{MeV}$$

Because $E_\text{f0} = m_\text{f0}c^2$:

$$m_\text{f0} = \frac{E_\text{f0}}{c^2} = \boxed{4.1\,\text{MeV}/c^2}$$

The total kinetic energy after the collision is given by:

$$K_f = E_f - E_{f0} = 5.0\,\text{MeV} - 4.122\,\text{MeV} = \boxed{0.9\,\text{MeV}}$$

General Relativity

40 •• Light traveling in the direction of increasing gravitational potential undergoes a frequency redshift. Calculate the shift in wavelength if a beam of light of wavelength $\lambda = 632.8$ nm is sent up a vertical shaft of height $L = 100$ m.

Picture the Problem Let m represent the mass equivalent of a photon. We can equate the change in the gravitational potential energy of a photon as it rises a distance L in the gravitational field to $h\Delta f$ and then express the wavelength shift in terms of the frequency shift.

The speed of the photons in the light beam are related to their frequency and wavelength:

$$c = f\lambda \Rightarrow f = \frac{c}{\lambda}$$

Differentiate this expression with respect to λ to obtain:

$$\frac{df}{d\lambda} = -c\lambda^{-2} = -\frac{c}{\lambda^2}$$

Approximate $df/d\lambda$ by $\Delta f/\Delta\lambda$ and solve for Δf:

$$\Delta f = -\frac{c}{\lambda^2}\Delta\lambda$$

Divide both sides of this equation by f to obtain:

$$\frac{\Delta f}{f} = \frac{-\dfrac{c}{\lambda^2}\Delta\lambda}{\dfrac{c}{\lambda}} = -\frac{\Delta\lambda}{\lambda}$$

Solving for $\Delta\lambda$ gives:

$$\Delta\lambda = -\lambda\frac{\Delta f}{f} \qquad (1)$$

The change in the energy of the photon as it rises a distance L in a gravitational field is given by:

$$\Delta E = \Delta U = mgL$$

Because $\Delta E = h\Delta f$:

$$h\Delta f = mgL \qquad (2)$$

Letting m represent the mass equivalent of the photon:

$$E = mc^2 = hf \qquad (3)$$

Divide equation (2) by equation (3) to obtain:

$$\frac{h\Delta f}{hf}=\frac{mgL}{mc^2}\Rightarrow\frac{\Delta f}{f}=\frac{gL}{c^2}$$

Substitute for $\Delta f/f$ in equation (1):

$$\Delta\lambda=-\frac{gL\lambda}{c^2}$$

Substitute numerical values and evaluate $\Delta\lambda$:

$$\Delta\lambda=-\frac{(9.81\,\text{m/s}^2)(100\,\text{m})(632.8\,\text{nm})}{(2.998\times10^8\,\text{m/s})^2}=\boxed{-6.90\times10^{-12}\,\text{nm}}$$

41 •• Let us revisit a problem from Chapter 3: Two cannons are pointed directly toward each other, as shown in Figure 39-17. When fired, the cannonballs will follow the trajectories shown. Point *P* is the point where the trajectories cross each other. Ignore any effects due to air resistance. Using the principle of equivalence, show that if the cannons are fired simultaneously (in the rest frame of the cannons), the cannonballs will hit each other at point *P*.

Picture the Problem In a freely falling reference frame, both cannonballs travel along straight lines, so they must hit each other, as they were pointed at each other when they were fired. On the other hand, in Earth's homogeneous gravitational field both balls will have the same vertical acceleration and so will hit each other at *P*. This shows that a homogeneous gravitational field is completely equivalent to a uniformly accelerated reference frame.

42 ••• A horizontal turntable rotates with angular speed ω. There is a clock at the center of the turntable and an identical clock mounted on a turntable a distance r from the center. In an inertial reference frame in which the clock at the center is at rest, the clock at distance r is moving with speed $u = r\omega$. (*a*) Show that from time dilation according to special relativity, the time between ticks, Δt_0 for the clock at rest and Δt_R for the moving clock, are related by

$$\frac{\Delta t_r-\Delta t_0}{\Delta t_0}=-\frac{r^2\omega^2}{2c^2}\qquad r\omega = c$$

(*b*) In a reference frame rotating with the table, both clocks are at rest. Show that the clock at distance r experiences a pseudoforce $F_r = mr\omega^2$ in this rotating frame and that this is equivalent to a difference in gravitational potential between r and the origin of $\phi_r-\phi_0=-\frac{1}{2}r^2\omega^2$. Use the difference in gravitational potential given in Part (*b*) to show that in this frame the difference in time intervals is the same as in the inertial frame.

Picture the Problem Consider the turntable to be a giant hollow cylinder in space that is spinning about its axis. Someone on the inside surface of the cylinder would experience a centripetal acceleration caused by the normal force of the surface pushing them toward the rotation axis. Alternatively, they can consider

that they are not accelerating but a gravitational field $\vec{\boldsymbol{g}} = \omega^2 r\hat{\boldsymbol{r}}$ is pushing them away from the axis ($\hat{\boldsymbol{r}}$ is away from the axis). This is the principle of equivalence. From this perspective, up is toward the axis and the points closer to the axis are at the higher gravitational potential. (Just like the electric field points in the direction of decreasing electric potential, the gravitational field points in the direction of decreasing gravitational potential.)

(*a*) From the time dilation equation we have:

$$\Delta t_{\mathrm{r}} = \frac{\Delta t_0}{\gamma} \text{ and } \frac{\Delta t_{\mathrm{r}} - \Delta t_0}{\Delta t_0} = \frac{1}{\gamma} - 1$$

Because $r\omega/c << 1$:

$$\frac{1}{\gamma} \approx 1 - \frac{1}{2}\frac{u^2}{c^2} = 1 - \frac{r^2\omega^2}{2c^2}$$

Substitute for $\frac{1}{\gamma}$ and simplify to obtain:

$$\frac{\Delta t_{\mathrm{r}} - \Delta t_0}{\Delta t_0} = 1 - \frac{r^2\omega^2}{2c^2} - 1 = \boxed{-\frac{r^2\omega^2}{2c^2}}$$

(*b*) The pseudoforce is given by:

$$F_{\mathrm{P}} = -ma$$

where a is the acceleration of the non-inertial reference frame.

In this case a is the centripetal acceleration:

$$a = -r\omega^2 \Rightarrow F_{\mathrm{P}} = F_r = \boxed{mr\omega^2}$$

To relate this problem to Equation 39-31, point 2 is a distance r from the axis and point 1 is on the axis. The term in parentheses on the right hand side of Equation 39-31 is $\phi_2 - \phi_1$, which translates to $\phi_{\mathrm{r}} - \phi_0$. Because ϕ_{r} is at a lower potential than ϕ_0, this term is negative. Hence:

$$\phi_r - \phi_0 = -\int_0^r \vec{\boldsymbol{g}} \cdot d\vec{\ell} = -\int_0^r \omega^2 r\,\hat{\boldsymbol{r}} \cdot d\vec{\ell} = -\int_0^r \omega^2 r\,dr = \boxed{-\tfrac{1}{2}r^2\omega^2}$$

From Equation 39-31:

$$\frac{\Delta t_{\mathrm{r}} - \Delta t_0}{\Delta t_0} = \frac{1}{c^2}(\phi_r - \phi_0) = \frac{1}{c^2}\left(-\tfrac{1}{2}r^2\omega^2\right)$$

$$= \boxed{-\frac{r^2\omega^2}{2c^2}}$$

General Problems

43 • How fast must a muon travel so that its mean lifetime is 46 μs if its mean lifetime at rest is 2.2 μs?

Picture the Problem We can use the definition of γ and the time dilation equation to find the speed of the muon.

(a) From the definition of γ we have:

$$\gamma = \frac{1}{\sqrt{1-\left(\frac{u}{c}\right)^2}} \Rightarrow \frac{u}{c} = \sqrt{1-\frac{1}{\gamma^2}}$$

Relate the mean lifetime of the muon to its proper lifetime:

$$\Delta t = \gamma \Delta t_p \Rightarrow \gamma = \frac{\Delta t}{\Delta t_p}$$

Substitute in the expression for u/c to obtain:

$$\frac{u}{c} = \sqrt{1-\left(\frac{\Delta t_p}{\Delta t}\right)^2}$$

Substitute numerical values and evaluate u/c:

$$\frac{u}{c} = \sqrt{1-\left(\frac{2.2\ \mu\text{s}}{46\ \mu\text{s}}\right)^2} = 0.999$$

or

$$u = \boxed{0.999c}$$

44 • A distant galaxy is moving away from Earth with a speed that results in each wavelength received on Earth being shifted so that $\lambda' = 2\lambda_0$. Find the speed of the galaxy relative to Earth.

Picture the Problem We can use the relativistic Doppler shift, when the source and the receiver are receding, to relate the frequencies of the two wavelengths and $c = f\lambda$ to express the ratio of the wavelengths as a function of the speed of the galaxy.

When the source and receiver are moving away from each other, the relativistic Doppler shift is given by:

$$f' = \sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}}\,f_0$$

Use the relationship between the wavelength and frequency to obtain:

$$\frac{c}{\lambda'}=\sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}}\frac{c}{\lambda_0}\Rightarrow\frac{\lambda_0}{\lambda'}=\sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}}$$

Because $\lambda' = 2\lambda_0$:

$$\frac{\lambda_0}{2\lambda_0}=\frac{1}{2}=\sqrt{\frac{1-\frac{v}{c}}{1+\frac{v}{c}}}\Rightarrow v=\boxed{0.600c}$$

45 •• **[SSM]** Frames S and S' are moving relative to each other along the x and x' axes (which superpose). Observers at rest in the two frames set their clocks to $t = 0$ when the two origins coincide. In frame S, event 1 occurs at $x_1 = 1.0\ c\cdot\text{y}$ and $t_1 = 1.00$ y and event 2 occurs at $x_2 = 2.0\ c\cdot\text{y}$ and $t_2 = 0.50$ y. These events occur simultaneously in frame S'. (*a*) Find the magnitude and direction of the velocity of S' relative to S. (*b*) At what time do both these events occur as measured in S'?

Picture the Problem We can use Equation 39-12, the inverse time transformation equation, to relate the elapsed times and separations of the events in the two systems to the velocity of S' relative to S. We can use this same relationship in Part (*b*) to find the time at which these events occur as measured in S'.

(*a*) Use Equation 39-12 to obtain:

$$\Delta t' = t_2' - t_1' = \gamma\left[(t_2-t_1)-\frac{v}{c^2}(x_2-x_1)\right]$$
$$=\gamma\left[\Delta t-\frac{v}{c^2}\Delta x\right]$$

Because the events occur simultaneously in frame S', $\Delta t' = 0$ and:

$$0=\Delta t-\frac{v}{c^2}\Delta x\Rightarrow v=\frac{c^2\Delta t}{\Delta x}$$

Substitute for Δt and Δx and evaluate v:

$$v=\frac{c^2(0.50\,\text{y}-1.00\,\text{y})}{2.0\,c\cdot\text{y}-1.00\,c\cdot\text{y}}=\boxed{-0.50c}$$

Because $\Delta t = t_2 - t_1 = -0.50\,\text{y}$:

$$\boxed{S'\text{ moves in the }-x\text{ direction.}}$$

(*b*) Use the inverse time transformation to obtain:

$$t_2' = \gamma\left(t_2 - \frac{vx_2}{c^2}\right) = \frac{t_2 - \dfrac{vx_2}{c^2}}{\sqrt{1-\dfrac{v^2}{c^2}}}$$

Substitute numerical values and evaluate t_2' and t_1':

$$t_2' = t_1' = \frac{0.50\,\text{y} - \dfrac{(-0.50c)(2.0c\cdot\text{y})}{c^2}}{\sqrt{1-\dfrac{(-0.50c)^2}{c^2}}}$$

$$= \boxed{1.7\,\text{y}}$$

46 •• An interstellar spaceship travels from Earth to a star system 12 light-years away (as measured in Earth's frame). The trip takes 15 y as measured by clocks on the spaceship. (*a*) What is the speed of the spaceship relative to Earth? (*b*) When the spaceship arrives, it sends an electromagnetic signal to Earth. How long after the spaceship leaves Earth will observers on Earth receive the signal?

Picture the Problem We can use the relationship between distance, speed, and time and the length contraction relationship to find the speed of the ship relative to Earth. The elapsed time between the departure of the spaceship and the receipt of the signal at Earth is the sum of the travel time to the distant star system and the time it takes the signal to return to Earth.

(*a*) Express the travel time as measured on the spaceship:

$$\Delta t' = \frac{L'}{u} = \frac{L}{\gamma u} \Rightarrow \gamma u = \frac{L}{\Delta t'}$$

Substitute numerical values and evaluate γu:

$$\gamma u = \frac{12c\cdot\text{y}}{15\,\text{y}} = 0.80c$$

or

$$\frac{1}{\sqrt{1-\dfrac{u^2}{c^2}}} = \frac{0.80c}{u} \Rightarrow u = \boxed{0.63c}$$

(*b*) The elapsed time T before Earth receives the signal is the sum of the travel time to the distant star system and the time it takes the signal to return:

$$T = \frac{L}{u} + \frac{L}{c}$$

Substitute numerical values and evaluate T:

$$T = \frac{12c\cdot\text{y}}{0.625c} + \frac{12c\cdot\text{y}}{c} = \boxed{31\,\text{y}}$$

47 •• The neutral pion π^0 has a rest mass of 135.0 MeV/c^2. This particle can be created in a proton–proton collision: p + p $\rightarrow$ p + p + π^0. Determine the threshold kinetic energy for the creation of a π^0 in a collision of a moving and stationary proton. (See Problem 38.)

Picture the Problem We can use conservation of energy to find γ in the CM frame of reference and then use the definition of γ to find the speed u of the projectile proton. We can then use the velocity transformation equation to find the speed and kinetic energy of this proton in the laboratory frame of reference.

Use conservation of energy to find γ in the CM frame of reference:

$$\gamma E_\text{i} = E_\text{f} \Rightarrow \gamma = \frac{E_\text{f}}{E_\text{i}}$$

E_i and E_f are:

$$E_\text{i} = 938\,\text{Mev} + 938\,\text{MeV} = 1876\,\text{MeV}$$

and

$$E_\text{f} = 938\,\text{Mev} + 938\,\text{MeV} + 135.0\,\text{MeV} = 2011\,\text{MeV}$$

Substitute E_i and E_f and evaluate γ:

$$\gamma = \frac{2011\,\text{MeV}}{1876\,\text{MeV}} = 1.072$$

Express γ as a function of the speed u of the projectile proton:

$$\gamma = \frac{1}{\sqrt{1-\frac{u^2}{c^2}}} \Rightarrow u = c\sqrt{1-\frac{1}{\gamma^2}}$$

Substitute for γ and evaluate u:

$$u = c\sqrt{1-\frac{1}{(1.072)^2}} = 0.360c$$

Transform to the laboratory frame and find u':

$$u' = \frac{u-v}{1-\frac{vu}{c^2}} = \frac{0.360c-(-0.360c)}{1-\frac{(0.360c)(-0.360\text{c})}{c^2}} = 0.637c$$

The kinetic energy of the moving proton in the laboratory's frame is given by:

$$K_{\mathrm{L}} = (\gamma_{\mathrm{L}} - 1)E_0$$

where

$$\gamma_{\mathrm{L}} = \frac{1}{\sqrt{1 - \frac{(u')^2}{c^2}}} = \frac{1}{\sqrt{1 - \frac{(0.637c)^2}{c^2}}} = 1.297$$

Substitute for γ_{L} and E_0 and evaluate K_{L}:

$$K_{\mathrm{L}} = (1.297 - 1)(938\,\mathrm{MeV}) = \boxed{281\,\mathrm{MeV}}$$

Remarks: In Problem 51 we show that the threshold kinetic energy of the projectile is given by $K_{\mathrm{th}} = \dfrac{\left(\sum m_{\mathrm{in}} + \sum m_{\mathrm{fin}}\right)\left(\sum m_{\mathrm{fin}} - \sum m_{\mathrm{in}}\right)c^2}{2m_{\mathrm{target}}}$.

48 •• A rocket that has a proper length of 1000 m moves away from a space station and in the $+x$ direction at $0.60c$ relative to an observer on the station. An astronaut stands at the rear of the rocket and fires a dart toward the front of the rocket at $0.80c$ relative to the rocket. How long does it take the dart to reach the front of the rocket (*a*) as measured in the frame of the rocket, (*b*) as measured in the frame of the space station, and (*c*) as measured in the frame of the dart?

Picture the Problem Let S be the frame of the space station and let S′ be the frame of the rocket. Then $v = +0.60c$. In addition, let event A be the dart leaving the gun, event B be the dart arriving at the front of the ship, and L be the rest length of the ship. Then $x'_{\mathrm{A}} = 0$, $x'_{\mathrm{B}} = L$, and $t'_{\mathrm{A}} = 0$. Finally, let u_x and u'_x be the speed of the dart in reference frames S and S′ respectively.

(*a*) In the reference frame of the rocket:

$$t'_{\mathrm{B}} - t'_{\mathrm{A}} = \frac{L}{u'_x} = \frac{L}{0.80c}$$

or, because $t'_{\mathrm{A}} = 0$,

$$t'_{\mathrm{B}} = \frac{L}{0.80c}$$

Substitute numerical values and evaluate t'_{B}:

$$t'_{\mathrm{B}} = \frac{1000\,\mathrm{m}}{(0.80)(2.998\times10^8\ \mathrm{m/s})} = \boxed{4.2\,\mu\mathrm{s}}$$

(*b*) In the reference frame of the space station:

$$t'_B - t'_A = \frac{\dfrac{L}{u'_x} + \dfrac{v(x'_B - x'_B)}{c^2}}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}}$$

or, because $t'_A = 0$, $x'_A = 0$, and $x'_B = L$,

$$t'_B = \frac{\dfrac{L}{u'_x} + \dfrac{vL}{c^2}}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}} = \frac{\left(\dfrac{1}{u'_x} + \dfrac{v}{c^2}\right)L}{\sqrt{1-\left(\dfrac{v}{c}\right)^2}}$$

Substituting numerical values gives:

$$t'_B = \frac{\left(\dfrac{1}{0.80c} + \dfrac{0.60c}{c^2}\right)(1000\text{ m})}{\sqrt{1-\left(\dfrac{0.60c}{c}\right)^2}}$$

$$= \frac{2.313\text{ km}}{c} = \boxed{7.7\,\mu\text{s}}$$

<u>Alternate solution to Part (*b*)</u>

In the reference frame of the dart the speed of the rocket is 0.80c and the length of the ship is:

$$L' = L\sqrt{1 - \frac{(u'_x)^2}{c^2}}$$

or, because $u'_x = 0.80c$,

$$L' = L\sqrt{1 - \frac{(0.80c)^2}{c^2}} = 0.60L$$

The time between events A and B (the proper time) is:

$$t'_B - t'_A = \frac{L'}{u'_x}$$

Substituting for t'_A, L' and u'_x gives:

$$t'_B = \frac{0.60L}{0.80c} = 0.75\frac{L}{c}$$

The speed of the dart in the frame of reference of the space station is given by Equation 39-18*a*:

$$u_x = \frac{u'_x + v}{1 + \dfrac{vu'_x}{c^2}}$$

Substituting numerical values and simplifying yields:

$$u_x = \frac{0.60c + 0.80c}{1 + \dfrac{(0.80c)(0.60c)}{c^2}} = 0.9459c$$

The time between the events in S is related to the proper time between the events by the time dilation formula:

$$t_B - t_A = \frac{t'_B - t'_A}{\sqrt{1-\left(\frac{u_x}{c}\right)^2}}$$

Substituting for L, t_A, t'_B, and u_x gives:

$$t_B = \frac{0.75\frac{(1000\text{ m})}{c}}{\sqrt{1-\left(\frac{0.9459c}{c}\right)^2}} = \frac{2.313\text{ km}}{c}$$

$$= \boxed{7.7\ \mu\text{s}}$$

(*c*) In the bullet's frame of reference, the elapsed time is given by:

$$t'_B - t'_A = \frac{L'}{u'_x}$$

or, because $t'_A = 0$,

$$t'_B = \frac{L'}{u'_x} \qquad (1)$$

The length L' of the rocket in the dart's frame of reference is given by:

$$L' = \frac{L}{\gamma} = L\sqrt{1-\frac{(u'_x)^2}{c^2}}$$

Substitute for L' in equation (1) to obtain:

$$t'_B = \frac{L\sqrt{1-\frac{(u'_x)^2}{c^2}}}{u'_x}$$

Substituting numerical values gives:

$$t'_B = \frac{(1000\text{ m})\sqrt{1-\frac{(0.80c)^2}{c^2}}}{0.80c} = \frac{750\text{ m}}{\text{c}}$$

$$= \boxed{2.5\ \mu\text{s}}$$

49 •• **[SSM]** Using a simple thought experiment, Einstein showed that there is mass associated with electromagnetic radiation. Consider a box of length *L* and mass *M* resting on a frictionless surface. Attached to the left wall of the box is a light source that emits a directed pulse of radiation of energy *E*, which is completely absorbed at the right wall of the box. According to classical electromagnetic theory, this radiation carries momentum of magnitude $p = E/c$ (Equation 32-13). The box recoils when the pulse is emitted by the light source. (*a*) Find the recoil velocity of the box so that momentum is conserved when the light is emitted. (Because *p* is small and *M* is large, you may use classical

mechanics.) (*b*) When the light is absorbed at the right wall of the box the box stops, so the total momentum of the system remains zero. If we neglect the very small velocity of the box, the time it takes for the radiation to travel across the box is $\Delta t = L/c$. Find the distance moved by the box in this time. (*c*) Show that if the center of mass of the system is to remain at the same place, the radiation must carry mass $m = E/c^2$.

Picture the Problem We can use conservation of energy to express the recoil velocity of the box and the relationship between distance, speed, and time to find the distance traveled by the box in time $\Delta t = L/c$. Equating the initial and final locations of the center of mass will allow us to show that the radiation must carry mass $m = E/c^2$.

(*a*) Apply conservation of momentum to obtain:

$$\frac{E}{c} + Mv = p_{\mathrm{i}} = 0 \Rightarrow v = \boxed{-\frac{E}{Mc}}$$

(*b*) The distance traveled by the box in time $\Delta t = L/c$ is:

$$d = v\Delta t = \frac{vL}{c}$$

Substitute for v from (*a*) to obtain:

$$d = \frac{L}{c}\left(-\frac{E}{Mc}\right) = \boxed{-\frac{LE}{Mc^2}}$$

(*c*) Let $x = 0$ be at the center of the box and let the mass of the photon be m. Then initially the center of mass is at:

$$x_{\mathrm{CM}} = \frac{-\frac{1}{2}mL}{M+m}$$

When the photon is absorbed at the other end of the box, the center of mass is at:

$$x_{\mathrm{CM}} = \frac{\left[\frac{-MEL}{Mc^2} + m\left(\frac{1}{2}L - \frac{EL}{Mc^2}\right)\right]}{M+m}$$

Because no external forces act on the system, these expressions for x_{CM} must be equal:

$$\frac{-\frac{1}{2}mL}{M+m} = \frac{\left[\frac{-MEL}{Mc^2} + m\left(\frac{1}{2}L - \frac{EL}{Mc^2}\right)\right]}{M+m}$$

Solving for m yields:

$$m = \frac{E}{c^2\left(1 - \frac{E}{Mc^2}\right)}$$

Because Mc^2 is of the order of 10^{16} J and $E = hf$ is of the order of 1 J for reasonable values of f, $E/Mc^2 << 1$ and:

$$m = \boxed{\frac{E}{c^2}}$$

50 ••• Using the relativistic conservation of momentum and energy and the relation between energy and momentum for a photon $E = pc$, prove that a free electron (an electron not bound to an atomic nucleus) cannot absorb or emit a photon.

Picture the Problem Without loss of generality, we'll consider the absorption case. We'll assume that the electron is initially at rest and that it travels with a speed v after it absorbs the photon. Applying the conservation of energy and the conservation of momentum will lead us to an absurd conclusion that, in turn, will force us to abandon our initial assumption that an electron can absorb a photon. Such an argument is known as a *reductio ad absurdum* argument.

When the electron absorbs a photon, the conservation of relativistic momentum requires that its momentum become:

$$p = \gamma mv$$

From the conservation of energy:

$$mc^2 + pc = \gamma mc^2 \Rightarrow p = (\gamma - 1)mc$$

Equate these expression for p to obtain:

$$\gamma mv = (\gamma - 1)mc \Rightarrow v = \left(\frac{\gamma - 1}{\gamma}\right)c \quad (1)$$

Squaring both sides of the equation gives:

$$v^2 = \left(\frac{\gamma - 1}{\gamma}\right)^2 c^2 = \frac{\gamma^2 - 2\gamma + 1}{\gamma^2}c^2 \quad (2)$$

From the definition of γ:

$$\gamma^2 = \frac{1}{1 - \frac{v^2}{c^2}} = \frac{c^2}{c^2 - v^2}$$

Solve for v^2 to obtain:

$$v^2 = \frac{\gamma^2 - 1}{\gamma^2}c^2$$

Substituting for v^2 in equation (2) and simplifying gives:

$$\frac{\gamma^2 - 1}{\gamma^2}c^2 = \frac{\gamma^2 - 2\gamma + 1}{\gamma^2}c^2$$

or

$$-1 = -2\gamma + 1 \Rightarrow \gamma = 1$$

Substitute for γ in equation (1) and evaluate v:

$$v = \left(\frac{1-1}{1}\right)c = 0$$

Our assumption that an electron can absorb a photon has led to the contradictory conclusion that its speed after the absorption is zero. Hence we must conclude that the electron cannot absorb a photon.

51 ••• [SSM] When a moving particle that has a kinetic energy greater than the threshold kinetic energy K_{th} strikes a stationary target particle, one or more particles may be created in the inelastic collision. Show that the threshold kinetic energy of the moving particle is given by

$$K_{th} = \frac{(\Sigma m_{in} + \Sigma m_{fin})(\Sigma m_{fin} + \Sigma m_{in})c^2}{2m_{target}}$$

Here Σm_{in} is the sum of the masses of the particles prior to the collision, Σm_{fin} is the sum of the masses of the particles following the collision, and m_{target} is the mass of the target particle. Use this expression to determine the threshold kinetic energy of protons incident on a stationary proton target for the production of a proton–antiproton pair; compare your result with the result of Problem 38.

Picture the Problem Let m_i denote the mass of the incident (projectile) particle. Then $\sum m_{in} = m_i + m_{target}$ and we can use this expression to determine the threshold kinetic energy of protons incident on a stationary proton target for the production of a proton–antiproton pair.

Consider the situation in the center of mass reference frame. At threshold we have:

$$E^2 - p^2c^2 = \sum m_{fin}c^2$$

Note that this is a relativistically invariant expression.

In the laboratory frame, the target is at rest so:

$$E_{target} = E_t = E_{t,0}$$

We can, therefore, write:

$$(E_i + E_{t,0})^2 - p_i^2c^2 = \left(\sum m_{fin}c^2\right)^2$$

For the incident particle:

$$E_i^2 - p_i^2c^2 = E_{i,0}^2$$

and

$$E_i = E_{i,0} + K_{th}$$

where K_{th} is the threshold kinetic energy of the incident particle in the laboratory frame.

Express K_{th} in terms of the rest energies:

$$\left(E_{\text{t,0}} + E_{\text{i.0}}\right)^2 + 2K_{\text{th}}E_{\text{t,0}} = \left(\sum m_{\text{fin}}c^2\right)^2$$

where

$$E_{\text{t,0}} + E_{\text{i.0}} = \sum m_{\text{fin}}c^2$$

and

$$E_{\text{t,0}} = m_{\text{target}}c^2$$

Substitute to obtain:

$$\left(\sum m_{\text{fin}}c^2\right)^2 + 2K_{\text{th}}m_{\text{target}}c^2 = \left(\sum m_{\text{fin}}c^2\right)^2$$

Solving for K_{th} gives:

$$K_{\text{th}} = \boxed{\frac{\left(\sum m_{\text{in}} + \sum m_{\text{fin}}\right)\left(\sum m_{\text{fin}} - \sum m_{\text{in}}\right)c^2}{2m_{\text{target}}}}$$

For the creation of a proton-antiproton pair in a proton-proton collision:

$$\sum m_{\text{in}} = 2m_{\text{p}}\ ,\ \sum m_{\text{fin}} = 4m_{\text{p}} \text{ and } m_{\text{target}} = m_{\text{p}}$$

Substituting for the sums and simplifying yields:

$$K_{\text{th}} = \frac{\left(2m_{\text{p}} + 4m_{\text{p}}\right)\left(4m_{\text{p}} - 2m_{\text{p}}\right)c^2}{2m_{\text{p}}} = \frac{\left(6m_{\text{p}}\right)\left(2m_{\text{p}}\right)c^2}{2m_{\text{p}}} = \boxed{6m_{\text{p}}c^2}$$

in agreement with Problem 38.

52 ••• A particle of mass *M* decays into two identical particles, each of mass *m*, where *m* = 0.30*M*. Prior to the decay, the particle of mass *M* has a total energy of $4.0Mc^2$ in the laboratory reference frame. The velocities of the decay products are along the direction of motion of *M*. Find the velocities of the decay products in the laboratory reference frame.

Picture the Problem We'll solve the problem for the general case of a particle of rest mass *M* decaying into two identical particles each of rest mass *m*.

In the center of mass reference frame:

$$Mc^2 = 2mc^2 = 2\gamma mc^2$$

Solve for *u*/*c* to obtain:

$$\frac{u}{c} = \sqrt{1 - \left(\frac{2m}{M}\right)^2}$$

where *u* is the speed of each of the decay particles in the CM frame.

Next we determine the speed v of the laboratory frame relative to the CM frame. The energy of the particle of rest mass M is:

$$\gamma_{\mathrm{CM}}Mc^2 \text{ where } \gamma_{\mathrm{CM}} = \frac{1}{\sqrt{1-\frac{v^2}{c^2}}}$$

$$\text{and } \frac{v}{c} = \beta_{\mathrm{CM}} = \sqrt{1-\frac{1}{\gamma_{\mathrm{CM}}^2}}$$

Use Equation 39-18a to express u_{lab}, the speeds of the decay products in the laboratory reference frame:

$$u_{\mathrm{lab}} = \frac{\beta_{\mathrm{CM}} \pm \frac{u}{c}}{1 \pm \beta_{\mathrm{CM}}\frac{u}{c}}c$$

where ± refers to the fact that one of the decay particles will travel in the direction of M, and the other in the direction opposite to that of M.

In this problem we have:

$$\gamma_{\mathrm{CM}} = 4.0\,,\ \beta_{\mathrm{CM}} = 0.968\,,\ \frac{2m_0}{M_0} = 0.600\,,$$

$$\text{and } \frac{u}{c} = 0.800$$

Substituting numerical values gives:

$$u_{\mathrm{lab}} = \frac{0.968 + 0.800}{1+(0.968)(0.800)}c = \boxed{0.996c}$$

and

$$u_{\mathrm{lab}} = \frac{0.968 - 0.800}{1-(0.968)(0.800)}c = \boxed{0.745c}$$

53 ••• A rod of proper length L_{p} makes an angle θ with the x axis in frame S. Show that the angle θ' made with the x' axis in frame S', which is moving in the $+x$ direction with speed v, is given by $\tan\theta' = \gamma\tan\theta$ and that the length of the stick in S' is $L' = L_{\mathrm{p}}\left(\gamma^{-2}\cos^2\theta + \sin^2\theta\right)^{1/2}$.

Picture the Problem We can write the components of the stick in its reference frame and then apply the Lorentz length contraction equation to obtain the given result.

In its reference frame, the stick has x and y components:

$$L_{\mathrm{p}x} = L_{\mathrm{p}}\cos\theta \text{ and } L_{\mathrm{p}y} = L_{\mathrm{p}}\sin\theta$$

Only $L_{\mathrm{p}x}$ is Lorentz contracted:

$$L_x' = \frac{L_{\mathrm{p}x}}{\gamma}$$

Hence, the length in the reference frame S' is:

$$L' = \left[(L_x')^2 + (L_y')^2\right]^{1/2} = \boxed{L_\mathrm{p}\left(\frac{\cos^2\theta}{\gamma^2} + \sin^2\theta\right)^{1/2}}$$

The angle that L' makes with the x' axis is given by:

$$\tan\theta' = \frac{L_y'}{L_x'} = \frac{\sin\theta}{\dfrac{\cos\theta}{\gamma}} = \boxed{\gamma\tan\theta}$$

54 ••• Show that if a particle moves at an angle θ with the x axis with speed u in frame S, it moves at an angle θ' with the x' axis in S' given by

$$\tan\theta' = \gamma^{-1}\sin\theta/(\cos\theta - v/u)$$

Picture the Problem We can express the tangent of the angle u' makes with the x' axis and then use the velocity transformation equations to obtain the given result.

Express the tangent of the angle u' makes with the x' axis:

$$\tan\theta' = \frac{u_y'}{u_x'}$$

Substitute for u_y' and u_x':

$$\tan\theta' = \frac{\dfrac{u_y}{\gamma\left(1 - \dfrac{vu_x}{c^2}\right)}}{\dfrac{u_x - v}{1 - \dfrac{vu_x}{c^2}}} = \frac{u_y}{\gamma(u_x - v)}$$

Substitute for u_y and u_x and simplify to obtain:

$$\tan\theta' = \frac{u\sin\theta}{\gamma(u\cos\theta - v)} = \boxed{\frac{\gamma^{-1}\sin\theta}{\cos\theta - v/u}}$$

55 ••• **[SSM]** For the special case of a particle moving with speed u along the y axis in frame S, show that its momentum and energy in frame S' are related to its momentum and energy in S by the transformation equations

$$p_x' = \gamma\left(p_x - \frac{vE}{c^2}\right) \qquad p_y' = p_y \qquad p_z' = p_z \qquad \frac{E'}{c} = \gamma\left(\frac{E}{c} - \frac{vp_x}{c}\right).$$

Compare these equations with the Lorentz transformation equations for x', y', z', and t'. Notice that that the quantities p_x, p_y, p_z and E/c transform in the same way as do x, y, z, and ct.

Picture the Problem We can use the expressions for $\vec{p}$ and E in S together with the relations we wish to verify and the inverse velocity transformation equations to establish the condition $u'^2 = (u_x')^2 + (u_y')^2 + (u_z')^2 = v^2 + \frac{u^2}{\gamma^2}$ and then use this result to verify the given expressions for p_x', p_y', p_z' and E'/c.

In any inertial frame the momentum and energy are given by:

$$\vec{p} = \frac{m\vec{u}}{\sqrt{1-\frac{u^2}{c^2}}} \text{ and } E = \frac{mc^2}{\sqrt{1-\frac{u^2}{c^2}}}$$

where $\vec{u}$ is the velocity of the particle and u is its speed.

The components of $\vec{p}$ in S are:

$$p_x = \frac{mu_x}{\sqrt{1-\frac{u^2}{c^2}}},\ p_y = \frac{mu_y}{\sqrt{1-\frac{u^2}{c^2}}}, \text{ and}$$

$$p_z = \frac{mu_z}{\sqrt{1-\frac{u^2}{c^2}}}$$

Because $u_x = u_z = 0$ and $u_y = u$:

$$p_x = p_z = 0 \text{ and } p_y = \frac{mu}{\sqrt{1-\frac{u^2}{c^2}}}$$

Substituting zeros for p_x and p_z in the relations we are trying to show yields:

$$p_x' = \gamma\left(0 - \frac{vE}{c^2}\right) = -\gamma\frac{vE}{c^2},\ p_y' = p_y,$$

$p_z' = 0$, and

$$\frac{E'}{c} = \gamma\left(\frac{E}{c} - 0\right) = \gamma\frac{E}{c}$$

In S' the momentum components are:

$$p_x' = \frac{mu_x'}{\sqrt{1-\frac{u'^2}{c^2}}},\ p_y' = \frac{mu_y'}{\sqrt{1-\frac{u'^2}{c^2}}}, \text{ and}$$

$$p_z' = \frac{mu_z'}{\sqrt{1-\frac{u'^2}{c^2}}}$$

The inverse velocity transformations are:

$$u_x' = \frac{u_x - v}{\sqrt{1-\frac{vu_x}{c^2}}},\ u_y' = \frac{u_y}{\sqrt{1-\frac{vu_y}{c^2}}},\ \text{and}$$

$$u_z' = \frac{u_z}{\sqrt{1-\frac{vu_z}{c^2}}}$$

Substitute $u_x = u_z = 0$ and $u_y = u$ to obtain:

$$u_x' = -v,\ u_y' = \gamma u,\ \text{and}\ u_z' = 0$$

Thus:

$$u'^2 = (u_x')^2 + (u_y')^2 + (u_z')^2$$
$$= v^2 + \frac{u^2}{\gamma^2}$$

First, we verify that $p_z' = p_z = 0$:

$$p_z' = \frac{m(0)}{\sqrt{1-\frac{u'^2}{c^2}}} = p_z = \boxed{0}$$

Next, we verify that $p_y' = p_y$:

$$p_y' = \frac{mu_y'}{\sqrt{1-\frac{u'^2}{c^2}}} = \frac{mu}{\gamma\sqrt{1-\frac{v^2}{c^2}-\frac{u^2}{\gamma^2c^2}}} = \frac{mu}{\sqrt{1-\frac{u^2}{c^2}}}\frac{\sqrt{1-\frac{u^2}{c^2}}}{\gamma\sqrt{1-\frac{v^2}{c^2}-\frac{u^2}{\gamma^2c^2}}}$$
$$= \frac{mu}{\sqrt{1-\frac{u^2}{c^2}}}\sqrt{\frac{\left(1-\frac{u^2}{c^2}\right)\left(1-\frac{v^2}{c^2}\right)}{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}} = p_y\sqrt{\frac{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}}$$
$$= \boxed{p_y}$$

Next, we verify that $p_x' = \gamma\left(p_x - \frac{vE}{c^2}\right)$:

$$p_x' = \frac{mu_x'}{\sqrt{1-\frac{u'^2}{c^2}}} = \frac{-mv}{\gamma\sqrt{1-\frac{v^2}{c^2}-\frac{u^2}{\gamma^2c^2}}} = -\frac{\gamma v}{c^2}\frac{mc^2}{\sqrt{1-\frac{u^2}{c^2}}}\frac{\gamma^{-1}\sqrt{1-\frac{u^2}{c^2}}}{\sqrt{1-\frac{v^2}{c^2}-\frac{u^2}{\gamma^2c^2}}}$$

$$= -\frac{\gamma v}{c^2}E\sqrt{\frac{\left(1-\frac{u^2}{c^2}\right)\left(1-\frac{v^2}{c^2}\right)}{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}} = -\frac{\gamma v}{c^2}E\sqrt{\frac{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}}$$

$$= \boxed{-\frac{\gamma v}{c^2}E}$$

Finally, we verify that $\frac{E'}{c} = \gamma\left(\frac{E}{c} - \frac{vp_x}{c}\right) = \gamma\frac{E}{c}$, or $E' = \gamma E$:

$$E' = \frac{mc^2}{\sqrt{1-\frac{u'^2}{c^2}}} = \frac{\gamma mc^2}{\sqrt{1-\frac{u^2}{c^2}}}\frac{\gamma^{-1}\sqrt{1-\frac{u^2}{c^2}}}{\sqrt{1-\frac{u'^2}{c^2}}} = \gamma E\frac{\gamma^{-1}\sqrt{1-\frac{u^2}{c^2}}}{\sqrt{1-\frac{v^2}{c^2}-\frac{u^2}{\gamma^2c^2}}}$$

$$= \gamma E\sqrt{\frac{\left(1-\frac{u^2}{c^2}\right)\left(1-\frac{v^2}{c^2}\right)}{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}} = \gamma E\sqrt{\frac{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}{1-\frac{v^2}{c^2}-\frac{u^2}{c^2}\left(1-\frac{v^2}{c^2}\right)}}$$

$$= \boxed{\gamma E}$$

The *x, y, z,* and *t* transformation equations are:

$x' = \gamma(x - vt)$, $y' = y$, $z' = z$
and
$t' = \gamma\left(t - \frac{vx}{c^2}\right)$

The $x, y, z,$ and ct transformation equations are:

$$x' = \gamma\left(x - \frac{v}{c}ct\right),\ y' = y,\ z' = z$$

and

$$ct' = \gamma\left(ct - \frac{v}{c}x\right)$$

The $p_x, p_y, p_z,$ and E/c transformation equations are:

$$p_x' = \gamma\left(p_x - \frac{v}{c}\frac{E}{c}\right),\ p_y' = p_y,\ p_z' = p_z$$

and

$$\frac{E'}{c} = \gamma\left(\frac{E}{c} - \frac{v}{c}p_x\right)$$

Note that the transformation equations for $x, y, z,$ and ct and the transformation equations for $p_x, p_y, p_z,$ and E/c are identical.

56 ••• The equation for the spherical wavefront of a light pulse that begins at the origin at time $t = 0$ is $x^2 + y^2 + z^2 - (ct)^2 = 0$. Frame S' moves with velocity v along the x axis. Using the Lorentz transformation, show that such a light pulse also has a spherical wavefront in frame S' by showing that $x'^2 + y'^2 + z'^2 - (ct')^2 = 0$.

Picture the Problem The Lorentz transformation was derived on the basis of the postulate that the speed of light is c in any inertial reference frame. Thus, if the clocks in S and S' are synchronized at $t = t' = 0$, then it follows from the Einstein postulate that $r^2 = c^2t^2$ and $r'^2 = c^2t'^2$ or $r^2 - c^2t^2 = 0 = r'^2 - c^2t'^2$. In other words, the quantity $s^2 = r^2 - c^2t^2 = 0$ is a relativistic invariant, which can also be written as $x^2 + y^2 + z^2 - c^2t^2 = 0$.

Using the Lorentz transformation equations for x, y, z, and t we have:

$$x'^2 + y'^2 + z'^2 - (ct')^2 = \gamma^2(x^2 - 2vxt + v^2t^2) + y^2 + z^2 - \gamma^2(c^2t^2 - 2vxt + v^2x^2/c^2)$$

The terms linear in x cancel and the terms in x^2 combine to give:

$$\gamma^2x^2(1 - v^2/c^2) = x^2$$

The coefficients of the terms in $(ct)^2$ give:

$$\gamma^2(v^2/c^2 - 1) = -1$$

Thus, $r^2 - c^2t^2 = r'^2 - c^2t'^2$ as required by the Einstein postulate.

57 ••• In Problem 56, you showed that the quantity $x^2 + y^2 + z^2 - (ct)^2$ has the same value (0) in both S and S'. A quantity that has the same value in all inertial frames is called a *Lorentz invariant*. From the results of Problem 55, the quantity $p_x^2 + p_y^2 + p_z^2 - E^2/c^2$ must also be a Lorentz invariant. Show that this quantity has the value $-m^2c^2$ in both the S and S' reference frames.

Picture the Problem We'll use Equation 39-27 to show that this quantity has the value $-mc^2$ in both the S and S' reference frames.

From Equation 39-27, the relationship between total energy E, momentum p, and rest energy mc^2 is:

$$E^2 = p^2c^2 + \left(mc^2\right)^2$$

or

$$p^2c^2 - E^2 = -\left(mc^2\right)^2$$

Divide both sides of this equation by c^2 to obtain:

$$p^2 - \left(\frac{E}{c}\right)^2 = -(mc)^2 \qquad (1)$$

We can relate p to p_x, p_y, and p_z:

$$p^2 = p_x^2 + p_y^2 + p_z^2$$

Substitute for p^2 in equation (1) to obtain:

$$p_x^2 + p_y^2 + p_z^2 - \left(\frac{E}{c}\right)^2 = -m^2c^2$$

Because m is the mass of the particle in its rest frame, it is constant. Hence:

$p^2 - \left(\dfrac{E}{c}\right)^2$ must be a relativistic invariant.

Also, in Problem 55 we saw that the components of p and the quantity E/c transform like the components of r and the quantity ct. In Problem 56 we demonstrated that $r^2 - (ct)^2$ is a relativistic invariant. Consequently, $p^2 - (E/c)^2$ must also be relativistically invariant.

58 ••• A long rod that is parallel to the x axis is released from rest. Subsequently, it is in free fall with an acceleration of magnitude g in the $-y$ direction. An observer in a rocket ship moving with speed v parallel to the x axis passes by. Using the Lorentz transformations, show that the observer on the rocket ship will measure the rod to be bent into a parabolic shape. Is the parabola concave upward or concave downward?

Picture the Problem We can use the inverse Lorentz transformation for time to show that the observer will conclude that the rod is bent into a parabolic shape.

In frame S where the rod is not moving along the x axis, the height of the rod at time t is:

$$y(t) = -\tfrac{1}{2}gt^2$$

The inverse Lorentz time transformation is:

$$t = \gamma\left(t' + \frac{vx}{c^2}\right)$$

Express $y'(t)$ in the moving frame of reference:

$$y'(t) = -\tfrac{1}{2}g\gamma\left(t' + \frac{vx}{c^2}\right)^2$$

Evaluate $y'(t)$ at $t' = 0$ to obtain:

$$y'(t) = -\frac{g\gamma v^2}{2c^2}x^2$$

Because $y'(t) = -\frac{g\gamma v^2}{2c^2}x^2$ is the equation of a parabola, we've shown that the moving observer will conclude that the rod is bent into a parabolic shape. Because the coefficient of x^2 is negative, the parabola is concave downward.

59 •• Show that if u_x' and v in Equation 39-18*a* are both less than c, then u_x is less than c. (*Hint*: Let $u_x' = (1-\varepsilon_1)c$ and $v = (1-\varepsilon_2)c$, where ε_1 and ε_2 are small positive numbers that are less than 1.)

Picture the Problem We can make the substitutions given in the hint in Equation 39-18*a* and simplify the resulting expression to show that $u_x < c$.

Equation 39-18*a* gives the x direction relativistic velocity transformation:

$$u_x = \frac{u_x' + v}{1 + \frac{vu_x'}{c^2}} \quad \text{or} \quad \frac{u_x}{c} = \frac{u_x' + v}{c + \frac{vu_x'}{c}}$$

Make the substitutions given in the hint to obtain:

$$\frac{u_x}{c} = \frac{(1-\varepsilon_1)c + (1-\varepsilon_2)c}{c + \frac{(1-\varepsilon_2)c(1-\varepsilon_1)c}{c}}$$
$$= \frac{2-(\varepsilon_1+\varepsilon_2)}{1+(1-\varepsilon_2)(1-\varepsilon_1)}$$
$$= \frac{2-(\varepsilon_1+\varepsilon_2)}{2-(\varepsilon_1+\varepsilon_2)+\varepsilon_1\varepsilon_2}$$

Because ε_1 and ε_2 are small positive numbers that are less than 1, the numerator is less than the denominator and:

$$\frac{u_x}{c} < 1 \Rightarrow u_x < \boxed{c}$$

60 ••• In reference frame S the acceleration of a particle is $\vec{a} = a_x\hat{\boldsymbol{i}} + a_y\hat{\boldsymbol{j}} + a_z\hat{\boldsymbol{k}}$. Derive expressions for the acceleration components a_x', a_y', and a_z' of the particle in reference frame S' that is moving relative to S in the x direction with velocity v.

Picture the Problem We can evaluate the differentials of Equations 39-19*a, b,* and c and 39-12 and express their ratio to obtain expressions for a_x', a_y', and a_z'.

From Equation 39-19*a* we have:

$$du_x' = d\left(\frac{u_x - v}{1 - \frac{vu_x}{c^2}}\right) = \frac{\left(1 - \frac{vu_x}{c^2}\right)du_x + (u_x - v)\left(\frac{v}{c^2}\right)du_x}{\left(1 - \frac{vu_x}{c^2}\right)^2} = \frac{\left(1 - \frac{v^2}{c^2}\right)}{\left(1 - \frac{vu_x}{c^2}\right)^2}du_x$$

From Equation 39-12:

$$dt' = \gamma d\left(t - \frac{vx}{c^2}\right) = \gamma dt - \frac{\gamma v}{c^2}dx = \frac{\gamma v}{c^2}\frac{dx}{dt}dt = \gamma\left(1 - \frac{vu_x}{c^2}\right)dt$$

Divide du_x' by dt' to obtain:

$$a_x' = \frac{du_x'}{dt'} = \frac{\frac{\left(1 - \frac{v^2}{c^2}\right)}{\left(1 - \frac{vu_x}{c^2}\right)^2}du_x}{\gamma\left(1 - \frac{vu_x}{c^2}\right)dt} = \frac{\left(1 - \frac{v^2}{c^2}\right)}{\gamma\left(1 - \frac{vu_x}{c^2}\right)^3}\frac{du_x}{dt} = \boxed{\frac{1}{\gamma^3\delta^3}a_x} \text{ where } \delta = 1 - \frac{vu_x}{c^2}$$

Proceeding in exactly the same manner, one obtains:

$$a_y' = \boxed{\frac{1}{\gamma^2\delta^2}a_y + \frac{vu_y}{\gamma^3\delta^3c^2}a_x}$$

and an identical expression for a_z' with z replacing y.

Chapter 40
Nuclear Physics

Conceptual Problems

1 • Isotopes of nitrogen, iron and tin have stable isotopes ^{14}N, ^{56}Fe and ^{118}Sn. Give the symbols for two other isotopes of (*a*) nitrogen, (*b*) iron, and (*c*) tin.

Determine the Concept Two or more nuclides with the same atomic number Z but different *N* and *A* numbers are called isotopes.

(*a*) Two other isotopes of ^{14}N are: ^{15}N, ^{16}N

(*b*) Two other isotopes of ^{56}Fe are: ^{54}Fe, ^{55}Fe

(*c*) Two other isotopes of ^{118}Sn are: ^{117}Sn, ^{119}Sn

2 • Why is the decay chain $A = 4n + 1$ not found in nature?

Determine the Concept The parent of that series, ^{237}Np, the longest-lived member of this decay series, has a half-life of 2×10^6 y that is much shorter than the age of Earth. There is no naturally occurring Np remaining on Earth.

3 • A decay by α emission is often followed by β decay. When this occurs, it is by β^- and not β^+ decay. Why?

Determine the Concept Generally, β-decay leaves the daughter nucleus neutron rich, i.e., above the line of stability. The daughter nucleus therefore tends to decay via β^- emission which converts a nuclear neutron to a proton.

4 • The half-life of ^{14}C is much less than the age of the universe, yet ^{14}C is found in nature. Why?

Determine the Concept ^{14}C is found on Earth because it is constantly being formed by cosmic rays in the upper atmosphere in the reaction $^{14}N + n \rightarrow {}^{14}C + {}^{1}H$.

5 • What effect would a long-term variation in cosmic-ray activity have on the accuracy of ^{14}C dating?

Determine the Concept It would make the dating unreliable because the current concentration of ^{14}C is not equal to that at some earlier time.

6 • Why does an element that has $Z = 130$ not exist?

Determine the Concept An element with such a high Z value (the Coulomb-repulsion force is proportional to Z^2) would either fission spontaneously or decay almost immediately by α emission (see Figure 40-3).

7 • Why is a moderator needed in an ordinary nuclear fission reactor?

Determine the Concept The probability for neutron capture by the fissionable nucleus is large only for slow (thermal) neutrons. The neutrons emitted in the fission process are fast (high energy) neutrons and must be slowed to thermal neutrons before they are likely to be captured by another fissionable nucleus.

8 • Explain why water is more effective than lead in slowing down fast neutrons.

Determine the Concept The process of ″slowing down″ involves the sharing of energy of a fast neutron and another nucleus in an elastic collision. The fast particle will lose maximum energy in such a collision if the target particle is of the same mass as the incident particle. Hence, neutron-proton collisions are most effective in slowing down neutrons. However, ordinary water cannot be used as a moderator because protons will capture the slow neutrons and form deuterons.

9 • The stable isotope of sodium is ^{23}Na. What kind of beta decay would you expect of (*a*) ^{22}Na and (*b*) ^{24}Na?

Determine the Concept Beta decay occurs in nuclei that have too many or too few neutrons for stability. In β decay, A remains the same while Z either increases by 1 (β^- decay) or decreases by 1 (β^+ decay).

(*a*) The reaction is:

$$^{22}_{11}\text{Na} \to {}^{22}_{10}\text{Ne} + {}^{0}_{+1}\beta \Rightarrow \boxed{\beta^+}\ \text{decay}$$

(*b*) The reaction is:

$$^{24}_{11}\text{Na} \to {}^{24}_{12}\text{Mg} + {}^{0}_{-1}\beta \Rightarrow \boxed{\beta^-}\ \text{decay}$$

10 • What is the advantage of a breeder reactor over an ordinary reactor? What are the disadvantages of a breeder reactor?

Advantages	Disadvantages
The reactor uses ^{238}U, which, by neutron capture and subsequent decays, produces ^{239}Pu. Thus plutonium isotope fissions by fast neutron capture. Thus, the breeder reactor uses the plentiful uranium isotope and does not need a moderator to slow the neutrons needed for fission.	The fraction of delayed neutrons emitted in the fission of ^{239}Pu is very small. Consequently, control of the fission reaction is very difficult, and the safety hazards are more severe than for the ordinary reactor that uses ^{235}U as fuel.

11 • True or false:

(*a*) In a breeder reactor, fuel can be produced as fast as it is consumed.
(*b*) The atomic nucleus is composed of protons, neutrons, and electrons.
(*c*) The mass of a ^{2}H nucleus is less than the mass of a ^{1}H nucleus plus the mass of a neutron.
(*d*) After two half-lives, all the radioactive nuclei in a given sample have decayed.

(*a*) True (given an unlimited supply of ^{238}U).

(*b*) False. The nucleus does not contain electrons.

(*c*) True.

(*d*) False. After two half-lives, three-fourths of the radioactive nuclei in a given sample have decayed.

12 • Why is it that extreme changes in the temperature or the pressure of a radioactive sample have little or no effect on the radioactivity?

Determine the Concept Exponential time dependence is characteristic of all radioactivity and indicates that radioactive decay is a statistical process. Because each nucleus is well shielded from others by the atomic electrons, pressure and temperature changes have little or no effect on the rate of radioactive decay or other nuclear properties.

Estimation and Approximation

13 • We found in Chapter 25 that the ratio of the resistivity of the most insulating material to the resistivity of the least resistive material (excluding superconductors) is approximately 10^{22}. Few properties of materials show such a wide range of values. Using information in the textbook or other resources, find the ratio of largest to smallest for some nuclear properties of matter. Some examples might be the range of mass densities found in an atom, the half-life of radioactive nuclei, or the range of nuclear masses.

Picture the Problem There is no table of half lives in the text although the information is mentioned in the alpha particle discussion for alpha decay (about 15 orders of magnitude). Mass density in an atom ranges roughly as the cube of the radius of an atom to that of the nucleus, also about 15 orders of magnitude. Nuclear masses only range 2 orders of magnitude.

Material property	Ratio (order of magnitude)
Mass density	10^{15}
Half life	10^{15}
Nuclear masses	2

14 •• According to the United States Department of Energy, the U.S. population consumes approximately 10^{20} joules of energy each year. Estimate the mass (in kilograms) of (*a*) uranium that would be needed to produce this much energy using nuclear fission and (*b*) deuterium and tritium that would be needed to produce this much energy using nuclear fusion.

Picture the Problem The mass of ^{235}U required is given by $m_{235} = (N/N_A)M_{235}$, where M_{235} is the molecular mass of ^{235}U and N is the number of fissions required to produce 10^{20} J. The mass of deuterium and tritium required can be found similarly.

(*a*) Relate the mass of ^{235}U required to the number of fissions N required:

$$m_{235} = \frac{N}{N_A} M_{235}$$

where M_{235} is the molecular mass of ^{235}U.

Because $N = \dfrac{E_{\text{annual}}}{E_{\text{per fission}}}$:

$$m_{235} = \frac{E_{\text{annual}} M_{235}}{N_A E_{\text{per fission}}}$$

Substitute numerical values and evaluate m_{235}:

$$m_{235} = \frac{(1\times10^{20}\ \text{J})(235\,\text{g/mol})}{\left(6.022\times10^{23}\,\frac{\text{nuclei}}{\text{mol}}\right)\left(200\,\text{MeV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)} \approx \boxed{5\times10^{6}\ \text{kg}}$$

(*b*) Relate the mass of ^{2}H and ^{3}H required to the number of fusions N required:

$$m_{^2\text{H}+^3\text{H}} = \frac{N}{N_\text{A}} M_{^2\text{H}+^3\text{H}}$$

where $M_{^2\text{H}+^3\text{H}}$ is the molecular mass of ^{2}H + ^{3}H.

Because $N = \dfrac{E_\text{annual}}{E_\text{per fission}}$:

$$m_{^2\text{H}+^3\text{H}} = \frac{E_\text{annual} M_{^2\text{H}+^3\text{H}}}{N_\text{A} E_\text{per fission}}$$

Substitute numerical values and evaluate $m_{^2\text{H}+^3\text{H}}$:

$$m_{^2\text{H}+^3\text{H}} = \frac{(1\times10^{20}\ \text{J})(5\,\text{g/mol})}{\left(6.022\times10^{23}\,\frac{\text{nuclei}}{\text{mol}}\right)\left(18\,\text{MeV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}\right)} \approx \boxed{3\times10^{6}\ \text{kg}}$$

Properties of Nuclei

15 • [SSM] Calculate the binding energy and the binding energy per nucleon from the masses given in Table 40-1 for (*a*) ^{12}C, (*b*) ^{56}Fe, and (*c*) ^{238}U.

Picture the Problem To find the binding energy of a nucleus we add the mass of its neutrons to the mass of its protons and then subtract the mass of the nucleus and multiply by c^2. The binding energy per nucleon is the ratio of the binding energy to the mass number of the nucleus.

(*a*) For ^{12}C, Z = 6 and N = 6. Add the mass of the neutrons to that of the protons:

$$6m_\text{p} + 6m_\text{n} = 6\times1.007\,825\,\text{u} + 6\times1.008\,665\,\text{u} = 12.098\,940\,\text{u}$$

Subtract the mass of ^{12}C from this result:

$$(6m_\text{p} + 6m_\text{n}) - m_{^{12}\text{C}} = 12.098\,940\,\text{u} - 12\,\text{u} = 0.098\,940\,\text{u}$$

Multiply the mass difference by c^2 and convert to MeV:

$$E_b = (\Delta m)c^2 = (0.098\ 940\,\mathrm{u})c^2\left(\frac{931.5\,\mathrm{MeV}/c^2}{\mathrm{u}}\right) = \boxed{92.2\,\mathrm{MeV}}$$

and the binding energy per nucleon is $\dfrac{E_b}{A} = \dfrac{92.2\,\mathrm{MeV}}{12} = \boxed{7.68\,\mathrm{MeV}}$

(*b*) For ^{56}Fe, Z = 26 and N = 30. Add the mass of the neutrons to that of the protons:

$$26m_p + 30m_n = 26\times 1.007\ 825\,\mathrm{u} + 30\times 1.008\ 665\,\mathrm{u} = 56.463\ 400\,\mathrm{u}$$

Subtract the mass of ^{56}Fe from this result:

$$(26m_p + 30m_n) - m_{^{12}\mathrm{C}} = 56.463\ 400\,\mathrm{u} - 55.934\ 942\,\mathrm{u} = 0.528\ 458\,\mathrm{u}$$

Multiply the mass difference by c^2 and convert to MeV:

$$E_b = (\Delta m)c^2 = (0.528\ 458\,\mathrm{u})c^2\left(\frac{931.5\,\mathrm{MeV}/c^2}{\mathrm{u}}\right) = \boxed{492\,\mathrm{MeV}}$$

and the binding energy per nucleon is $\dfrac{E_b}{A} = \dfrac{492\,\mathrm{MeV}}{56} = \boxed{8.79\,\mathrm{MeV}}$

(*c*) For ^{238}U, Z = 92 and N = 146. Add the mass of the neutrons to that of the protons:

$$92m_p + 146m_n = 92\times 1.007\ 825\,\mathrm{u} + 146\times 1.008\ 665\,\mathrm{u} = 239.984\ 990\,\mathrm{u}$$

Subtract the mass of ^{238}U from this result:

$$(92m_p + 146m_n) - m_{^{238}\mathrm{U}} = 239.984\ 990\,\mathrm{u} - 238.050\ 783\,\mathrm{u} = 1.934\ 207\,\mathrm{u}$$

Multiply the mass difference by c^2 and convert to MeV:

$$E_b = (\Delta m)c^2 = (1.934\ 207\,\mathrm{u})c^2\left(\frac{931.5\,\mathrm{MeV}/c^2}{\mathrm{u}}\right) = \boxed{1802\,\mathrm{MeV}}$$

and the binding energy per nucleon is $\dfrac{E_b}{A} = \dfrac{1802\,\mathrm{MeV}}{238} = \boxed{7.57\,\mathrm{MeV}}$

16 • Calculate the binding energy and the binding energy per nucleon from the masses given in Table 40-1 for (*a*) ^{6}Li, (*b*) ^{39}K, and (*c*) ^{208}Pb.

Picture the Problem To find the binding energy of a nucleus we add the mass of its neutrons to the mass of its protons and then subtract the mass of the nucleus and multiply by c^2. The binding energy per nucleon is the ratio of the binding energy to the mass number of the nucleus.

(*a*) For ^{6}Li, Z = 3 and N = 3. Add the mass of the neutrons to that of the protons:

$$3m_\mathrm{p} + 3m_\mathrm{n} = 3\times 1.007\ 825\,\mathrm{u} + 3\times 1.008\ 665\,\mathrm{u} = 6.049\ 470\,\mathrm{u}$$

Subtract the mass of ^{6}Li from this result:

$$(3m_\mathrm{p} + 3m_\mathrm{n}) - m_{^6\mathrm{L}i} = 6.049\ 470\,\mathrm{u} - 6.015\,122\,\mathrm{u} = 0.034\ 348\,\mathrm{u}$$

Multiply the mass difference by c^2 and convert to MeV:

$$E_\mathrm{b} = (\Delta m)c^2 = (0.034\ 348\,\mathrm{u})c^2\left(\frac{931.5\,\mathrm{MeV}/c^2}{\mathrm{u}}\right) = \boxed{32.0\,\mathrm{MeV}}$$

and the binding energy per nucleon is $\dfrac{E_\mathrm{b}}{A} = \dfrac{32.0\,\mathrm{MeV}}{6} = \boxed{5.33\,\mathrm{MeV}}$

(*b*) For ^{39}K, Z = 19 and N = 20. Add the mass of the neutrons to that of the protons:

$$19m_\mathrm{p} + 20m_\mathrm{n} = 19\times 1.007\ 825\,\mathrm{u} + 20\times 1.008\ 665\,\mathrm{u} = 39.321\,975\,\mathrm{u}$$

Subtract the mass of ^{39}K from this result:

$$(19m_\mathrm{p} + 20m_\mathrm{n}) - m_{^{39}\mathrm{K}} = 39.321\,975\,\mathrm{u} - 38.963\ 707\,\mathrm{u} = 0.358\ 268\,\mathrm{u}$$

Multiply the mass difference by c^2 and convert to MeV:

$$E_\mathrm{b} = (\Delta m)c^2 = (0.358\ 268\,\mathrm{u})c^2\left(\frac{931.5\,\mathrm{MeV}/c^2}{\mathrm{u}}\right) = \boxed{334\,\mathrm{MeV}}$$

and the binding energy per nucleon is $\dfrac{E_\mathrm{b}}{A} = \dfrac{334\,\mathrm{MeV}}{39} = \boxed{8.56\,\mathrm{MeV}}$

(*c*) For ^{208}Pb, Z = 82 and N = 126. Add the mass of the neutrons to that of the protons:

$$82m_{\text{p}} + 126m_{\text{n}} = 82 \times 1.007\ 825\,\text{u} + 126 \times 1.008\ 665\,\text{u} = 209.733\ 440\,\text{u}$$

Subtract the mass of ^{208}Pb from this result:

$$\left(82m_{\text{p}} + 126m_{\text{n}}\right) - m_{^{208}\text{Pb}} = 209.733\ 440\,\text{u} - 207.976\ 636\,\text{u} = 1.756\ 804\,\text{u}$$

Multiply the mass difference by c^2 and convert to MeV:

$$E_{\text{b}} = (\Delta m)c^2 = (1.756\ 804\,\text{u})c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right) = \boxed{1636\,\text{MeV}}$$

and the binding energy per nucleon is $\dfrac{E_{\text{b}}}{A} = \dfrac{1636\,\text{MeV}}{208} = \boxed{7.87\,\text{MeV}}$

17 • Use the radius formula $R = R_0 A^{1/3}$ (Equation 40-1), where R_0 = 1.2 fm, to compute the radii of the following nuclei: (*a*) ^{16}O, (*b*) ^{56}Fe, and (*c*) ^{197}Au.

Picture the Problem The nuclear radius is given by $R = R_0 A^{1/3}$ where R_0 = 1.2 fm.

(*a*) The radius of ^{16}O is: $R_{^{16}\text{O}} = (1.2\,\text{fm})(16)^{1/3} = \boxed{3.0\,\text{fm}}$

(*b*) The radius of ^{56}Fe is: $R_{^{56}\text{Fe}} = (1.2\,\text{fm})(56)^{1/3} = \boxed{4.6\,\text{fm}}$

(*c*) The radius of ^{197}Au is: $R_{^{197}\text{Au}} = (1.2\,\text{fm})(197)^{1/3} = \boxed{7.0\,\text{fm}}$

18 • During a fission process, a ^{239}Pu nucleus splits into two nuclei whose mass number ratio is 3 to 1. Calculate the radii of the nuclei formed during this process.

Picture the Problem The nuclear radius is given by $R = R_0 A^{1/3}$ where R_0 = 1.2 fm.

The radii of the daughter nuclei are given by:

$$R = R_0 A^{1/3} \qquad (1)$$

Because the ratio of the mass numbers of the daughter nuclei is 3 to 1:

$$A_1 = \frac{3}{4}(239) \text{ and } A_2 = \frac{1}{4}(239)$$

Substitute in equation (1) to obtain:

$$R_1 = (1.2\,\text{fm})\left(\frac{3\times 239}{4}\right)^{1/3} = \boxed{6.8\,\text{fm}}$$

and

$$R_2 = (1.2\,\text{fm})\left(\frac{239}{4}\right)^{1/3} = \boxed{4.7\,\text{fm}}$$

19 •• [SSM] The neutron, when isolated from an atomic nucleus, decays into a proton, an electron, and an antineutrino as follows: $\text{n} \to {}^1\text{H} + \text{e}^- + \bar{\nu}$. The thermal energy of a neutron is of the order of *kT*, where *k* is the Boltzmann constant. (*a*) In both joules and electron volts, calculate the energy of a thermal neutron at 25ºC. (*b*) What is the speed of this thermal neutron? (*c*) A beam of monoenergetic thermal neutrons is produced at 25ºC and has an intensity *I*. After traveling 1350 km, the beam has an intensity of $\frac{1}{2}I$. Using this information, estimate the half-life of the neutron. Express your answer in minutes.

Picture the Problem The speed of the neutrons can be found from their thermal energy. The time taken to reduce the intensity of the beam by one-half, from *I* to *I*/2, is the half-life of the neutron. Because the beam is monoenergetic, the neutrons all travel at the same speed.

(*a*) The thermal energy of the neutron is:

$$\begin{aligned} E_{\text{thermal}} &= kT \\ &= (1.381\times 10^{-23}\ \text{J/K})(25+273)\text{K} \\ &= \boxed{4.11\times 10^{-21}\ \text{J}} \\ &= 4.11\times 10^{-21}\ \text{J}\times\frac{1\text{eV}}{1.602\times 10^{-19}\ \text{J}} \\ &= \boxed{25.7\,\text{meV}} \end{aligned}$$

(*b*) Equate E_{thermal} and the kinetic energy of the neutron to obtain:

$$E_{\text{thermal}} = \tfrac{1}{2}m_\text{n}v^2 \Rightarrow v = \sqrt{\frac{2E_{\text{thermal}}}{m_\text{n}}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{2(4.11\times 10^{-21}\ \text{J})}{1.673\times 10^{-27}\ \text{kg}}} = \boxed{2.22\,\text{km/s}}$$

(*c*) Relate the half-life, $t_{1/2}$, to the speed of the neutrons in the beam:

$$t_{1/2} = \frac{x}{v}$$

Substitute numerical values and evaluate $t_{1/2}$:

$$t_{1/2} = \frac{1350\text{ km}}{2.22\text{ km/s}} = 608\text{ s} \times \frac{1\text{min}}{60\text{ s}} = \boxed{10.1\text{min}}$$

20 • Use the radius formula $R = R_0 A^{1/3}$ (Equation 40-1), where R_0 = 1.2 fm, for the radius of a spherical nucleus to calculate the density of nuclear matter. Express your answer in grams per cubic centimeter.

Picture the Problem We can use the definition of density, the equation for the volume of a sphere, and the given approximation to calculate the density of nuclear matter in grams per cubic centimeter.

Express the density of a spherical nucleus:

$$\rho = \frac{m}{V}$$

The approximate mass is:

$$m = \left(1.66 \times 10^{-27}\text{ kg}\right)A$$

The volume of the nucleus is given by:

$$V = \tfrac{4}{3}\pi\left(R_0 A^{1/3}\right)^3 = \tfrac{4}{3}\pi R_0^3 A$$

Substitute for m and V to obtain:

$$\rho = \frac{\left(1.66 \times 10^{-27}\text{ kg}\right)A}{\tfrac{4}{3}\pi R_0^3 A} = \frac{3\left(1.66 \times 10^{-27}\text{ kg}\right)}{4\pi R_0^3}$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{3\left(1.66 \times 10^{-27}\text{ kg}\right)}{4\pi\left(1.2\text{ fm}\right)^3} = 2.29 \times 10^{17}\text{ kg/m}^3 = \boxed{2.3 \times 10^{14}\text{ g/cm}^3}$$

21 •• **[SSM]** In 1920, 12 years before the discovery of the neutron, Ernest Rutherford argued that proton–electron pairs might exist in the confines of the nucleus in order to explain the mass number, A, being greater than the nuclear charge, Z. He also used this argument to account for the source of beta particles in radioactive decay. Rutherford's scattering experiments in 1910 showed that the nucleus had a diameter of approximately 10 fm. Using this nuclear diameter, the uncertainty principle, and that beta particles have an energy range of 0.02 MeV to 3.40 MeV, show why the hypothetical electrons cannot be confined to a region occupied by the nucleus.

Picture the Problem The Heisenberg uncertainty principle relates the uncertainty in position, Δx, to the uncertainty in momentum, Δp, by $\Delta x\Delta p \geq \frac{1}{2}\hbar$.

Solve the Heisenberg equation for Δp:

$$\Delta p \approx \frac{\hbar}{2\Delta x}$$

Assuming that electrons are contained within the nucleus, the uncertainty in their momenta must be:

$$\Delta p \approx \frac{1.05\times10^{-34}\ \mathrm{J\cdot s}}{2\left(10\times10^{-15}\ \mathrm{m}\right)} = 5.25\times10^{-21}\ \mathrm{kg\cdot m/s}$$

The kinetic energy of the electron is given by:

$$K = pc$$

Substitute numerical values and evaluate K for a nuclear electron:

$$K = \left(5.25\times10^{-21}\ \mathrm{kg\cdot m/s}\right)\left(2.998\times10^{8}\ \mathrm{m/s}\right) = 1.58\times10^{-12}\ \mathrm{J}\times\frac{1\mathrm{eV}}{1.602\times10^{-19}\ \mathrm{J}}$$

$$\approx 10\ \mathrm{MeV}$$

This result contradicts experimental observations that show that the energy of electrons in unstable atoms is of the order of 1 to 1000 eV. Hence the premise on which it is based (that electrons are contained within the nucleus) must be false.

22 •• Consider the following fission process: ${}^{236}_{92}\mathrm{U} + \mathrm{n} \rightarrow {}^{95}_{37}\mathrm{Rb} + {}^{137}_{55}\mathrm{Cs} + 4\mathrm{n}$. Determine the electrostatic potential energy, in MeV, of the reaction products when the surfaces of the ${}^{95}\mathrm{Rb}$ nucleus and the ${}^{137}\mathrm{Cs}$ nucleus are just touching immediately after being formed during the fission process.

Picture the Problem The separation of the nuclei when they are just touching is the sum of their radii. The radius of a nucleus whose atomic number is A is given by $R = R_0A^{1/3}$, where R_0 = 1.2 fm.

The electrostatic potential energy of the system is given by:

$$U = k\frac{q_1q_2}{R} = k\frac{\left(Z_{\mathrm{Rb}}e\right)\left(Z_{\mathrm{Cs}}e\right)}{R_{\mathrm{Rb}} + R_{\mathrm{Cs}}}$$

where R is the distance from the center of the ${}^{95}\mathrm{Rb}$ nucleus to the center of the ${}^{137}\mathrm{Cs}$ nucleus.

The radii of the nuclei are:

$$R_{\mathrm{Rb}} = R_{\mathrm{o}}A_{\mathrm{Rb}}^{1/3} \text{ and } R_{\mathrm{Cs}} = R_{\mathrm{o}}A_{\mathrm{Cs}}^{1/3}$$

Substitute for R_{Rb} and R_{Cs} and simplify to obtain:

$$U = ke^2 \frac{(Z_{Rb})(Z_{Cs})}{R_o A_{Rb}^{1/3} + R_o A_{Cs}^{1/3}} = \frac{ke^2}{R_o} \frac{(Z_{Rb})(Z_{Cs})}{\left(A_{Rb}^{1/3} + A_{Cs}^{1/3}\right)}$$

Substitute numerical values and evaluate U:

$$U = \frac{\left(8.988\times10^9\ \text{Nm}^2/\text{C}^2\right)\left(1.602\times10^{-19}\ \text{C}\right)^2}{\left(1.2\times10^{-15}\ \text{m}\right)} \frac{(37)(55)}{\left(95^{1/3} + 137^{1/3}\right)}$$
$$= 4.026\times10^{-11}\ \text{J}\times\frac{1\text{eV}}{1.602\times10^{-19}\ \text{J}} = \boxed{0.25\ \text{GeV}}$$

Radioactivity

23 • Homer enters the visitors’ chambers, and his Geiger beeper sounds. He shuts off the beeper, removes the device from his shoulder patch, and holds it near the only new object in the room—an orb that is to be presented as a gift from the visiting Cartesians. Pushing a button marked ″monitor, ″ Homer reads that the device is reading a counting rate of 4000 counts/s above the background counting rate. After 10 min, the counting rate has dropped to 1000 counts/s above the background rate. (*a*) What is the half-life of the source? (*b*) How high will the counting rate be counting above the background counting rate 20 min after the monitoring device was switched on?

Picture the Problem The counting rate, as a function of the number of half-lives *n*, is given by $R = \left(\frac{1}{2}\right)^n R_0$, where R_0 = 4000 counts/s.

(*a*) The counting rate after *n* half-lives is:

$$R = \left(\tfrac{1}{2}\right)^n R_0 \Rightarrow n = \frac{\ln(R/R_0)}{\ln\left(\frac{1}{2}\right)}$$

Substitute numerical values and evaluate *n*:

$$n = \frac{\ln\left(\dfrac{1000\,\text{counts/s}}{4000\,\text{counts/s}}\right)}{\ln\left(\frac{1}{2}\right)} = 2$$

Because there are two half-lives in 10 min:

$$t_{1/2} = \boxed{5\,\text{min}}$$

(*b*) At the end of 4 half-lives:

$$R = \left(\tfrac{1}{2}\right)^4 (4000\,\text{counts/s}) = \boxed{250\,\text{Bq}}$$

24 • A certain source gives 2000 counts/s at time $t = 0$. Its half-life is 2.0 min. How many counts per second will it give after (*a*) 4.0 min, (*b*) 6.0 min, and (*c*) 8.0 min?

Picture the Problem The counting rate, as a function of the number of half-lives n, is given by $R = \left(\frac{1}{2}\right)^n R_0$.

(*a*) When t = 4.0 min, two half-lives will have passed and n = 2:

$$R = \left(\tfrac{1}{2}\right)^2 (2000\,\text{counts/s}) = \boxed{500\,\text{Bq}}$$

(*b*) When t = 6.0 min, three half-lives will have passed and n = 3:

$$R = \left(\tfrac{1}{2}\right)^3 (2000\,\text{counts/s}) = \boxed{250\,\text{Bq}}$$

(*c*) When t = 8.0 min, four half-lives will have passed and n = 4:

$$R = \left(\tfrac{1}{2}\right)^4 (2000\,\text{counts/s}) = \boxed{125\,\text{Bq}}$$

25 • The counting rate from a radioactive source is 8000 counts/s at time t = 0, and 10 min later the rate is 1000 counts/s. (*a*) What is the half-life? (*b*) What is the decay constant? (*c*) What is the counting rate after 20 min?

Picture the Problem The counting rate, as a function of the number of half-lives n, is given by $R = \left(\frac{1}{2}\right)^n R_0$ and the decay constant λ is related to the half-life by $t_{1/2} = \ln(2)/\lambda$.

(*a*) Relate the counting rate at time t = 10 min to the counting rate at t = 0:

$$R_{10\,\text{min}} = \left(\tfrac{1}{2}\right)^n R_0 \Rightarrow n = \frac{\ln\left(R_{10\,\text{min}}/R_0\right)}{\ln\left(\frac{1}{2}\right)}$$

Substitute numerical values and evaluate n:

$$n = \frac{\ln\left(\dfrac{1000\,\text{counts/s}}{8000\,\text{counts/s}}\right)}{\ln\left(\frac{1}{2}\right)} = 3$$

Therefore, 3 half-lives have passed in 10 min:

$$3t_{1/2} = 10\,\text{min} \Rightarrow t_{1/2} = \boxed{200\,\text{s}}$$

(*b*) The decay constant λ is related to the half-life by:

$$t_{1/2} = \frac{\ln(2)}{\lambda} \Rightarrow \lambda = \frac{\ln(2)}{t_{1/2}}$$

Substitute for $t_{1/2}$ and evaluate λ:

$$\lambda = \frac{\ln(2)}{200\,\text{s}} = \boxed{3.5\times10^{-3}\,\text{s}^{-1}}$$

(*c*) Six half-lives will have passed in 20 min:

$$R_{20\,\text{min}} = \left(\tfrac{1}{2}\right)^6 (8000\,\text{Bq}) = \boxed{125\,\text{Bq}}$$

26 • The half-life of radium is 1620 y. Calculate the number of disintegrations per second of 1.00 g of radium and show that the disintegration rate is approximately 1.0 Ci.

Picture the Problem We can use $R = \lambda N_0 e^{-\lambda t}$ to show that the disintegration rate is approximately 1.0 Ci.

The decay rate is given by:

$$R = \lambda N_0 e^{-\lambda t}$$

where N_0 is the number of nuclei at $t = 0$.

The decay constant λ is related to the half-life by:

$$t_{1/2} = \frac{\ln(2)}{\lambda} \Rightarrow \lambda = \frac{\ln(2)}{t_{1/2}}$$

Substitute for $t_{1/2}$ and evaluate λ:

$$\lambda = \frac{\ln(2)}{1620\,\text{y}} = 4.28\times10^{-4}\ \text{y}^{-1}\times\frac{1\,\text{y}}{31.56\,\text{Ms}}$$
$$= 1.356\times10^{-11}\ \text{s}^{-1}$$

The number of radioactive nuclei N_0 at $t = 0$ can be found from Avogadro's number N_A, the mass m_{Ra} of the sample, and the molar mass M of the sample:

$$\frac{N_0}{N_A} = \frac{m_{Ra}}{M} \Rightarrow N_0 = N_A\frac{m_{Ra}}{M}$$

Substitute numerical values and evaluate N_0:

$$N_0 = \left(6.022\times10^{23}\,\text{nuclei/mol}\right)\left(\frac{1.00\ \text{g}}{226\ \text{g/mol}}\right) = 2.664\times10^{21}\ \text{nuclei}$$

Substitute numerical values for λ and N_0 and evaluate R:

$$R = \left(1.356\times10^{-11}\ \text{s}^{-1}\right)\left(2.664\times10^{21}\right)e^{-\left(1.356\times10^{-11}\ \text{s}^{-1}\right)(0)} = 3.61\times10^{10}\ \text{s}^{-1}$$
$$\approx 3.7\times10^{10}\ \text{s}^{-1} = \boxed{1.0\ \text{Ci}}$$

27 • A radioactive piece of silver foil ($t_{1/2}$ = 2.4 min) is placed near a Geiger counter and 1000 counts/s are observed at time t = 0. (*a*) What is the counting rate at t = 2.4 min and at t = 4.8 min? (*b*) If the counting efficiency is 20 percent, how many radioactive silver nuclei are there at time t = 0? At time t = 2.4 min? (*c*) At what time will the counting rate be about 30 counts/s?

Picture the Problem We can use $R=\left(\frac{1}{2}\right)^n R_0$ to relate the counting rate R to the number of half-lives n that have passed since $t = 0$. The detection efficiency depends on the probability that a radioactive decay particle will enter the detector and the probability that upon entering the detector it will produce a count. If the efficiency is 20 percent, the decay rate must be 5 times the counting rate.

(*a*) When $t = 2.4$ min, $n = 1$ and:

$$R_{2.4\,\text{min}}=\left(\tfrac{1}{2}\right)^1(1000\,\text{counts/s})=\boxed{500\,\text{Bq}}$$

When $t = 4.8$ min, $n = 2$ and:

$$R_{4.8\,\text{min}}=\left(\tfrac{1}{2}\right)^2(1000\,\text{counts/s})=\boxed{250\,\text{Bq}}$$

(*b*) The number of radioactive nuclei is related to the decay rate R, and the decay constant λ:

$$R=\lambda N\Rightarrow N=\frac{R}{\lambda}\qquad(1)$$

The decay constant is related to the half-life:

$$\lambda=\frac{0.693}{t_{1/2}}=\frac{0.693}{2.4\,\text{min}}=\frac{0.693}{144\,\text{s}}=4.813\times10^{-3}\,\text{s}^{-1}$$

Calculate the decay rate at $t = 0$ from the counting rate:

$$R_0=5\times1000\,\text{counts/s}=5000\,\text{s}^{-1}$$

Substitute in equation (1) and evaluate N_0 at $t = 0$:

$$N_0=\frac{R_0}{\lambda}=\frac{5000\,\text{s}^{-1}}{4.813\times10^{-3}\,\text{s}^{-1}}=\boxed{1.0\times10^6}$$

Calculate the decay rate at $t = 2.4$ min from the counting rate:

$$R_{2.4\,\text{min}}=5\times500\,\text{counts/s}=2500\,\text{s}^{-1}$$

Substitute in equation (1) and evaluate $N_{2.4\text{ min}}$:

$$N_{2.4\,\text{min}}=\frac{R_{2.4\,\text{min}}}{\lambda}=\frac{2500\,\text{s}^{-1}}{4.813\times10^{-3}\,\text{s}^{-1}}=\boxed{5.2\times10^5}$$

(*c*) The time at which the counting rate will be about 30 counts/s is the product of the number of half-lives that will have passed and the half-life:

$$t=nt_{1/2}\qquad(2)$$

The counting rate R after n half-lives is related to the counting rate at $t = 0$ by:

$$R = \left(\tfrac{1}{2}\right)^n R_0 \Rightarrow n = \frac{\ln(R/R_0)}{\ln\left(\tfrac{1}{2}\right)}$$

Substitute numerical values and evaluate n:

$$n = \frac{\ln(30\,\text{counts/s}/1000\,\text{counts/s})}{\ln\left(\tfrac{1}{2}\right)} = 5.059$$

Substitute numerical values for n and $t_{1/2}$ in equation (2) and evaluate t:

$$t = (5.059)(2.4\,\text{min}) = \boxed{12\text{ min}}$$

28 • Use Table 40-1 to calculate the energy release, in MeV, for the α decay of (*a*) ^{226}Ra and (*b*) ^{242}Pu.

Picture the Problem Knowing each of these reactions, we can use Table 40-1 to find the differences in the masses of the nuclei and then convert this difference into the energy released in each reaction.

(*a*) Write the reaction:

$$^{226}\text{Ra} \rightarrow {}^{222}\text{Rn} + {}^{4}\text{He}$$

Use Table 40-1 to find ΔE:

$$\Delta E = (226.025\ 403\,\text{u} - 222.017\ 571\,\text{u} - 4.002\ 603\,\text{u})c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$

$$= \boxed{4.87\,\text{MeV}}$$

(*b*) Write the reaction:

$$^{242}\text{Pu} \rightarrow {}^{238}\text{U} + {}^{4}\text{He}$$

Use Table 40-1 to find ΔE:

$$\Delta E = (242.058\ 737\,\text{u} - 238.050\ 783\,\text{u} - 4.002\ 603\,\text{u})c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$

$$= \boxed{4.98\,\text{MeV}}$$

29 •• **[SSM]** Plutonium is very toxic to the human body. Once it enters the body it collects primarily in the bones, although it also can be found in other organs. Red blood cells are synthesized within the marrow of the bones. The isotope ^{239}Pu is an alpha emitter that has a half-life of 24 360 years. Because alpha particles are an ionizing radiation, the blood-making ability of the marrow is, in time, destroyed by the presence of ^{239}Pu. In addition, many kinds of cancers will

also develop in the surrounding tissues because of the ionizing effects of the alpha particles. (*a*) If a person accidentally ingested 2.0 μg of ^{239}Pu and all of it is absorbed by the bones of the person, how many alpha particles are produced per second within the body of the person? (*b*) When, in years, will the activity be 1000 alpha particles per second?

Picture the Problem Each ^{239}Pu nucleus emits an alpha particle whose activity, *A*, depends on the decay constant of ^{239}Pu and on the number *N* of nuclei present in the ingested ^{239}Pu. We can find the decay constant from the half-life and the number of nuclei present from the mass ingested and the atomic mass of ^{239}Pu. Finally, we can use the dependence of the activity on time to find the time at which the activity will be 1000 alpha particles per second.

(*a*) The activity of the nuclei present in the ingested ^{239}Pu is given by:

$$R = \lambda N \qquad (1)$$

Find the constant for the decay of ^{239}Pu:

$$\lambda = \frac{\ln(2)}{t_{1/2}} = \frac{0.693}{(24360\,\text{y})(31.56\,\text{Ms/y})} = 9.016\times10^{-13}\,\text{s}^{-1}$$

Express the number of nuclei *N* present in the mass m_{Pu} of ^{239}Pu ingested:

$$\frac{N}{N_{\text{A}}} = \frac{m_{\text{Pu}}}{M_{\text{Pu}}} \Rightarrow N = m_{\text{Pu}}\frac{N_{\text{A}}}{M_{\text{Pu}}}$$

where M_{Pu} is the atomic mass of ^{239}Pu.

Substitute numerical values and evaluate *N*:

$$N = (2.0\,\mu\text{g})\left(\frac{6.022\times10^{23}\,\text{nuclei/mol}}{239\,\text{g/mol}}\right) = 5.039\times10^{15}\,\text{nuclei}$$

Substitute numerical values in equation (1) and evaluate *A*:

$$R = (9.016\times10^{-13}\,\text{s}^{-1})(5.039\times10^{15}\,\alpha) = 4.543\times10^{3}\,\alpha/\text{s} = \boxed{4.5\times10^{3}\,\alpha/\text{s}}$$

(*b*) The activity varies with time according to:

$$R = R_0 e^{-\lambda t} \Rightarrow t = \frac{\ln\left(\dfrac{R}{R_0}\right)}{-\lambda}$$

Substitute numerical values and evaluate *t*:

$$t = \frac{\ln\left(\dfrac{1000\,\alpha/\text{s}}{4.543\times10^{3}\,\alpha/\text{s}}\right)}{-(9.016\times10^{-13}\,\text{s}^{-1})\left(\dfrac{31.56\,\text{Ms}}{\text{y}}\right)} = \boxed{5.3\times10^{4}\,\text{y}}$$

30 •• Consider an alpha-emitting parent nucleus ${}^{A}_{Z}X$ initially at rest. The nucleus decays into a daughter nucleus Y and an alpha particle as follows: ${}^{A}_{Z}X \rightarrow {}^{A-4}_{Z-2}Y + {}^{4}_{2}\alpha + Q$. (*a*) Show that the alpha particle has a kinetic energy of $(A - 4)Q/A$. (*b*) Show that the kinetic energy of the recoiling daughter nucleus is given by $K_Y = 4Q/A$.

Picture the Problem We can use conservation of energy and conservation of linear momentum to relate the momenta and kinetic energies of the nuclei to the decay's Q value.

(*a*) Express the kinetic energies of the alpha particle and daughter nucleus:

$$K_\alpha = \tfrac{1}{2}m_\alpha v_\alpha^2 = \frac{p_\alpha^2}{2m_\alpha} \qquad (1)$$

and

$$K_Y = \tfrac{1}{2}m_Y v_Y^2 = \frac{p_Y^2}{2m_Y} \qquad (2)$$

Solve equations (1) and (2) for p_α^2 and p_D^2:

$p_\alpha^2 = 2m_\alpha K_\alpha$ and $p_Y^2 = 2m_Y K_Y$

From the conservation of linear momentum we have:

$\vec{p}_i = \vec{p}_f$

or, because the parent is initially at rest, $0 = p_\alpha - p_Y$ and $p_\alpha = p_Y$.

Because the momenta are equal:

$$2m_Y K_Y = 2m_\alpha K_\alpha$$

Solving for K_Y and simplifying gives:

$$K_Y = \frac{m_\alpha}{m_Y}K_\alpha = \frac{4}{A-4}K_\alpha$$

Because the daughter nucleus and the alpha particle share the Q-value:

$$Q = K_Y + K_\alpha = \frac{4}{A-4}K_\alpha + K_\alpha = \left(\frac{4}{A-4}+1\right)K_\alpha = \left(\frac{A}{A-4}\right)K_\alpha$$

Solve for K_α to obtain:

$$K_\alpha = \boxed{\left(\frac{A-4}{A}\right)Q}$$

(*b*) Substituting for K_α in the expression for Q yields:

$$Q = K_Y + \left(\frac{A-4}{A}\right)Q$$

Solving for K_Y gives:

$$K_Y = Q - \left(\frac{A-4}{A}\right)Q = \boxed{\frac{4Q}{A}}$$

31 • [SSM] The fissile material ^{239}Pu is an alpha emitter. Write the reaction that describes ^{239}Pu undergoing alpha decay. Given that ^{239}Pu, ^{235}U, and an alpha particle have respective masses of 239.052 156 u, 235.043 923 u, and 4.002 603 u, use the relations appearing in Problem 30 to calculate the kinetic energies of the alpha particle and the recoiling daughter nucleus.

Picture the Problem We can write the equation of the decay process by using the fact that the post-decay sum of the *Z* and *A* numbers must equal the pre-decay values of the parent nucleus. The *Q* value in the equations from Problem 30 is given by $Q = -(\Delta m)c^2$.

^{239}Pu undergoes alpha decay according to:

$$\boxed{{}^{239}_{94}\text{Pu} \to {}^{235}_{92}\text{U} + {}^{4}_{2}\alpha + Q}$$

The *Q* value, in MeV, for the decay is given by:

$$Q = \left[\left(m_{\text{Pu}}\right) - \left(m_{\text{U}} + m_\alpha\right)\right]c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$

Substitute numerical values and evaluate *Q*:

$$Q = \left[(239.052\,156\,\text{u}) - (235.043\,923\,\text{u} + 4.002\,603\,\text{u})\right]c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$
$$= \boxed{5.24\,\text{MeV}}$$

From Problem 30, the kinetic energy of the alpha particle is given by:

$$K_\alpha = \left(\frac{A-4}{A}\right)Q$$

Substitute numerical values and evaluate K_α:

$$K_\alpha = \left(\frac{239-4}{239}\right)(5.24\,\text{MeV})$$
$$= \boxed{5.15\,\text{MeV}}$$

From Problem 30, the kinetic energy of ^{235}U is given by:

$$K_{\text{U}} = \frac{4Q}{A}$$

Substitute numerical values and evaluate $K_{^{235}\text{U}}$:

$$K_{^{235}\text{U}} = \frac{4(5.24\,\text{MeV})}{235} = \boxed{89.2\,\text{keV}}$$

32 • Through a friend in the security department at the museum, Angela obtains a sample of a wooden tool handle that contains 175 g of carbon. The decay rate of the ^{14}C in the sample is 8.1 Bq. How long ago was the wood in the handle last alive?

Picture the Problem We can find the age of the sample using $R_n = \left(\frac{1}{2}\right)^n R_0$ to find n and then applying $t = nt_{1/2}$.

Express the age of the bone in terms of the half-life of ^{14}C and the number n of half-lives that have elapsed:

$$t = nt_{1/2} \qquad (1)$$

The decay rate R_n after n half-lives is related to the counting rate R_0 at $t = 0$ by:

$$R_n = \left(\tfrac{1}{2}\right)^n R_0 \Rightarrow n = \frac{\ln(R/R_0)}{\ln\left(\frac{1}{2}\right)}$$

Because there are 15.0 decays per minute per gram of carbon in a living organism:

$$R_0 = 15.0\,\frac{\text{decays}}{\text{min}\cdot\text{g}}\times\frac{1\,\text{min}}{60\,\text{s}}\times 175\,\text{g} = 43.75\,\text{Bq}$$

Substitute numerical values for R and R_0 and evaluate n:

$$n = \frac{\ln\left(\dfrac{8.1\,\text{Bq}}{43.75\,\text{Bq}}\right)}{\ln\left(\frac{1}{2}\right)} = 2.433$$

Substitute numerical values in equation (1) and evaluate t:

$$t = (2.433)(5730\,\text{y}) \approx \boxed{14{,}000\,\text{y}}$$

33 • A sample of a radioactive isotope is found to have an activity of 115.0 Bq immediately after it is pulled from the reactor that formed the isotope. Its activity 2 h 15 min later is measured to be 85.2 Bq. (*a*) Calculate the decay constant and the half-life of the sample. (*b*) How many radioactive nuclei were there in the sample initially?

Picture the Problem We can solve $R = R_0 e^{-\lambda t}$ for λ to find the decay constant of the sample and use $t_{1/2} = \dfrac{\ln 2}{\lambda}$ to find its half-life. The number of radioactive nuclei in the sample initially can be found from $R_0 = \lambda N_0$.

(*a*) The decay rate is given by:

$$R = R_0 e^{-\lambda t} \Rightarrow \lambda = \frac{\ln\left(\dfrac{R}{R_0}\right)}{-t}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{\ln\left(\frac{85.2\,\text{Bq}}{115.0\,\text{Bq}}\right)}{-2.25\,\text{h}} = \boxed{0.133\,\text{h}^{-1}}$$

The half-life is related to the decay constant:

$$t_{1/2} = \frac{\ln(2)}{\lambda} = \frac{\ln(2)}{0.133\,\text{h}^{-1}} = \boxed{5.20\,\text{h}}$$

(b) The number N_0 of radioactive nuclei in the sample initially is related to the decay constant λ and the initial decay rate R_0:

$$R_0 = \lambda N_0 \Rightarrow N_0 = \frac{R_0}{\lambda}$$

Substitute numerical values and evaluate N_0:

$$N_0 = \frac{115\,\text{Bq}}{0.133\,\text{h}^{-1} \times \frac{1\,\text{h}}{3600\,\text{s}}} = \boxed{3.11\times10^{6}}$$

34 •• A 1.00-mg sample of substance that has an atomic mass of 59.934 u and emits β particles has an activity of 1.131 Ci. Find the decay constant for this substance in reciprocal seconds and find the half-life in years.

Picture the Problem The decay constant λ can be found from the decay rate R and the number of radioactive nuclei N at the moment of interest and the half-life, in turn, can be found from the decay constant.

The decay rate R is related to the decay constant λ and the number of radioactive nuclei N at the moment of interest:

$$R = \lambda N \Rightarrow \lambda = \frac{R}{N} \qquad (1)$$

The number of radioactive nuclei N at the moment of interest can be found from Avogadro's number, the mass m of the sample, and the molar mass M of the sample:

$$\frac{N}{N_A} = \frac{m}{M} \Rightarrow N = N_A\frac{m}{M}$$

Substitute numerical values and evaluate N:

$$N = \left(6.022\times10^{23}\ \text{nuclei/mol}\right)\frac{1.00\ \text{mg}}{59.934\,\text{g/mol}} = 1.004\times10^{19}\ \text{nuclei}$$

Substitute numerical values in equation (1) and evaluate λ:

$$\lambda = \frac{1.131\,\text{Ci} \times \dfrac{3.7\times10^{10}\ \text{Bq}}{\text{Ci}}}{1.004\times10^{19}\ \text{nuclei}} = \boxed{4.17\times10^{-9}\ \text{s}^{-1}}$$

Find the half-life from the decay constant:

$$t_{1/2} = \frac{\ln(2)}{\lambda} = \frac{\ln(2)}{4.17\times10^{-9}\ \text{s}^{-1}} = 1.67\times10^{8}\ \text{s}\times\frac{1\,\text{y}}{31.56\,\text{Ms}} = \boxed{5.27\,\text{y}}$$

35 •• [SSM] Radiation has been used for a long time in medical therapy to control the development and growth of cancer cells. Cobalt-60, a gamma emitter that emits photons that have energies of 1.17 MeV and 1.33 MeV, is used to irradiate and destroy deep-rooted cancers. Small needles made of ^{60}Co of a specified activity are encased in gold and used as body implants in tumors for time periods that are related to tumor size, tumor cell reproductive rate, and the activity of the needle. (*a*) A 1.00 μg sample of ^{60}Co, that has a half-life of 5.27 y, that is used to irradiate a small internal tumor with gamma rays, is prepared in the cyclotron of a medical center. Determine the activity of the sample in curies. (*b*) What will the activity of the sample be 1.75 y from now?

Picture the Problem We can use $R_0 = \lambda N$ to find the initial activity of the sample and $R = R_0 e^{-\lambda t}$ to find the activity of the sample after 1.75 y.

(*a*) The initial activity of the sample is the product of the decay constant λ for ^{60}Co and the number of atoms N of ^{60}Co initially present in the sample:

$$R_0 = \lambda N$$

Express N in terms of the mass m of the sample, the molar mass M of ^{60}Co, and Avogadro's number N_A:

$$\frac{N}{N_A} = \frac{m}{M} \Rightarrow N = \frac{m}{M}N_A$$

Substituting for N yields:

$$R_0 = \frac{\lambda m N_A}{M}$$

The decay constant is given by:

$$\lambda = \frac{\ln(2)}{t_{1/2}}$$

Substitute for λ to obtain:

$$R_0 = \frac{\ln(2) m N_A}{t_{1/2} M}$$

Substitute numerical values and evaluate R_0:

$$R_0 = \frac{\ln(2)\left(1.00\times10^{-6}\,\text{g}\right)\left(6.022\times10^{23}\,\frac{\text{nuclei}}{\text{mol}}\right)}{\left(5.27\,\text{y}\times\frac{31.56\,\text{Ms}}{\text{y}}\right)\left(60\,\frac{\text{g}}{\text{mol}}\right)} = 4.183\times10^{7}\,\text{s}^{-1}\times\frac{1\,\text{Ci}}{3.7\times10^{10}\,\text{s}^{-1}}$$

$$= \boxed{1.13\,\text{mCi}}$$

(b) The activity varies with time according to:

$$R = R_0 e^{-\lambda t} = R_0 e^{-\left(\frac{0.693t}{5.27\text{y}}\right)}$$

Evaluate R at t = 1.75 y:

$$R = (1.13\,\text{mCi})\, e^{-\left(\frac{0.693\times1.75\text{y}}{5.27\text{y}}\right)} = \boxed{0.898\,\text{mCi}}$$

36 •• (a) Show that if the decay rate is R_0 at time t = 0 and R_1 at some later time $t = t_1$, the decay constant is given by $\lambda = t_1^{-1}\ln(R_0/R_1)$ and the half-life is given by $t_{1/2} = t_1 \ln(2)/\ln(R_0/R_1)$. ($b$) Use these results to find the decay constant and the half-life if the decay rate is 1200 Bq at t = 0 and 800 Bq at t_1 = 60.0 s.

Picture the Problem We can solve Equation 40-7 for λ to show that $\lambda = t_1^{-1}\ln(R_0/R_1)$.

(a) The half-life as a function of the decay constant λ is given by:

$$t_{1/2} = \frac{\ln(2)}{\lambda} \qquad (1)$$

From Equation 40-7 we have:

$$R_1 = R_0 e^{-\lambda t_1} \Rightarrow \lambda = \boxed{t_1^{-1}\ln(R_0/R_1)}$$

Substituting for λ in equation (1) and simplifying gives:

$$t_{1/2} = \frac{\ln(2)}{t_1^{-1}\ln(R_0/R_1)} = \boxed{\frac{t_1\ln(2)}{\ln(R_0/R_1)}}$$

(b) Substitute numerical values for t, R_1, and R_0 and evaluate λ:

$$\lambda = \frac{1}{60.0\,\text{s}}\ln\left(\frac{1200\,\text{Bq}}{800\,\text{Bq}}\right) = \boxed{0.00676\,\text{s}^{-1}}$$

Use the decay constant to find the half-life:

$$t_{1/2} = \frac{\ln(2)}{\lambda} = \frac{\ln(2)}{0.00676\,\text{s}^{-1}} = \boxed{103\,\text{s}}$$

39 •• A wooden casket is thought to be 18 000 years old. How much carbon would have to be recovered from this object to yield a ^{14}C counting rate of no less than 5 counts/min with a detection efficiency of 20 percent?

Picture the Problem Because the detection efficiency is 20 percent, the decay rate must be five times the counting rate. The required mass is given by M = (5 counts/min)/R, where R is the current counting rate per gram of carbon. We can use the assumed age of the casket to find the number of half-lives that have elapsed and $R = \left(\frac{1}{2}\right)^n R_0$ to find the current counting rate per gram of ^{14}C.

The mass of carbon required is:

$$M = \frac{5(5\,\text{counts/min})}{R} \qquad (1)$$

Because there were about 15.0 decays per minute per gram of the living wood, the counting rate per gram is:

$$R = \left(\tfrac{1}{2}\right)^n R_0 = \left(\tfrac{1}{2}\right)^n (15\,\text{counts/min}\cdot\text{g})$$

We can find n from the assumed age of the casket and the half-life of ^{14}C:

$$n = \frac{18{,}000\,\text{y}}{5730\,\text{y}} = 3.141$$

Substitute for n and evaluate R:

$$R = \left(\tfrac{1}{2}\right)^{3.141}(15\,\text{counts/min}\cdot\text{g})$$
$$= 1.70\,\text{counts/min}\cdot\text{g}$$

Substitute for R in equation (1) and evaluate M:

$$M = \frac{5(5\,\text{counts/min})}{(1.70\,\text{counts/min}\cdot\text{g})} \approx \boxed{15\,\text{g}}$$

38 •• A sample of radioactive material is initially found to have an activity of 115.0 decays/min. After 4 d 5 h, its activity is measured to be 73.5 decays/min. (*a*) Calculate the half-life of the material. (*b*) How long (from the initial time) will it take for the sample to reach an activity of 10.0 decays/min?

Picture the Problem We can use the decay rate equation $R = R_0 e^{-\lambda t}$ and the expression relating the half-life of a source to its decay constant to find the half-life of the sample. Solving the decay-rate equation for t will yield the time at which the activity level drops to any given value.

(*a*) The half-life of the material is given by:

$$t_{1/2} = \frac{\ln(2)}{\lambda} \qquad (1)$$

The decay rate is given by:

$$R = R_0 e^{-\lambda t} \;\Rightarrow\; \lambda = \frac{\ln(R_0/R)}{t} \qquad (2)$$

Substitute for λ in equation (1) and simplify to obtain:

$$t_{1/2}=\frac{\ln(2)}{\frac{\ln(R_0/R)}{t}}=\frac{\ln(2)}{\ln(R_0/R)}t$$

Substitute numerical values and evaluate $t_{1/2}$:

$$t_{1/2}=\frac{\ln(2)}{\ln\left(\frac{115\,\text{decays/min}}{73.5\,\text{decays/min}}\right)}(101\,\text{h})=\boxed{156\,\text{h}}$$

(b) Solving equation (2) for t yields:

$$t=\frac{\ln(R/R_0)}{-\lambda}$$

Express λ in terms of $t_{1/2}$:

$$\lambda=\frac{\ln(2)}{t_{1/2}}$$

Substitute for λ in the expression for t to obtain:

$$t=\frac{\ln(R/R_0)}{-\ln(2)}t_{1/2}$$

Substitute numerical values and evaluate t:

$$t=\frac{\ln\left(\frac{10\,\text{decays/min}}{115\,\text{decays/min}}\right)}{-\ln(2)}(156\,\text{h})=550\,\text{h}\times\frac{1\,\text{d}}{24\,\text{h}}=\boxed{22.9\,\text{d}}$$

39 •• The rubidium isotope ^{87}Rb is a β^- emitter that has a half-life of 4.9×10^{10} y. It decays into ^{87}Sr. This nuclear decay is used to determine the age of rocks and fossils. Rocks containing the fossils of early animals have a ratio of ^{87}Sr to ^{87}Rb of 0.0100. Assuming that there was no ^{87}Sr present when the rocks were formed, calculate the age of these fossils.

Picture the Problem We can use the decay rate equation $R=R_0e^{-\lambda t}$ and the expression relating the half-life of a source to its decay constant to find the age of the fossils.

The decay rate is given by:

$$R=R_0e^{-\lambda t}\Rightarrow t=\frac{\ln(R/R_0)}{-\lambda}$$

Express λ in terms of $t_{1/2}$:

$$\lambda=\frac{\ln(2)}{t_{1/2}}$$

Substitute for λ in the expression for t to obtain:

$$t = \frac{\ln(R/R_0)}{-\ln(2)} t_{1/2}$$

or, because the activity at any time is proportional to the number of radioactive nuclei present,

$$t = \frac{\ln(N_{\text{Rb}}/N_{0,\text{Rb}})}{-\ln(2)} t_{1/2} \qquad (1)$$

The number of ^{87}Sr nuclei present in the rocks is given by:

$$N_{\text{Sr}} = N_{0,\text{Rb}} - N_{\text{Rb}} \Rightarrow N_{0,\text{Rb}} = N_{\text{Sr}} + N_{\text{Rb}}$$

We're given that:

$$N_{\text{Sr}} = 0.01 N_{\text{Rb}} \Rightarrow \frac{N_{\text{Sr}}}{N_{\text{Rb}}} = 0.01$$

Express the ratio of $N_{0,\text{Rb}}$ to N_{Rb}:

$$\frac{N_{0,\text{Rb}}}{N_{\text{Rb}}} = \frac{N_{\text{Sr}} + N_{\text{Rb}}}{N_{\text{Rb}}} = \frac{N_{\text{Sr}}}{N_{\text{Rb}}} + 1$$
$$= 0.01 + 1 = 1.01$$

Substitute numerical values in equation (1) and evaluate the age of the fossils:

$$t = \frac{\ln\left(\frac{1}{1.01}\right)}{-\ln(2)} (4.9\times10^{10}\text{ y}) \approx \boxed{7.0\times10^{8}\text{ y}}$$

40 ••• Consider a single nucleus of a radioactive isotope that has a decay rate equal to λ. The nucleus has not decayed at t = 0. The probability that the nucleus will decay between time t and time $t + dt$ is equal to $\lambda e^{-\lambda t} dt$. (*a*) Show that this statement is consistent with the fact that the probability is 1 that the nucleus will decay between t = 0 and $t = \infty$. (*b*) Show that the expected lifetime of the nucleus is equal to $1/\lambda$. *Hint: The expected lifetime is equal to* $\int_0^\infty t\lambda e^{-\lambda t} dt$ *divided by* $\int_0^\infty \lambda e^{-\lambda t} dt$. (*c*) A sample of material contains a significant number of these radioactive nuclei at time t = 0. What will have been the mean lifetime of these nuclei some time later, after they have all decayed?

Picture the Problem (*a*) Integrating the probability function between 0 and ∞ will show that its value is 1. (*b*) We can evaluate this integral by changing variables to obtain a form that we can find in a table of integrals.

(*a*) The probability that the nucleus will decay between t = 0 and $t = \infty$ is given by:

$$P = \int_0^\infty \lambda e^{-\lambda t} dt = \lambda \int_0^\infty e^{-\lambda t} dt$$

Integrating yields:

$$P = \lambda \left.\frac{e^{-\lambda t}}{-\lambda}\right]_0^\infty = -e^{-\lambda t}\Big]_0^\infty = \boxed{1}$$

(*b*) The expected lifetime of the nucleus is given by:

$$\tau = \frac{\int_0^\infty t\lambda e^{-\lambda t}dt}{\int_0^\infty \lambda e^{-\lambda t}dt}$$

or, because $\int_0^\infty \lambda e^{-\lambda t}dt = 1$,

$$\tau = \int_0^\infty t\lambda e^{-\lambda t}dt$$

Change variables by letting $x = \lambda t$. Then:

$$dx = \lambda dt\,,\ dt = \frac{dx}{\lambda}\text{, and } t = \frac{x}{\lambda}$$

Substitute to obtain:

$$\tau = \int_0^\infty t\lambda e^{-\lambda t}dt = \int_0^\infty \frac{x}{\lambda}\lambda e^{-x}\frac{dx}{\lambda} = \frac{1}{\lambda}\int_0^\infty xe^{-x}dx$$

From integral tables:

$$\int_0^\infty xe^{-x}dx = 1$$

Substitute in the expression for τ to obtain:

$$\tau = \boxed{1/\lambda}$$

(*c*) The mean lifetime after all the nuclei have decayed is $\boxed{1/\lambda}$, the same as the expected lifetime.

Nuclear Reactions

41 • Using Table 40-1, find the Q values for the following reactions: (*a*) $^1H + {}^3H \rightarrow {}^3He + n + Q$ and (*b*) $^2H + {}^2H \rightarrow {}^3He + n + Q$.

Picture the Problem We can use $Q = -(\Delta m)c^2$ to find the Q values for these reactions.

(*a*) Find the mass of each atom from Table 40-1:

$$m_{^1\text{H}} = 1.007\ 825\ \text{u}$$
$$m_{^3\text{H}} = 3.016\ 049\ \text{u}$$
$$m_{^3\text{He}} = 3.016\ 029\ \text{u}$$
$$m_{\text{n}} = 1.008\ 665\,\text{u}$$

Calculate the initial mass m_i of the incoming particles:

$$m_{\text{i}} = 1.007\ 825\ \text{u} + 3.016\ 049\ \text{u} = 4.023\,874\ \text{u}$$

Calculate the final mass m_f:

$$m_{\text{f}} = 3.016\ 029\ \text{u} + 1.008\ 665\ \text{u} = 4.024\ 694\ \text{u}$$

Calculate the increase in mass:

$$\Delta m = m_{\text{f}} - m_{\text{i}} = 4.024\ 694\ \text{u} - 4.023\,874\ \text{u} = 0.000\ 820\ \text{u}$$

Calculate the Q value:

$$Q = -(\Delta m)c^2 = -(0.000\ 820\,\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{u}\right) = \boxed{-0.764\,\text{MeV}}$$

(*b*) Proceed as in (*a*) to obtain:

$$Q = (0.003\ 510\,\text{u})\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)c^2 = \boxed{3.27\,\text{MeV}}$$

Remarks: Because *Q* < 0 for the first reaction, it is endothermic. Because *Q* > 0 for the second reaction, it is exothermic.

42 • Using Table 40-1, find the Q values for the following reactions: (*a*) $^2\text{H} + {}^2\text{H} \rightarrow {}^3\text{H} + {}^1\text{H} + Q$, (*b*) $^2\text{H} + {}^3\text{He} \rightarrow {}^4\text{He} + {}^1\text{H} + Q$, and (*c*) $^6\text{Li} + \text{n} \rightarrow {}^3\text{H} + {}^4\text{He} + \text{Q}$.

Picture the Problem We can use $Q = -(\Delta m)c^2$ to find the Q values for these reactions.

(*a*) Find the mass of each atom from Table 40-1:

$$m_{^2\text{H}} = 2.014\,102\ \text{u}$$
$$m_{^3\text{H}} = 3.016\ 049\ \text{u}$$
$$m_{^1\text{H}} = 1.007\ 825\ \text{u}$$

Calculate the initial mass m_i of the incoming particles:

$$m_i = 2(2.014\,102\text{ u}) = 4.028\,204\text{ u}$$

Calculate the final mass m_f:

$$m_f = 3.016\,049\text{ u} + 1.007\,825\text{ u} = 4.023\,874\text{ u}$$

Calculate the increase in mass:

$$\Delta m = m_f - m_i = 4.023\,874\text{ u} - 4.028\,204\text{ u} = -0.004\,330\text{ u}$$

Calculate the Q value:

$$Q = -(\Delta m)c^2 = -(-0.004\,330\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{u}\right) = \boxed{4.03\,\text{MeV}}$$

(b) Proceed as in (a) to obtain:

$$Q = -(\Delta m)c^2 = -(-0.019\,703\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right) = \boxed{18.4\,\text{MeV}}$$

(c) Proceed as in (a) to obtain:

$$Q = -(\Delta m)c^2 = -(-0.005\,135\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right) = \boxed{4.78\,\text{MeV}}$$

43 •• [SSM] (a) Use the values 14.003 242 u and 14.003 074 u for the atomic masses of ^{14}C and ^{14}N, respectively, to calculate the Q value (in MeV) for the β-decay reaction $^{14}_{6}\text{C} \rightarrow {}^{14}_{7}\text{N} + \text{e}^- + \bar{\nu}_e$. ($b$) Explain why you should not add the mass of the electron to that of atomic ^{14}N for the calculation in (a).

Picture the Problem We can use $Q = -(\Delta m)c^2$ to find the Q values for this reaction.

(a) The masses of the atoms are:

$$m_{^{14}\text{C}} = 14.003\,242\,\text{u}$$
$$m_{^{14}\text{N}} = 14.003\,074\,\text{u}$$

Calculate the increase in mass:

$$\Delta m = m_f - m_i = 14.003\,074\,\text{u} - 14.003\,242\,\text{u} = -0.000\,168\,\text{u}$$

Calculate the Q value:

$$Q = -(\Delta m)c^2 = -(-0.000\,168\,\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right) = \boxed{0.156\,\text{MeV}}$$

(b) The masses given are for atoms, not nuclei, so for nuclear masses the masses are too large by the atomic number multiplied by the mass of an electron. For the given nuclear reaction, the mass of the carbon atom is too large by $6m_e$ and the mass of the nitrogen atom is too large by $7m_e$. Subtracting $6m_e$ from both sides of the reaction equation leaves an extra electron mass on the right. Not including the mass of the beta particle (electron) is mathematically equivalent to explicitly subtracting $1m_e$ from the right side of the equation.

44 •• (a) Use the values 13.005 738 u and 13.003 354 u for the atomic masses of ${}^{13}_{7}\text{N}$ and ${}^{13}_{6}\text{C}$, respectively, to calculate the Q value (in MeV) for the β-decay reaction ${}^{13}_{7}\text{N} \rightarrow {}^{13}_{6}\text{C} + e^+ + \nu_e$. ($b$) Explain why you need to add twice the mass of an electron to the mass of ${}^{13}_{6}\text{C}$ during the calculation of the Q value for the reaction in (a).

Picture the Problem We can use $Q = -(\Delta m)c^2$ to find the Q values for this reaction.

(a) The masses of the atoms are:

$$m_{^{13}\text{N}} = 13.005\,738\,\text{u}$$

and

$$m_{^{13}\text{C}} = 13.003\,354\,\text{u}$$

For β^+ decay:

$$Q = (m_i - m_f - 2m_e)c^2 = (m_i - m_f)c^2 - 2m_e c^2$$

Calculate $m_i - m_f$:

$$m_i - m_f = 13.005\,738\,\text{u} - 13.003\,354\,\text{u} = 0.002\,384\,\text{u}$$

Calculate the Q value:

$$Q = (0.002\ 384\,\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{u}\right) - 2(0.511\ \text{MeV}) = \boxed{1.20\,\text{MeV}}$$

(b) The atomic masses include the masses of the electrons of the neutral atoms. In this reaction the initial atom has 7 electrons and the final atom has 6 electrons. Moreover, in addition to one electron not included in the atomic masses, a positron of mass equal to that of an electron is created. Consequently, one must add the rest energies of two electrons to the rest energy of the daughter atomic mass when calculating Q.

Fission and Fusion

45 • Assuming an average energy of 200 MeV per fission, calculate the number of fissions per second needed for a 500-MW reactor.

Picture the Problem The power output of the reactor is the product of the number of fissions per second and energy liberated per fission.

Express the required number N of fissions per second in terms of the power output P and the energy released per fission $E_{\text{per fission}}$:

$$N = \frac{P}{E_{\text{per fission}}}$$

Substitute numerical values and evaluate N:

$$N = \frac{500\,\text{MW}}{200\,\text{MeV}} = \frac{5.00\times10^8\,\frac{\text{J}}{\text{s}}\times\frac{1\text{eV}}{1.602\times10^{-19}\ \text{J}}}{200\,\text{MeV}} = \boxed{1.56\times10^{19}\,\text{s}^{-1}}$$

46 • If the reproduction factor in a reactor is 1.1, find the number of generations needed for the power level to (a) double, (b) increase by a factor of 10, and (c) increase by a factor of 100. Find the time needed in each case if (d) there are no delayed neutrons, so that the time between generations is 1.0 ms, and (e) there are delayed neutrons that make the average time between generations 100 ms.

Picture the Problem If k = 1.1, the reaction rate after N generations is 1.1^N. We can find the number of generations by setting 1.1^N equal, in turn, to 2, 10, and 100 and solving for N. The time to increase by a given factor is the number of generations N needed to increase by that factor times the generation time.

(*a*) Set 1.1^N equal to 2 and solve for N:

$$(1.1)^N = 2 \Rightarrow N\ln(1.1) = \ln(2)$$

and $N = \dfrac{\ln(2)}{\ln(1.1)} = \boxed{7.3}$

(*b*) Set 1.1^N equal to 10 and solve for N:

$$(1.1)^N = 10 \Rightarrow N\ln(1.1) = \ln(10)$$

and $N = \dfrac{\ln(10)}{\ln(1.1)} = \boxed{24}$

(*c*) Set 1.1^N equal to 100 and solve for N:

$$(1.1)^N = 100 \Rightarrow N\ln(1.1) = \ln(100)$$

and $N = \dfrac{\ln(100)}{\ln(1.1)} = \boxed{48}$

(*d*) Multiply the number of generations by the generation time:

$$t_2 = Nt_1 = (7.27)(1.0\,\text{ms}) = \boxed{7.3\,\text{ms}}$$

$$t_{10} = Nt_1 = (24.2)(1.0\,\text{ms}) = \boxed{24\,\text{ms}}$$

$$t_{100} = Nt_1 = (48.3)(1.0\,\text{ms}) = \boxed{48\,\text{ms}}$$

(*e*) Multiply the number of generations by the generation time:

$$t_2 = Nt_1 = (7.27)(100\,\text{ms}) = \boxed{0.73\,\text{s}}$$

$$t_{10} = Nt_1 = (24.2)(100\,\text{ms}) = \boxed{2.4\,\text{s}}$$

$$t_{100} = Nt_1 = (48.3)(100\,\text{ms}) = \boxed{4.8\,\text{s}}$$

47 •• [SSM] Consider the following fission reaction:
${}^{235}_{92}\text{U} + \text{n} \to {}^{95}_{42}\text{Mo} + {}^{139}_{57}\text{La} + 2\text{n} + Q$. The masses of the neutron, ^{235}U, ^{95}Mo, and ^{139}La are 1.008 665 u, 235.043 923 u, 94.905 842 u, and 138.906 348 u, respectively. Calculate the Q value, in MeV, for this fission reaction.

Picture the Problem We can use $Q = -(\Delta m)c^2$, where $\Delta m = m_\text{f} - m_\text{i}$, to calculate the Q value.

The Q value, in MeV, is given by:

$$Q = -(\Delta m)c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$

Calculate the change in mass Δm:

$$\begin{aligned}\Delta m &= m_f - m_i \\ &= 94.905\,842\text{ u} + 138.906\,348\text{ u} + 2(1.008\,665\text{ u}) \\ &\qquad - (235.043\,923\text{ u} + 1.008\,665\text{ u}) \\ &= -0.223\,068\text{ u}\end{aligned}$$

Substitute for Δm and evaluate Q:

$$Q = -(-0.223\,068\text{ u})c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right) = \boxed{208\text{ MeV}}$$

48 •• In 1989, researchers claimed to have achieved fusion in an electrochemical cell at room temperature. Their now thoroughly discredited claim was that a power output of 4.00 W was produced by deuterium fusion reactions in the palladium electrode of their apparatus. The two most likely reactions are

$$^{2}\text{H} + {}^{2}\text{H} \rightarrow {}^{3}\text{He} + \text{n} + 3.27\text{ MeV}$$

and

$$^{2}\text{H} + {}^{2}\text{H} \rightarrow {}^{3}\text{H} + {}^{1}\text{H} + 4.03\text{ MeV}$$

Of the deuterium nuclei that participated in these reactions, assume half of the deuterium nuclei participated in the first reaction and the other half participated in the second reaction. How many neutrons per second would we expect to be emitted in the generation of 4.00 W of power?

Picture the Problem We can find the number of neutrons per second in the generation of 4 W of power from the number of reactions per second.

The number of neutrons emitted per second is:

$$N_n = \tfrac{1}{2}N$$

where N is the number of reactions per second.

The number of reactions per second is:

$$N = 2\left(\frac{4.00\frac{\text{J}}{\text{s}} \times \frac{1\text{eV}}{1.602\times10^{-19}\text{ J}}}{3.27\,\text{MeV} + 4.03\,\text{MeV}}\right)$$

$$= 6.841\times10^{12}\text{ s}^{-1}$$

Substitute for N and evaluate N_n:

$$N_n = \tfrac{1}{2}\left(6.841\times10^{12}\ \text{s}^{-1}\right) = \boxed{3.42\times10^{12}\ \text{neutrons/s}}$$

49 •• A fusion reactor that uses only deuterium for fuel would have the two reactions in Problem 50 taking place in the reactor. The ^{3}H produced in the second reaction reacts immediately with another ^{2}H in the reaction

$$^3\text{H} + {}^2\text{H} \rightarrow {}^4\text{He} + \text{n} + 17.6\ \text{MeV}$$

The ratio of ^{2}H to ^{1}H atoms in naturally occurring hydrogen is 1.5×10^{-4}. How much energy would be produced from 4.0 L of water if all of the ^{2}H nuclei undergo fusion?

Picture the Problem We can use the energy released in the reactions of Problem 50, together with the 17.6 MeV released in the reaction described in this problem, to find the energy released using 5 ^{2}H nuclei. Finding the number of D atoms in 4.0 L of H_2O, we can then find the energy produced if all of the ^{2}H nuclei undergo fusion.

Find the energy released using 5 ^{2}H nuclei:

$$Q = 3.27\,\text{MeV} + 4.03\,\text{MeV} + 17.6\,\text{MeV} = 24.9\,\text{MeV}$$

The number of H atoms in 4.0 L of H_2O is:

$$N_H = 2\left(\frac{m_{H_2O}}{18\,\text{g/mol}}\right)N_A$$

Substitute numerical values and evaluate N_H:

$$N_H = 2\left(\frac{4.0\,\text{kg}}{18\,\text{g/mol}}\right)\left(6.022\times10^{23}\ \text{atoms/mol}\right) = 2.676\times10^{26}$$

The number of D atoms in 4.0 L of H_2O is:

$$N_D = \left(1.5\times10^{-4}\right)N_H = \left(1.5\times10^{-4}\right)\left(2.676\times10^{26}\right) = 4.01\times10^{22}$$

The energy produced is given by:

$$E = \frac{N_D}{5}Q$$

Substitute numerical values and evaluate E:

$$E = \frac{4.01\times10^{22}}{5}(24.9\,\text{MeV})$$
$$= 1.997\times10^{23}\ \text{MeV}\times\frac{1.602\times10^{-19}\ \text{J}}{\text{eV}}$$
$$= \boxed{3.2\times10^{10}\ \text{J}}$$

50 ••• The fusion reaction between ^{2}H and ^{3}H is

$$^{3}\text{H} + {}^{2}\text{H} \rightarrow {}^{4}\text{He} + \text{n} + 17.6\ \text{MeV}$$

Using the conservation of momentum and the given Q value, find the final energies of both the ^{4}He nucleus and the neutron, assuming the initial kinetic energy of the system is 1.00 MeV and the initial momentum of the system is zero.

Picture the Problem We can use the conservation of momentum and the given Q value to find the final energies of both the ^{4}He nucleus and the neutron, assuming that the initial momentum of the system is zero.

Apply conservation of energy to obtain:

$$18.6\,\text{MeV} = \tfrac{1}{2}m_{\text{He}}v_{\text{He}}^2 + \tfrac{1}{2}m_{\text{n}}v_{\text{n}}^2 = K_{\text{He}} + K_{\text{n}} \quad (1)$$

Apply conservation of momentum to obtain:

$$m_{\text{He}}v_{\text{He}} + m_{\text{n}}v_{\text{n}} = 0 \quad (2)$$

Solve equation (2) for v_{He}:

$$v_{\text{He}} = -\frac{m_{\text{n}}v_{\text{n}}}{m_{\text{He}}} \Rightarrow v_{\text{He}}^2 = \left(\frac{m_{\text{n}}}{m_{\text{He}}}\right)^2 v_{\text{n}}^2$$

Substitute for v_{He}^2 in equation (1):

$$18.6\,\text{MeV} = \tfrac{1}{2}m_{\text{He}}\left(\frac{m_{\text{n}}}{m_{\text{He}}}\right)^2 v_{\text{n}}^2 + \tfrac{1}{2}m_{\text{n}}v_{\text{n}}^2$$

or

$$18.6\,\text{MeV} = \tfrac{1}{2}m_{\text{n}}v_{\text{n}}^2\left(1+\frac{m_{\text{n}}}{m_{\text{He}}}\right) = K_{\text{n}}\left(1+\frac{m_{\text{n}}}{m_{\text{He}}}\right)$$

Solving for K_{n} yields:

$$K_{\text{n}} = \frac{18.6\,\text{MeV}}{1+\dfrac{m_{\text{n}}}{m_{\text{He}}}}$$

Substitute numerical values for m_n and m_{He} and evaluate K_n:

$$K_n = \frac{18.6\,\text{MeV}}{1+\dfrac{1.008665\,\text{u}}{4.002603\,\text{u}}} = 14.86\,\text{MeV} = \boxed{14.9\,\text{MeV}}$$

Use equation (1) to find K_{He}:

$$K_{He} = 18.6\,\text{MeV} - K_n = 18.6\,\text{MeV} - 14.86\,\text{MeV} = \boxed{3.7\,\text{MeV}}$$

51 ••• Energy is generated in the Sun and other stars by fusion. One of the fusion cycles, the proton–proton cycle, consists of the following reactions:

$$^1\text{H} + {}^1\text{H} \to {}^2\text{H} + e^+ + \nu_e$$
$$^1\text{H} + {}^2\text{H} \to {}^3\text{He} + \gamma$$

followed by

$$^1\text{H} + {}^3\text{He} \to {}^4\text{He} + e^+ + \nu_e$$

(*a*) Show that the net effect of these reactions is

$$4\,{}^1\text{H} \to {}^4\text{He} + 2e^+ + 2\nu_e + \gamma$$

(*b*) Show that 24.7 MeV is released during this cycle (not counting the additional energy of 1.02 MeV that is released when each positron meets an electron and the two annihilate). (*c*) The Sun radiates energy at the rate of approximately 4.0×10^{26} W. Assuming that this is due to the conversion of four protons into helium, γ-rays, and neutrinos, which releases 26.7 MeV, what is the rate of proton consumption in the Sun? How long will the Sun last if it continues to radiate at its present level? (Assume that protons constitute about half of the total mass, 2.0×10^{30} kg, of the Sun.)

Picture the Problem Adding the three reactions will yield their net effect. We can use $(\Delta m)c^2$ to find the rest energy released in the cycle and find the rate of proton consumption from the ratio of the Sun's power output to the released per proton in fusion.

(*a*) Add the three reactions to obtain:

$$^1\text{H} + {}^1\text{H} + {}^1\text{H} + {}^2\text{H} + {}^1\text{H} + {}^3\text{He} \to {}^2\text{H} + \beta^+ + \nu_e + {}^3\text{He} + \gamma + {}^4\text{He} + \beta^+ + \nu_e$$

Simplify to obtain:

$$\boxed{4\,{}^1\text{H} \to {}^4\text{He} + 2\beta^+ + 2\nu_e + \gamma}$$

(*b*) Express the rest energy released in this cycle:

$$(\Delta m)c^2 = \left(4m_{\mathrm{p}} - m_\alpha - 4m_{\mathrm{e}}\right)c^2$$

Use Table 40-1 to find the masses of the participants in the reaction and evaluate $(\Delta m)c^2$:

$$(\Delta m)c^2 = [4(1.007\ 825\ \mathrm{u}) - 4.002\ 603\ \mathrm{u}]c^2 \times \frac{931.5\,\mathrm{MeV}/c^2}{\mathrm{u}} - 4(0.511\,\mathrm{MeV}) = \boxed{24.7\,\mathrm{MeV}}$$

(*c*) Express the rate *R* of proton consumption:

$$R = \frac{P}{E} \qquad (1)$$

where *E* is the energy released per proton in fusion.

Find *N*, the number of protons in the Sun:

$$N = \frac{\frac{1}{2}m_{\mathrm{sun}}}{m_{\mathrm{p}}} = \frac{\frac{1}{2}\left(1.99\times10^{30}\ \mathrm{kg}\right)}{1.673\times10^{-27}\ \mathrm{kg}} = 5.96\times10^{56}$$

where we have assumed that protons constitute about half of the total mass of the Sun.

The energy released per proton in fusion is:

$$E = \tfrac{1}{4}(26.7\,\mathrm{MeV}) = 6.675\,\mathrm{MeV} = 6.675\,\mathrm{MeV}\times\frac{1.602\times10^{-19}\ \mathrm{J}}{\mathrm{eV}} = 1.07\times10^{-12}\ \mathrm{J}$$

Substitute numerical values in equation (1) and evaluate *R*:

$$R = \frac{4.0\times10^{26}\ \mathrm{W}}{1.07\times10^{-12}\ \mathrm{J}} = 3.74\times10^{38}\ \mathrm{s}^{-1} \approx \boxed{3.7\times10^{38}\ \mathrm{s}^{-1}}$$

The time *T* for the consumption of all protons is:

$$T = \frac{N}{R} = \frac{5.96\times10^{56}}{3.74\times10^{38}\ \mathrm{s}^{-1}} = 1.59\times10^{18}\ \mathrm{s}\times\frac{1\,\mathrm{y}}{31.56\,\mathrm{Ms}} \approx \boxed{5.0\times10^{10}\ \mathrm{y}}$$

General Problems

52 • (*a*) Show that ke^2 = 1.44 MeV·fm, where k is the Coulomb constant and e is the magnitude of the electron charge. (*b*) Show that hc = 1240 MeV·fm.

Picture the Problem We can use the values of k, e, h, and c and the appropriate conversion factors to show that ke^2 = 1.44 MeV·fm and hc = 1240 MeV·fm

(*a*) Evaluate ke^2 to obtain:

$$\begin{aligned} ke^2 &= \left(8.988\times10^{9}\ \mathrm{N\cdot m^2/C^2}\right)\left(1.602\times10^{-19}\ \mathrm{C}\right)^2 = 2.307\times10^{-28}\ \mathrm{N\cdot m^2} \\ &= 2.307\times10^{-28}\ \mathrm{J\cdot m}\times\frac{1\,\mathrm{eV}}{1.602\times10^{-19}\ \mathrm{J}} = 1.44\times10^{-9}\ \mathrm{eV\cdot m} \\ &= 1.44\times10^{-9}\ \mathrm{eV\cdot m}\times\frac{1\,\mathrm{fm}}{10^{-15}\ \mathrm{m}}\times\frac{1\,\mathrm{MeV}}{10^{6}\ \mathrm{eV}} = \boxed{1.44\,\mathrm{MeV\cdot fm}} \end{aligned}$$

(*b*) Evaluate hc to obtain:

$$\begin{aligned} hc &= \left(6.626\times10^{-34}\ \mathrm{J\cdot s}\right)\left(2.998\times10^{8}\ \mathrm{m/s}\right) = 1.99\times10^{-25}\ \mathrm{J\cdot m} \\ &= 1.99\times10^{-25}\ \mathrm{J\cdot m}\times\frac{1\,\mathrm{eV}}{1.602\times10^{-19}\ \mathrm{J}} = 1240\times10^{-9}\ \mathrm{eV\cdot m} \\ &= 1240\times10^{-9}\ \mathrm{eV\cdot m}\times\frac{1\,\mathrm{fm}}{10^{-15}\ \mathrm{m}}\times\frac{1\,\mathrm{MeV}}{10^{6}\ \mathrm{eV}} = \boxed{1240\,\mathrm{MeV\cdot fm}} \end{aligned}$$

53 • **[SSM]** The counting rate from a radioactive source is 6400 counts/s. The half-life of the source is 10 s. Make a plot of the counting rate as a function of time for times up to 1 min. What is the decay constant for this source?

Picture the Problem We can use the given information regarding the half-life of the source to find its decay constant. We can then plot a graph of the counting rate as a function of time.

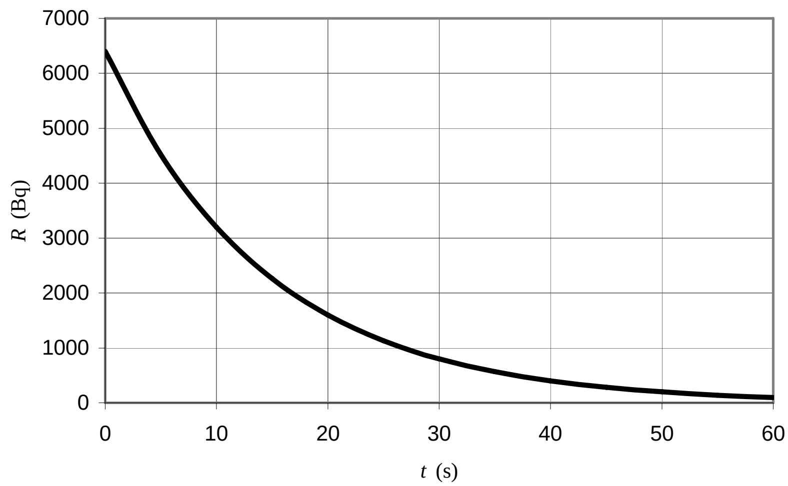
The decay constant is related to the half-life of the source:

$$\lambda = \frac{\ln(2)}{t_{1/2}} = \frac{\ln(2)}{10\,\mathrm{s}} = 0.0693\,\mathrm{s}^{-1} = \boxed{0.069\,\mathrm{s}^{-1}}$$

The activity of the source is given by:

$$R = R_0 e^{-\lambda t} = \left(6400\,\mathrm{Bq}\right)e^{-\left(0.0693\,\mathrm{s}^{-1}\right)t}$$

The following graph of $R = (6400\,\text{Bq})e^{-(0.0693\,\text{s}^{-1})t}$ was plotted using a spreadsheet program.



54 • Find the energy needed to remove a neutron from (*a*) ^{4}He and (*b*) ^{7}Li.

Picture the Problem The energy needed to remove a neutron is given by $Q = (\Delta m)c^2$ where Δm is the difference between the sum of the masses of the reaction products and the mass of the target nucleus.

(*a*) The reaction is: $^4\text{He} + Q = {}^3\text{He} + \text{n}$

The masses are (see Table 40-1):

$$m_{^4\text{He}} = 4.002\,603\ \text{u}$$
$$m_{^3\text{He}} = 3.016\,029\ \text{u}$$
$$m_\text{n} = 1.008\,665\ \text{u}$$

Calculate the final mass:

$$m_\text{f} = 3.016\,029\ \text{u} + 1.008\,665\ \text{u} = 4.024\,694\ \text{u}$$

Calculate the increase in mass:

$$\Delta m = m_\text{f} - m_\text{i} = 4.024\,694\ \text{u} - 4.002\,603\ \text{u} = 0.022\,091\ \text{u}$$

Calculate the energy Q needed to remove a neutron from ^{4}He:

$$Q = (\Delta m)c^2$$
$$= (0.022\ 091\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)$$
$$= \boxed{20.6\,\text{MeV}}$$

(*b*) The reaction is:

$$^7\text{Li} + Q = {}^6\text{Li} + \text{n}$$

The masses are (see Table 40-1):

$$m_{^7\text{Li}} = 7.016\ 004\ \text{u}$$
$$m_{^6\text{Li}} = 6.015\,122\ \text{u}$$
$$m_\text{n} = 1.008\ 665\,\text{u}$$

Calculate the final mass:

$$m_\text{f} = 6.015\,122\ \text{u} + 1.008\ 665\ \text{u}$$
$$= 7.023\ 787\ \text{u}$$

Calculate the increase in mass:

$$\Delta m = m_\text{f} - m_\text{i}$$
$$= 7.023\ 787\ \text{u} - 7.016\ 004\ \text{u}$$
$$= 0.007\ 783\ \text{u}$$

Calculate the energy Q needed to remove a neutron from ^{4}He:

$$Q = (\Delta m)c^2$$
$$= (0.007\ 783\text{u})c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$
$$= \boxed{7.25\,\text{MeV}}$$

55 • The isotope ^{14}C decays according to $^{14}\text{C} \rightarrow {}^{14}\text{N} + \text{e}^- + \overline{\nu}_\text{e}$. The atomic mass of ^{14}N is 14.003 074 u. Determine the maximum kinetic energy of the electron. (Neglect recoil of the nitrogen atom.)

Picture the Problem The maximum kinetic energy of the electron is given by $K_\text{max} = Q = \left(m_{^{14}\text{C}} - m_{^{14}\text{N}}\right)c^2$.

The maximum kinetic energy of the electron is the Q value for the reaction:

$$K_\text{max} = Q = \left(m_{^{14}\text{C}} - m_{^{14}\text{N}}\right)c^2$$

Find the mass of each atom from Table 40-1:

$$m_{^{14}\text{C}} = 14.003\ 242\ \text{u}$$
$$m_{^{14}\text{N}} = 14.003\,074\ \text{u}$$

Calculate $\Delta m = m_{^{14}\text{C}} - m_{^{14}\text{N}}$:

$$\Delta m = 14.003\,242\text{ u} - 14.003\,074\text{ u} = 0.000\,168\,\text{u}$$

Calculate the maximum kinetic energy of the electron:

$$Q = (\Delta m)c^2 = (0.000\,168\,\text{u})c^2\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right) = \boxed{156\text{ keV}}$$

56 • The density of a neutron star is the same as the density of a nucleus. If our Sun were to collapse to a neutron star, what would be the radius of that object?

Picture the Problem We can use the definition density to find the radius of the neutron star.

Relate the mass of the neutron star to the mass of the sun *M*, the volume *V* of the star and the nuclear density ρ:

$$M = \rho V = \tfrac{4}{3}\pi\rho R^3 \Rightarrow R = \sqrt[3]{\frac{3M}{4\pi\rho}}$$

where *R* is the radius of the star.

In Problem 20 it was established that:

$$\rho = 1.174 \times 10^{17}\text{ kg/m}^3$$

Substitute numerical values and evaluate *R*:

$$R = \sqrt[3]{\frac{3(1.99\times10^{30}\text{ kg})}{4\pi(1.174\times10^{17}\text{ kg/m}^3)}} = \boxed{15.9\,\text{km}}$$

57 •• **[SSM]** Show that the ^{109}Ag nucleus is stable and does not undergo alpha decay, ${}^{109}_{47}\text{Ag} \to {}^{4}_{2}\text{He} + {}^{105}_{45}\text{Rh} + Q$. The mass of the ^{109}Ag nucleus is 108.904 756 u, and the products of the decay are 4.002 603 u and 104.905 250 u, respectively.

Picture the Problem We can show that ^{109}Ag is stable against alpha decay by demonstrating that its *Q* value is negative.

The *Q* value for this reaction is:

$$Q = -[(m_{\text{Rh}} + m_{\alpha}) - m_{\text{Ag}}]c^2\left(931.5\,\frac{\text{MeV}/c^2}{\text{u}}\right)$$

Substitute numerical values and evaluate Q:

$$Q = -\left[\left(4.002\ 603\ \text{u} + 104.905\ 250\ \text{u}\right) - 108.904\ 756\ \text{u}\right]c^2\left(931.5\frac{\text{MeV}/c^2}{\text{u}}\right)$$

$$= \boxed{-2.88\ \text{MeV}}$$

Remarks: Alpha decay occurs spontaneously and the Q value will equal the sum of the kinetic energies of the alpha particle and the recoiling daughter nucleus, $Q = K_\alpha + K_\text{D}$. Kinetic energy cannot be negative; hence, alpha decay cannot occur unless the mass of the parent nucleus is greater than the sum of the masses of the alpha particle and daughter nucleus, $m_\text{P} > m_\alpha + m_\text{D}$. Alpha decay cannot take place unless the total rest mass decreases.

58 •• Gamma rays can be used to induce photofission (fission triggered by the absorption of a photon) in nuclei. Calculate the threshold photon wavelength for the following nuclear reaction: $^2\text{H} + \gamma \rightarrow {}^1\text{H} + \text{n}$. Use Table 40-1 for the masses of the interacting particles.

Picture the Problem We can use $E_\text{threshold} = hf_\text{threshold} = hc/\lambda_\text{threshold}$, where $E_\text{threshold}$ is the binding energy of the deuteron, to find the threshold wavelength for the given nuclear reaction.

Express the threshold energy of the photon:

$$E_\text{threshold} = hf_\text{threshold} = \frac{hc}{\lambda_\text{threshold}}$$

Solve for the threshold wavelength:

$$\lambda_\text{threshold} = \frac{hc}{E_\text{threshold}} \qquad (1)$$

The threshold energy equals the binding energy of the deuteron:

$$E_\text{threshold} = E_\text{B} = \left[m_\text{D} - \left(m_\text{p} + m_\text{n}\right)\right]c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$

Substitute numerical values and evaluate E_th, the energy that must be added to the deuteron that will cause it to fission:

$$E_\text{threshold} = \left[2.014\,102\ \text{u} - \left(1.007\ 825\ \text{u} + 1.008\ 665\ \text{u}\right)\right]\left(931.5\,\text{MeV/u}\right)$$

$$= -2.22\ \text{MeV} \times \frac{1.602\times10^{-19}\ \text{J}}{\text{eV}} = -3.55\times10^{-13}\ \text{J}$$

Substitute numerical values in equation (1) and evaluate $\lambda_{\text{threshold}}$:

$$\lambda_{\text{threshold}} = \frac{(6.626\times10^{-34}\ \text{J}\cdot\text{s})(2.998\times10^{8}\ \text{m/s})}{3.55\times10^{-13}\ \text{J}} = 5.60\times10^{-13}\ \text{m} = \boxed{0.560\ \text{pm}}$$

59 • The relative abundance of ^{40}K (potassium 40) is 1.2×10^{-4}. The isotope ^{40}K has a molar mass of 40.0 g/mol, is radioactive and has a half-life of 1.3×10^{9} y. Potassium is an essential element of every living cell. In the human body the mass of potassium constitutes approximately 0.36 percent of the total mass. Determine the activity of this radioactive source in a student whose mass is 60 kg.

Picture the Problem The activity of a radioactive source is the product of the number of radioactive nuclei present and their decay constant.

The activity of the isotope ^{40}K in the student is:

$$R = N_{40}\lambda = \frac{N_{40}\ln(2)}{t_{1/2}} \qquad (1)$$

Find N, the number of K nuclei in the student:

$$\frac{N}{N_{\text{A}}} = \frac{0.0036m}{M} \Rightarrow N = \frac{0.0036mN_{\text{A}}}{M}$$

where m is the mass of the student and M is the atomic mass of K.

Substitute numerical values and evaluate N:

$$N = \frac{(0.0036)(60\ \text{kg})(6.022\times10^{23}\ \text{nuclei/mol})}{39.098\ \text{g/mol}} = 3.326\times10^{24}$$

The number N_{40} of ^{40}K nuclei in the student is the product of the relative abundance and the number of K nuclei in the student:

$$\begin{aligned} N_{40} &= \text{Relative abundance} \times N \\ &= (1.2\times10^{-4})(3.326\times10^{24}) \\ &= 3.991\times10^{20} \end{aligned}$$

Substitute numerical values in equation (1) and evaluate R:

$$R = \frac{(3.991\times10^{20})\ln(2)}{1.3\times10^{9}\ \text{y}\times\dfrac{31.56\ \text{Ms}}{\text{y}}} = \boxed{6.7\times10^{3}\ \text{Bq}}$$

60 •• When a positron makes contact with an electron, the electron–positron pair annihilate by way of the reaction $\beta^+ + \beta^- \to 2\gamma$. Calculate the minimum total energy, in MeV, of the two photons created when a positron–electron pair annihilate.

Picture the Problem We can find the energy released in the reaction $\beta^+ + \beta^- \to Q$ by recognizing that a total of 2 electron masses are converted into energy in this annihilation.

The energy released when a positron-electron pair annihilate is given by:

$$Q = E = 2m_e c^2$$

Substitute numerical values and evaluate Q:

$$Q = 2\left(9.109\times10^{-31}\,\text{kg}\right)\left(2.998\times10^{8}\,\text{m/s}\right)^2 = 1.64\times10^{-13}\,\text{J}\times\frac{1\,\text{eV}}{1.602\times10^{-19}\,\text{J}}$$

$$= \boxed{1.02\,\text{MeV}}$$

61 •• The isotope ^{24}Na is a β emitter and has a half-life of 15 h. A saline solution containing this radioactive isotope has an activity of 600 kBq and is injected into the bloodstream of a patient. Ten hours later, the activity of 1 mL of blood from this individual yields a counting rate of 12 counts/s at a counting efficiency of 20 percent. Determine the volume of blood in this patient.

Picture the Problem We can use the fact that, after n half-lives, the decay rate of the ^{24}Na isotope is $R = \left(\frac{1}{2}\right)^n R_0$, where R_0 is its decay rate at $t = 0$.

The counting rate after n half-lives is related to the initial counting rate:

$$R = \left(\tfrac{1}{2}\right)^n R_0$$

Divide both sides of the equation by the volume V of blood in the patient:

$$\frac{R}{V} = \left(\tfrac{1}{2}\right)^n \frac{R_0}{V}$$

We're given that $n = 2/3$, $R_0 = 600$ kBq, and, after n half-lives, the decay rate per unit volume is 60 Bq/mL:

$$60\,\text{Bq/mL} = \left(\tfrac{1}{2}\right)^{2/3} \frac{600\,\text{kBq}}{V}$$

Solving for V yields:

$$V = \left(\tfrac{1}{2}\right)^{2/3}\left(\frac{600\,\text{kBq}}{60\,\text{Bq/mL}}\right) = 6.30\times10^3\,\text{mL}$$

$$= \boxed{6.3\,\text{L}}$$

62 •• (*a*) Determine the distance of closest approach of an 8.0-MeV α particle in a head-on collision with a stationary nucleus of ^{197}Au and with a stationary nucleus of ^{10}B, neglecting the recoil of the struck nuclei. (*b*) Repeat the calculation taking into account the recoil of the struck nuclei.

Picture the Problem We can solve this problem in the center of mass reference frame for the general case of an α particle in a head-on collision with a stationary nucleus of atomic mass M u and then substitute data for a stationary nucleus of ^{197}Au and a nucleus of ^{10}B.

In the CM frame, the kinetic energy is:

$$K_{\text{CM}} = \frac{K_{\text{lab}}}{1+\dfrac{m_\alpha}{M}} = \frac{K_{\text{lab}}}{1+\dfrac{4\,\text{u}}{M}}$$

At the point of closest approach:

$$K_{\text{CM}} = \frac{kq_1q_2}{R_{\min}} = \frac{k(2e)(Ze)}{R_{\min}} = \frac{ke^2\,2Z}{R_{\min}}$$

or, because $ke^2 = 1.44$ MeV·fm,

$$K_{\text{CM}} = \frac{(1.44\,\text{MeV}\cdot\text{fm})(2Z)}{R_{\min}}$$

Solve for $R_{\min}$ to obtain:

$$R_{\min} = \frac{(1.44\,\text{MeV}\cdot\text{fm})(2Z)}{K_{\text{CM}}} \qquad (1)$$

(*a*) Neglecting the recoil of the target nucleus is equivalent to replacing K_{CM} by K_{lab}. Evaluate equation (1) for ^{197}Au:

$$R_{\min} = \frac{(1.44\,\text{MeV}\cdot\text{fm})(2\times 79)}{8.0\,\text{MeV}} = \boxed{28\,\text{fm}}$$

Evaluate equation (1) for ^{10}B:

$$R_{\min} = \frac{(1.44\,\text{MeV}\cdot\text{fm})(2\times 5)}{8.0\,\text{MeV}} = \boxed{1.8\,\text{fm}}$$

(*b*) Find K_{CM} for the ^{197}Au nucleus:

$$K_{\text{CM}} = \frac{8.0\,\text{MeV}}{1+\dfrac{4\,\text{u}}{197\,\text{u}}} = 7.841\,\text{MeV}$$

Substitute numerical values in equation (1) and evaluate R_{min}:

$$R_{\text{min}} = \frac{(1.44\,\text{MeV}\cdot\text{fm})(2\times 79)}{7.841\,\text{MeV}} = \boxed{29\,\text{fm}}$$

Note that this result is about 2% greater that R_{min} calculated ignoring recoil.

Find K_{CM} for the ^{10}B nucleus:

$$K_{\text{CM}} = \frac{8.0\,\text{MeV}}{1+\dfrac{4\,\text{u}}{10\,\text{u}}} = 5.714\,\text{MeV}$$

Substitute numerical values in equation (1) and evaluate R_{min}:

$$R_{\text{min}} = \frac{(1.44\,\text{MeV}\cdot\text{fm})(2\times 5)}{5.714\,\text{MeV}} = \boxed{2.5\,\text{fm}}$$

Note that this result is about 40% greater that R_{min} calculated ignoring recoil.

63 •• Twelve nucleons are in a one-dimensional infinite square well of length L = 3.0 fm. (*a*) Using the approximation that the mass of a nucleon is 1.0 u, find the lowest energy of a nucleon in the well. Express your answer in MeV. What is the ground-state energy of the system of 12 nucleons in the well if (*b*) all the nucleons are neutrons so that there can be no more than 2 in each spatial state and (*c*) 6 of the nucleons are neutrons and 6 are protons so that there can be as many as 4 nucleons in each spatial state? (Neglect the energy of Coulomb repulsion of the protons.)

Picture the Problem The allowed energy levels in a one-dimensional infinite square well are given by $E_n = n^2\left(\dfrac{h^2}{8mL^2}\right)$.

(*a*) The lowest energy of a nucleon of mass 1.0 u in the well corresponds to n = 1:

$$E_1 = \frac{(6.626\times 10^{-34}\ \text{J}\cdot\text{s})^2}{8(1.0\,\text{u})(1.661\times 10^{-27}\ \text{kg/u})(3.0\,\text{fm})^2} = 3.678\times 10^{-12}\ \text{J}\times\frac{1\text{eV}}{1.602\times 10^{-19}\ \text{J}} = \boxed{23\,\text{MeV}}$$

(*b*) Because neutrons are fermions, there can be no more than two per state:

$$E = 2(E_1 + E_2 + E_3 + E_4 + E_5 + E_6) = 2(E_1 + 2^2 E_1 + 3^2 E_1 + 4^2 E_1 + 5^2 E_1 + 6^2 E_1)$$
$$= 182 E_1 = 182(23\,\text{MeV}) = \boxed{4.2\,\text{GeV}}$$

(*c*) Find E for 4 protons and 4 neutrons:

$$E = 4(E_1 + E_2 + E_3) = 4(E_1 + 2^2 E_1 + 3^2 E_1)$$
$$= 56 E_1 = 56(23\,\text{MeV})$$
$$= \boxed{1.3\,\text{GeV}}$$

64 •• The helium nucleus or α particle is a very tightly bound system. Nuclei with $N = Z = 2n$, where n is an integer (for example, ^{12}C, ^{16}O, ^{20}Ne, and ^{24}Mg), can be modeled as agglomerates of α particles. (*a*) Use this model to estimate the binding energy of a pair of α particles from the atomic masses of ^{4}He and ^{16}O. Assume that the four α particles in ^{16}O form a regular tetrahedron that has one α particle at each vertex. (*b*) From the result obtained in Part (*a*) determine, on the basis of this model, the binding energy of ^{12}C and compare your result with the result obtained from the atomic mass of ^{12}C.

Picture the Problem We can apply BE = $(\Delta m)c^2$ to the model to find the binding energies and the binding energies/bond.

(*a*) Find the binding energy BE for this model:

$$\text{BE} = \left(4m_\alpha - m_{^{16}\text{O}}\right)c^2$$
$$= [4(4.002\ 603\ \text{u}) - 15.994\ 915\ \text{u}]c^2$$
$$= (0.015\ 497\ \text{u})c^2$$

Because there is a bond between adjacent α particles (4) and a bond between diagonally opposite α particles (2), there are 6 bonds for the regular tetrahedron:

$$\frac{\text{BE}}{\text{bond}} = \tfrac{1}{6}\text{BE} = \tfrac{1}{6}(0.015\ 497\,\text{u})c^2 = \tfrac{1}{6}(0.015\ 497\,\text{u})c^2\left(\frac{931.5\,\text{MeV/c}^2}{\text{u}}\right)$$
$$= \boxed{2.406\,\text{MeV}}$$

(*b*) ^{12}C has 3 pairwise α particle bonds. Find the total BE for ^{12}C with this model:

$$\text{BE}\left(^{12}\text{C}\right) = 3 \times \text{BE}\left(^{4}\text{He}\right) + 3(2.406\,\text{MeV})$$

Calculate BE(^{4}He):

$$\begin{aligned}\text{BE}\left({}^4\text{He}\right) &= \left[2\left(m_\text{p} + m_\text{n}\right) - m_{{}^4\text{He}}\right]c^2 \\ &= \left[2\left(1.007\ 825\,\text{u} + 1.008\ 665\,\text{u}\right) - 4.002\ 603\,\text{u}\right]c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right) \\ &= 28.30\,\text{MeV}\end{aligned}$$

Substitute numerical values and evaluate $\text{BE}\left({}^{12}\text{C}\right)$:

$$\text{BE}\left({}^{12}\text{C}\right) = 3\left(28.30\,\text{MeV}\right) + 3\left(2.406\,\text{MeV}\right) = \boxed{92.1\,\text{MeV}}$$

Use values in Table 40-1 to find $\text{BE}\left({}^{12}\text{C}\right)$:

$$\begin{aligned}\text{BE}\left({}^{12}\text{C}\right) &= \left[6\left(m_\text{p} + m_\text{n}\right) - m_{{}^{12}\text{C}}\right]c^2 \\ &= \left[6\left(1.007\ 825\,\text{u} + 1.008\ 665\,\text{u}\right) - 12.000\ 000\,\text{u}\right]c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right) \\ &= 92.2\,\text{MeV}\end{aligned}$$

Note that this result is in good agreement with the model.

65 •• Nuclei of a radioactive isotope that has a decay constant of λ are produced in an accelerator at a constant rate R_p. The number of radioactive nuclei N then obeys the equation $dN/dt = R_\text{p} - \lambda N$. (*a*) If N is zero at $t = 0$, sketch N versus t for this situation. (*b*) The isotope ^{62}Cu is produced at a rate of 100 per second by placing ordinary copper (^{63}Cu) in a beam of high-energy photons. The reaction is

$$\gamma + {}^{63}\text{Cu} \rightarrow {}^{62}\text{Cu} + \text{n}$$

The isotope ^{62}Cu decays by β decay and has a half-life of 10 min. After a time long enough so that $dN/dt \approx 0$, how many ^{62}Cu nuclei are there?

Picture the Problem We can separate the variables in the differential equation $dN/dt = R_\text{p} - \lambda N$ and integrate to express N as a function of t. When $dN/dt \approx 0$, $R_\text{p} - \lambda N_\infty = 0$, a condition we can use to find N_∞.

(*a*) Separate the variables in the differential equation to obtain:

$$\frac{dN}{R_\text{p} - \lambda N} = dt$$

Integrate the left side of the equation from 0 to N and the right side from 0 to t to obtain:

$$\int_0^N \frac{dN'}{R_\text{p} - \lambda N'} = \int_0^t dt'$$

Let $u = R_p - \lambda N'$. Then: $du = -\lambda dN'$

and

$$\int_0^N \frac{dN'}{R_p - \lambda N'} = -\frac{1}{\lambda}\int_{\ell_1}^{\ell_2} \frac{du}{u} = -\frac{1}{\lambda}\ln u\Big|_{\ell_1}^{\ell_2}$$

$$= -\frac{1}{\lambda}\ln(R_p - \lambda N')\Big|_0^N$$

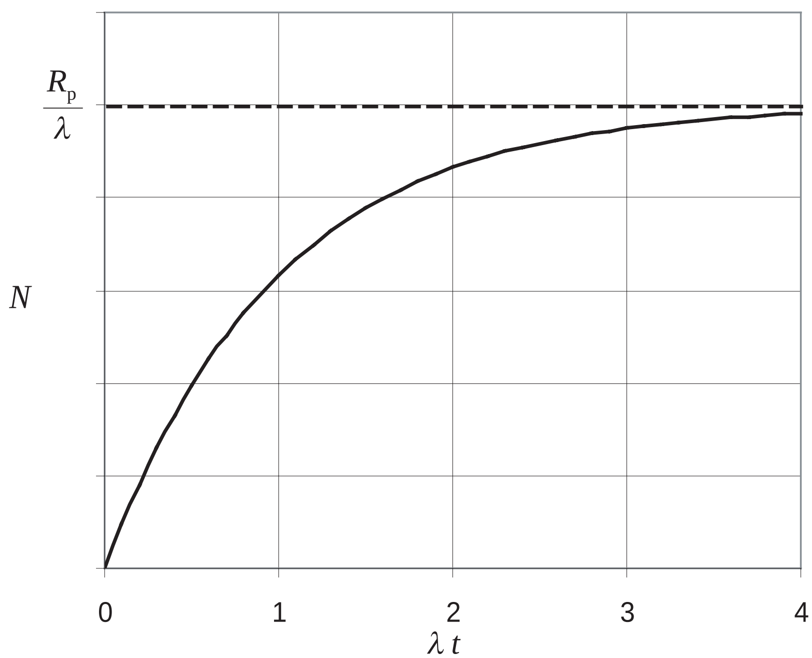
$$= -\frac{1}{\lambda}\ln(R_p - \lambda N) + \frac{1}{\lambda}\ln(R_p)$$

$$= \frac{1}{\lambda}\ln\left(\frac{R_p}{R_p - \lambda N}\right)$$

Because $\int_0^t dt' = t$:

$$\frac{1}{\lambda}\ln\left(\frac{R_p}{R_p - \lambda N}\right) = t \Rightarrow N = \frac{R_p}{\lambda}\left(1 - e^{-\lambda t}\right)$$

The following graph of $N(t) = (R_p/\lambda)(1 - e^{-\lambda t})$ was plotted using a spreadsheet program. Note that $N(t)$ approaches R_p/λ in the same manner that the charge on a capacitor approaches the value CV.



(*b*) When $dN/dt = 0$:

$$R_p - \lambda N_\infty = 0 \Rightarrow N_\infty = \frac{R_p}{\lambda}$$

The decay constant is:

$$\lambda = \frac{\ln(2)}{t_{1/2}}$$

Substitute for λ to obtain:

$$N_\infty = \frac{R_p}{\ln(2)} t_{1/2}$$

Substitute numerical values and evaluate N_∞:

$$N_\infty = \frac{100\,\text{s}^{-1}}{\ln(2)}\left(10\,\text{min} \times \frac{60\,\text{s}}{\text{min}}\right) = \boxed{8.7 \times 10^4}$$

66 •• The total energy consumed in the United States in 1 y is approximately 7.0×10^{19} J. How many kilograms of ^{235}U would be needed to provide this amount of energy if we assume that 200 MeV of energy is released by each fissioning uranium nucleus, that all of the uranium atoms undergo fission, and that all of the energy-conversion mechanisms used are 100 percent efficient?

Picture the Problem The mass of ^{235}U required is given by $m_{235} = \dfrac{N}{N_A} M_{235}$, where M_{235} is the molecular mass of ^{235}U and N is the number of fissions required to produce $7.0{\times}10^{19}$ J.

Relate the mass of ^{235}U required to the number of fissions N required:

$$m_{235} = \frac{N}{N_A} M_{235}$$

where M_{235} is the molecular mass of ^{235}U.

Because $N = \dfrac{E_{\text{annual}}}{E_{\text{per fission}}}$:

$$m_{235} = \frac{E_{\text{annual}} M_{235}}{N_A E_{\text{per fission}}}$$

Substitute numerical values in equation (1) and evaluate m_{235}:

$$m_{235} = \frac{(7.0 \times 10^{19}\,\text{J})(235\,\text{g/mol})}{\left(6.022 \times 10^{23}\,\dfrac{\text{nuclei}}{\text{mol}}\right)\left(200\,\text{MeV} \times \dfrac{1.602 \times 10^{-19}\,\text{J}}{\text{eV}}\right)} = \boxed{8.5 \times 10^5\,\text{kg}}$$

67 •• (*a*) Find the wavelength of a particle in the ground state of a one-dimensional infinite square well of length L = 2.00 fm. (*b*) Find the momentum in units of MeV/c for a particle that has this wavelength. (*c*) Show that the total energy of an electron that has this wavelength is approximately $E \approx pc$. (*d*) What is the kinetic energy of an electron in the ground state of this well? This

calculation shows that if an electron were confined in a region of space as small as a nucleus, it would have a very large kinetic energy.

Picture the Problem In the ground state of a one-dimensional infinite square well of length L the wavelength of a particle is $2L$. We can use de Broglie's equation to find p for the particle and the relationship $E^2 = E_0^2 + p^2c^2$ with $E_0 << pc$ to show that $E \approx pc$.

(a) In the ground state of a one-dimensional infinite square well of length L:

$$\lambda = 2L = 2(2.00\,\text{fm}) = \boxed{4.00\,\text{fm}}$$

(b) Use de Broglie's relation to obtain:

$$p = \frac{h}{\lambda} = \frac{hc}{\lambda c}$$

Substitute numerical values and evaluate p:

$$p = \frac{1240\,\text{eV}\cdot\text{nm}}{(4.00\,\text{fm})c} = \boxed{310\,\text{MeV}/c}$$

(c) Relate the total energy of the electron to its rest energy and momentum:

$$E^2 = E_0^2 + p^2c^2 = p^2c^2\left(1+\frac{E_0^2}{p^2c^2}\right)$$

Because $E_0 << pc$:

$$E^2 \approx p^2c^2 \Rightarrow E \approx \boxed{pc}$$

(d) The kinetic energy of an electron in the ground state of this well is given by:

$$K = E - E_0 \approx E = pc$$
$$= (310\,\text{MeV}/c)c = \boxed{310\,\text{MeV}}$$

68 •• If ^{12}C, ^{11}B, and ^{1}H have respective masses of 12.000 000 u, 11.009 306 u, and 1.007 825 u, determine the minimum energy, Q, in MeV, required to remove a proton from a ^{12}C nucleus.

Picture the Problem When a single proton is removed from a ^{12}C nucleus, a ^{11}B nucleus remains and we can use $Q = \Delta mc^2$ to determine the minimum energy required to remove a proton.

The nuclear reaction is:

$${}^{12}_{6}\text{C} + Q \rightarrow {}^{11}_{5}\text{B} + {}^{1}_{1}\text{H}$$

The minimum energy Q required is:

$$Q = \left(m_{^{11}\text{B}} + m_{^{1}\text{H}} - m_{^{12}\text{C}}\right)c^2$$

Substitute numerical values and evaluate Q:

$$Q = [(11.009\,306\,\text{u} + 1.007\,825\,\text{u}) - 12.000\,000\,\text{u}]c^2\left(\frac{931.5\,\text{MeV}/c^2}{\text{u}}\right)$$

$$= \boxed{16.0\,\text{MeV}}$$

69 ••• [SSM] Assume that a neutron decays into a proton and an electron without the emission of a neutrino. The kinetic energy shared by the proton and the electron is then 0.782 MeV. In the rest frame of the neutron, the total momentum is zero, so the momentum of the proton must be equal and opposite the momentum of the electron. This determines the ratio of the kinetic energies of the two particles, but because the electron is relativistic, the exact calculation of these relative kinetic energies is somewhat challenging. (a) Assume that the kinetic energy of the electron is 0.782 MeV and calculate the momentum p of the electron in units of MeV/c. *Hint: Use* $E^2 = p^2c^2 + (mc^2)^2$ *(Equation 39-27).* (b) Using your result from Part (a), calculate the kinetic energy $p^2/2m_p$ of the proton. (c) Because the total kinetic energy of the electron and the proton is 0.782 MeV, the calculation in Part (b) gives a correction to the assumption that the kinetic energy of the electron is 0.782 MeV. What percentage of 0.782 MeV is this correction?

Picture the Problem The momentum of the electron is related to its total energy through $E^2 = p^2c^2 + E_0^2$ and its total relativistic energy E is the sum of its kinetic and rest energies.

(a) Relate the total energy of the electron to its momentum and rest energy:

$$E^2 = p^2c^2 + E_0^2 \qquad (1)$$

The total relativistic energy E of the electron is the sum of its kinetic energy and its rest energy:

$$E = K + E_0$$

Substitute for E in equation (1) to obtain:

$$(K + E_0)^2 = p^2c^2 + E_0^2$$

Solving for p gives:

$$p = \frac{\sqrt{K(K + 2E_0)}}{c}$$

Substitute numerical values and evaluate p:

$$p=\frac{\sqrt{(0.782\,\text{MeV})(0.782\,\text{MeV}+2\times0.511\,\text{MeV})}}{c}=1.188\,\text{MeV}/c=\boxed{1.19\,\text{MeV}/c}$$

(b) Because $p_{\text{p}} = -p_{\text{e}}$:

$$K_{\text{p}}=\frac{p_{\text{p}}^2}{2m_{\text{p}}}$$

Substitute numerical values (see Table 7-1 for the rest energy of a proton) and evaluate K_{p}:

$$K_{\text{p}}=\frac{(1.188\,\text{MeV}/c)^2}{2(938.28\,\text{MeV}/c^2)}=\boxed{752\,\text{eV}}$$

(c) The percent correction is:

$$\frac{K_{\text{p}}}{K}=\frac{752\,\text{eV}}{0.782\,\text{MeV}}=\boxed{0.0962\%}$$

70 ••• In the laboratory reference frame, a neutron of mass m moving with speed v_{L} makes an elastic head-on collision with a nucleus of mass M that is at rest. (a) Show that the speed of the center of mass in the lab frame is $V = mv_{\text{L}}/(m + M)$. ($b$) What is the speed of the nucleus in the center-of-mass frame before the collision and after the collision? (c) What is the speed of the nucleus in the laboratory frame after the collision? (d) Show that the energy of the nucleus after the collision in the laboratory frame is

$$\frac{1}{2}M(2V)^2=\frac{4mM}{(m+M)^2}\left(\frac{1}{2}mv_{\text{L}}^2\right)$$

(e) Show that the fraction of the energy lost by the neutron in this elastic collision is

$$\frac{-\Delta E}{E}=\frac{4mM}{(m+M)^2}=\frac{4(m/M)}{(1+m/M)^2}$$

Picture the Problem Conservation of momentum and conservation of energy allow us to find the final speeds of the neutron and nucleus.

(a) Apply conservation of momentum to the collision to obtain:

$$(m+M)V=mv_{\text{L}}\Rightarrow V=\boxed{\left(\frac{m}{m+M}\right)v_{\text{L}}}$$

(b) In the CM frame, $V_{M\text{i}} = V$ and so:

$$V_{M\text{i}}=\boxed{V}$$

In the CM frame, $V_f = -V_i$ and so:

$$V_{Mf} = \boxed{-V}$$

(*c*) Use conservation of momentum to obtain one relation for the final velocities:

$$mv_L = mv_f + MV_{Mf} \qquad (1)$$

The equality of the initial and final kinetic energies provides a second equation relating the two final velocities. This is implemented by equating the speeds of recession and approach:

$$V_{Mf} - v_f = -(V_{Mi} - v_L) = 0 + v_L$$

and so

$$v_f = V_{Mf} - v_L$$

To eliminate v_f, substitute for mv_L in equation (1) :

$$mv_L = m(V_{Mf} - v_L) + MV_{Mf}$$

Solving for V_{Mf} yields:

$$V_{Mf} = \boxed{\left(\frac{2m}{m+M}\right)v_L}$$

(*d*) The kinetic energy of the nucleus after the collision in the laboratory frame is:

$$K_M = \tfrac{1}{2}MV_{Mf}^2$$

Substitute for V_{Mf} and simplify to obtain:

$$K_{Mf} = \tfrac{1}{2}M\left(\frac{2m}{m+M}v_L\right)^2 = \boxed{\frac{4mM}{(m+M)^2}\left(\tfrac{1}{2}mv_L^2\right)}$$

(*e*) The fraction of the energy lost by the neutron in the elastic collision is given by:

$$\frac{-\Delta E}{E} = \frac{-(K_{mf} - K_{mi})}{\frac{1}{2}mv_L^2} = \frac{-\left(\frac{1}{2}mv_f^2 - \frac{1}{2}mv_L^2\right)}{\frac{1}{2}mv_L^2} = \frac{-\frac{1}{2}m\left(v_f^2 - v_L^2\right)}{\frac{1}{2}mv_L^2}$$

Because $v_f = V_{Mf} - v_L$:

$$\frac{-\Delta E}{E} = \frac{-\frac{1}{2}m\left[(V_{Mf} - v_L)^2 - v_L^2\right]}{\frac{1}{2}mv_L^2}$$

Substituting for $V_{M\mathrm{f}}$ from Part (c) gives:

$$\frac{-\Delta E}{E}=\frac{-\frac{1}{2}m\left[\left(\left(\frac{2m}{m+M}\right)v_{\mathrm{L}}-v_{\mathrm{L}}\right)^2-v_{\mathrm{L}}^2\right]}{\frac{1}{2}mv_{\mathrm{L}}^2}=\frac{-\frac{1}{2}mv_{\mathrm{L}}^2\left[\left(\left(\frac{2m}{m+M}\right)-1\right)^2-1\right]}{\frac{1}{2}mv_{\mathrm{L}}^2}$$

$$=-\left[\left(\frac{2m}{m+M}\right)-1\right]^2-1=-\left[\left(\frac{2m}{m+M}\right)-1\right]^2-1=-\left[\frac{2m-m-M}{m+M}\right]^2-1$$

Further simplification yields:

$$\frac{-\Delta E}{E}=\frac{4mM}{(M+m)^2}=\frac{4mM}{M^2\left(1+\frac{m}{M}\right)^2}=\boxed{\frac{4m/M}{(1+m/M)^2}}$$

71 ••• (a) Use the result from Part (e) of Problem 72 to show that after N head-on collisions of a neutron with carbon nuclei at rest, the energy of the neutron is approximately $(0.714)^N E_0$, where E_0 is its original energy.
(b) How many head-on collisions are required to reduce the energy of the neutron from 2.0 MeV to 0.020 eV, assuming stationary carbon nuclei?

Picture the Problem We can use the result of Problem 70, Part (e), to find the fraction $f=E_{\mathrm{f}}/E_0$ of its initial energy lost per collision and then use this result to show that, after N collisions, $E=(0.714)^N E_0$.

(a) Determine $f=E_{\mathrm{f}}/E_0$ per collision:

$$f=\frac{E_0-\Delta E}{E_0}=1-\frac{\Delta E}{E_0}$$

From Problem 70, Part (e):

$$\frac{\Delta E}{E_0}=\frac{4m}{M\left(1+\frac{m}{M}\right)^2}$$

Substitute for $\Delta E/E_0$ in the expression for f to obtain:

$$f=1-\frac{4m}{M\left(1+\frac{m}{M}\right)^2}$$

Substitute numerical values and evaluate f:

$$f = 1 - \frac{4(1.008665\,\text{u})}{12.000000\,\text{u}\left(1 + \frac{1.008665\,\text{u}}{12.000000\,\text{u}}\right)^2} = 0.714$$

After N collisions:

$$E_{fN} = f^N E_0 = \boxed{(0.714)^N E_0} \quad (1)$$

(b) Solve equation (1) for N:

$$N = \frac{\ln\left(\frac{E_{fN}}{E_0}\right)}{\ln(0.714)}$$

Substitute numerical values and evaluate N:

$$N = \frac{\ln\left(\frac{0.020\,\text{eV}}{2.0\,\text{MeV}}\right)}{\ln(0.714)} \approx 55$$

55 head-on collisions are required to reduce the energy of the neutron from 2.0 MeV to 0.020 eV.

72 ••• On the average, a neutron loses 63 percent of its energy in a collision with a hydrogen atom and 11 percent of its energy in a collision with a carbon atom. Calculate the number of collisions needed to reduce the energy of a neutron from 2.0 MeV to 0.020 eV if the neutron collides with (a) hydrogen atoms and (b) carbon atoms.

Picture the Problem We can use the result of Problem 70, Part (e), to find the fraction $f = E_\text{f}/E_0$ of its initial energy lost per collision. Note the difference between the energy loss per collision specified here and that of the preceding problem. In the preceding problem it was assumed that all collisions are head-on collisions.

(a) Determine $f = E_\text{f}/E_0$ per collision:

$$f = \frac{E_0 - \Delta E}{E_0} = 1 - \frac{\Delta E}{E_0}$$

In a collision with a hydrogen atom:

$$\frac{\Delta E}{E_0} = 0.63 \Rightarrow f = 0.37$$

After N collisions:

$$E_{fN} = f^N E_0 = (0.37)^N E_0 \quad (1)$$

Solve equation (1) for N:

$$N = \frac{\ln\left(\frac{E_{fN}}{E_0}\right)}{\ln(0.37)} \quad (2)$$

Substitute numerical values and evaluate N:

$$N = \frac{\ln\left(\frac{0.020\,\text{eV}}{2.0\,\text{MeV}}\right)}{\ln(0.37)} \approx 19$$

19 head-on collisions with an atom of hydrogen are required to reduce the energy of the neutron from 2.0 MeV to 0.020 eV.

(*b*) In a collision with a carbon atom:

$$\frac{\Delta E}{E_0} = 0.11 \Rightarrow f = 0.89$$

Equation (2) becomes:

$$N = \frac{\ln\left(\frac{E_{fN}}{E_0}\right)}{\ln(0.89)}$$

Substitute numerical values and evaluate N:

$$N = \frac{\ln\left(\frac{0.020\,\text{eV}}{2.0\,\text{MeV}}\right)}{\ln(0.89)} \approx 160$$

160 head-on collisions with an atom of carbon are required to reduce the energy of the neutron from 2.0 MeV to 0.020 eV.

73 ••• [SSM] Frequently, the daughter nucleus of a radioactive parent nucleus is itself radioactive. Suppose the parent nucleus, designated by P, has a decay constant λ_P; while the daughter nucleus, designated by D, has a decay constant λ_D. The number of daughter nuclei N_D are then given by the solution to the differential equation

$$dN_D/dt = \lambda_P N_P - \lambda_D N_D$$

where N_P is the number of parent nuclei. (*a*) Justify this differential equation. (*b*) Show that the solution for this equation is

$$N_D(t) = \frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right)$$

where N_{P0} is the number of parent nuclei present at $t = 0$ when there are no daughter nuclei. (*c*) Show that the expression for N_D in Part (*b*) gives $N_D(t) > 0$

whether $\lambda_P > \lambda_D$ or $\lambda_D > \lambda_P$. (*d*) Make a plot of $N_P(t)$ and $N_D(t)$ as a function of time when $\tau_D = 3\tau_P$, where τ_D and τ_P are the mean lifetimes of the daughter and parent nuclei, respectively.

Picture the Problem We can differentiate $N_D(t) = \frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right)$ with respect to t to show that it is the solution to the differential equation $dN_D/dt = \lambda_P N_P - \lambda_D N_D$.

(*a*) The rate of change of N_D is the rate of generation of D nuclei minus the rate of decay of D nuclei. The generation rate is equal to the decay rate of P nuclei, which equals $\lambda_P N_P$. The decay rate of D nuclei is $\lambda_D N_D$.

(*b*) We're given that:

$$\frac{dN_D}{dt} = \lambda_P N_P - \lambda_D N_D \qquad (1)$$

$$N_D(t) = \frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right) \qquad (2)$$

$$N_P = N_{P0}e^{-\lambda_P t} \qquad (3)$$

Differentiate equation (2) with respect to t to obtain:

$$\frac{d}{dt}\left[N_D(t)\right] = \frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\frac{d}{dt}\left[\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right)\right] = \frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left[-\lambda_P e^{-\lambda_P t} + \lambda_D e^{-\lambda_D t}\right]$$

Substitute this derivative in equation (1) to obtain:

$$\frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left[-\lambda_P e^{-\lambda_P t} + \lambda_D e^{-\lambda_D t}\right] = \lambda_P N_{P0}e^{-\lambda_P t} - \lambda_D\left[\frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right)\right]$$

Multiply both sides by $\frac{\lambda_D - \lambda_P}{\lambda_D\lambda_P}$ and simplify to obtain:

$$\begin{aligned}
\frac{N_{P0}}{\lambda_D}\left[-\lambda_P e^{-\lambda_P t} + \lambda_D e^{-\lambda_D t}\right] &= \frac{\lambda_D - \lambda_P}{\lambda_D}N_{P0}e^{-\lambda_P t} - N_{P0}\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right) \\
&= N_{P0}e^{-\lambda_P t} - \frac{N_{P0}\lambda_P}{\lambda_D}e^{-\lambda_P t} - N_{P0}e^{-\lambda_P t} + N_{P0}e^{-\lambda_D t} \\
&= -\frac{N_{P0}\lambda_P}{\lambda_D}e^{-\lambda_P t} + N_{P0}e^{-\lambda_D t} \\
&= \frac{N_{P0}}{\lambda_D}\left[-\lambda_P e^{-\lambda_P t} + \lambda_D e^{-\lambda_D t}\right]
\end{aligned}$$

Because this is an identity, it confirms that equation (2) is the solution to equation (1).

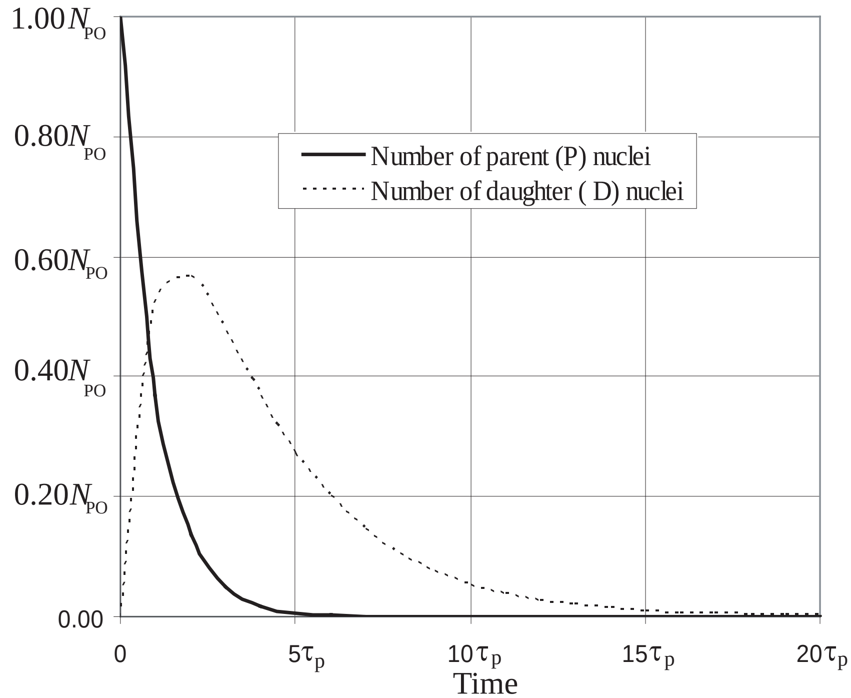
(*c*) If $\lambda_P > \lambda_D$ the denominator and expression in parentheses are both negative for $t > 0$. If $\lambda_P < \lambda_D$ the denominator and expression in parentheses are both positive for $t > 0$.

(*d*) A spreadsheet program to calculate N_P and N_D as functions of time is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
A4	0	t
A5	A4+1	$t + 1$
B4	EXP(−A4)	$N_{P0}e^{-\lambda_P t}$
C4	−1.5*(EXP(−A4) −EXP(−(1/3)*A4))	$\frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right)$

	A	B	C
1			
2			
3	*Time*	N_P	N_D
4	0	1	0
5	1	0.367879	0.522978
6	2	0.135335	0.567123
7	3	0.049787	0.477139
22	18	1.52E−08	0.003718
23	19	5.6E−09	0.002664
24	20	2.06E−09	0.001909

A graph of N_P and N_D as functions of time follows:



74 ••• Suppose isotope A decays to isotope B and has a decay constant λ_A, and isotope B in turn decays and has a decay constant λ_B. Suppose a sample contains, at $t = 0$, only isotope A nuclei. Derive an expression for the time at which the number of isotope B nuclei will be a maximum. (See Problem 75.)

Picture the Problem We can express the time at which the number of isotope B nuclei will be a maximum by setting dN_B/dt equal to zero and solving for t.

From Problem 75 we have:

$$\frac{dN_B}{dt} = \lambda_A N_A - \lambda_B N_B = 0 \text{ for extrema}$$

Replace $\lambda_A N_A$ by $\lambda_A N_{A0} e^{-\lambda_A t}$ and N_B by $\dfrac{N_{A0}\lambda_A}{\lambda_B - \lambda_A}\left(e^{-\lambda_A t} - e^{-\lambda_B t}\right)$:

$$\lambda_A N_{A0} e^{-\lambda_A t} - \lambda_B \frac{N_{A0}\lambda_A}{\lambda_B - \lambda_A}\left(e^{-\lambda_A t} - e^{-\lambda_B t}\right) = 0$$

Simplify to obtain:

$$e^{-\lambda_A t} - \frac{\lambda_B}{\lambda_B - \lambda_A}\left(e^{-\lambda_A t} - e^{-\lambda_B t}\right) = 0$$

$$(\lambda_B - \lambda_A)e^{-\lambda_A t} - \lambda_B\left(e^{-\lambda_A t} - e^{-\lambda_B t}\right) = 0$$

Remove the parentheses and combine like terms to obtain:

$$\lambda_A e^{-\lambda_A t} = \lambda_B e^{-\lambda_B t} \Rightarrow t = \boxed{\frac{\ln(\lambda_B/\lambda_A)}{\lambda_B - \lambda_A}}$$

Remarks: Note that all we've shown is that an *extreme value* exists at $t = \frac{\ln(\lambda_B/\lambda_A)}{\lambda_B - \lambda_A}$. To show that this value for *t* maximizes N_B, we need to either 1) examine the second derivative at this value for *t*, or 2) plot a graph of N_B as a function of time (see Problem 77) .

75 ••• An example of the situation discussed in Problem 75 is the radioactive isotope ^{229}Th, an α emitter that has a half-life of 7300 y. Its daughter, ^{225}Ra, is a β emitter that has a half-life of 14.8 d. In this instance, as in many instances, the half-life of the parent is much longer than the half-life of the daughter. Using the expression given in Problem 75, Part (*b*), starting with a sample of pure ^{229}Th containing N_{P0} nuclei, show that the number, N_D, of ^{225}Ra nuclei will, after several years, be given by

$$N_D = \frac{\lambda_P}{\lambda_D} N_{P0}$$

where N_P is number of ^{229}Th nuclei. The number of daughter nuclei are said to be in *secular equilibrium*.

Picture the Problem We can show that, provided $\tau_P >> \tau_D$, $e^{-\lambda_P t} - e^{-\lambda_D t} \approx 1$ and $\frac{\lambda_P}{\lambda_D - \lambda_P} \approx \frac{\lambda_P}{\lambda_D}$ and, hence, that $N_D = \frac{\lambda_P}{\lambda_D} N_{P0}$.

We have, from Problem 75 (*b*):

$$N_D(t) = \frac{N_{P0}\lambda_P}{\lambda_D - \lambda_P}\left(e^{-\lambda_P t} - e^{-\lambda_D t}\right) \quad (1)$$

Because $\tau_P >> \tau_D$:

$$\lambda_P << \lambda_D$$

When several years have passed, because $\lambda_P t << 1$:

$$e^{-\lambda_P t} - e^{-\lambda_D t} \approx 1 \quad (2)$$

Also, when $\lambda_P << \lambda_D$:

$$\frac{\lambda_P}{\lambda_D - \lambda_P} \approx \frac{\lambda_P}{\lambda_D} \quad (3)$$

Substitute (2) and (3) in (1) to obtain:

$$N_D(t) = \boxed{\frac{\lambda_P}{\lambda_D} N_{P0}}$$

Chapter 41
Elementary Particles and the Beginning of the Universe

Conceptual Problems

1 • How are baryons and mesons similar? How are they different?

Similarities	Differences
Baryons and mesons are hadrons, i.e., they participate in the strong interaction. Both are composed of quarks.	Baryons consist of three quarks and are fermions. Mesons consist of two quarks and are bosons. Baryons have baryon number +1 or −1. Mesons have baryon number 0.

2 • The muon and the pion have nearly the same masses. How do these particles differ?

Determine the Concept The muon is a lepton. It is a spin-½ particle and is a fermion. It does not participate in strong interactions. It appears to be an elementary particle like the electron. The pion is a meson. Its spin is 0 and it is a boson. It does participate in strong interactions and is composed of quarks.

3 • **[SSM]** How can you tell whether a decay proceeds by the strong interaction or the weak interaction?

Determine the Concept A decay process involving the strong interaction has a very short lifetime ($\sim 10^{-23}$ s), whereas decay processes that proceed by the weak interaction have lifetimes of order 10^{-10} s.

4 • True or false:

(*a*) All baryons are hadrons.
(*b*) All hadrons are baryons.

(*a*) True

(*b*) False. There are two kinds of hadrons-baryons, which have spin $\frac{1}{2}$ (or $\frac{3}{2}$, $\frac{5}{2}$ and so on), and mesons, which have zero or integral spin.

5 • True or false: All mesons are spin-$\frac{1}{2}$ particles.

False. Mesons have zero or integral spins.

6 • A particle made of exactly two quarks is (*a*) a meson, (*b*) a baryon, (*c*) a lepton, (*d*) either a meson or a baryon, but definitely not a lepton?

Determine the Concept A meson has 2 quarks, a baryon has 3 quarks. Hence $\boxed{(a)}$ is correct.

7 • Have any quark–antiquark combinations whose electric charge is not an integral multiplied by the fundamental charge *e* been observed?

Determine the Concept No; from Table 41-2 it is evident that any quark-antiquark combination always results in an integral or zero charge.

8 • True or false:

(*a*) A lepton is a combination of three quarks.
(*b*) The typical times for decays by the weak interaction are orders of magnitude longer than the typical times for decays by the strong interaction.
(*c*) The muon and the pion are both mesons.

(*a*) False. Leptons are not made up of quarks.

(*b*) True

(*c*) False. The muon is lepton, not a meson.

9 • True or false:

(*a*) Electrons interact with protons by the strong interaction.
(*b*) Strangeness is not conserved in reactions involving the weak interaction.
(*c*) Neutrons have zero charm.

(*a*) False. Electrons interact with protons by the electromagnetic interaction.

(*b*) True

(*c*) True

Estimation and Approximation

10 •• Grand unification theories predict that the proton has a long but finite lifetime. Current experiments based on detecting the decay of protons in water infer that this lifetime is at least 10^{32} years. Assume 10^{32} years is, in fact, the mean lifetime of the proton. Estimate the expected time between proton-decays

that occur in the water of a filled Olympic-size swimming pool. An Olympic-size swimming pool is 100 m × 25 m × 2.0 m. Give your answer in days.

Picture the Problem Assuming that the lifetime of a proton is 10^{32} y, one proton out of every 10^{32} protons should decay every year on average. Hence, we can estimate the expected time between proton-decays that occur in the water of a filled Olympic-size swimming pool by determining the number of protons N in the pool and dividing 10^{32} y by this number.

The mean time between disintegrations is the ratio of the lifetime of the protons to the number of protons N in the pool:

$$\Delta t_{\text{mean}} = \frac{10^{32}\ \text{y}}{N} \qquad (1)$$

The number of protons N in the pool is related to the mass of water in the pool M_{water}, the molar mass of water $m_{\text{molar, water}}$, and the number of protons per molecule n:

$$\frac{N}{M_{\text{water}}} = \frac{nN_{\text{A}}}{m_{\text{molar, water}}}$$

Solve for N to obtain:

$$N = \frac{nN_{\text{A}}M_{\text{water}}}{m_{\text{molar, water}}}$$

Because the mass of the water is the product of its density and the volume of the pool:

$$N = \frac{nN_{\text{A}}\rho_{\text{water}}V_{\text{pool}}}{m_{\text{molar, water}}}$$

Substituting for N in equation (1) yields:

$$\Delta t_{\text{mean}} = \frac{10^{32}\ \text{y}}{\dfrac{nN_{\text{A}}\rho_{\text{water}}V_{\text{pool}}}{m_{\text{molar, water}}}} = \frac{\left(10^{32}\ \text{y}\right)m_{\text{molar, water}}}{nN_{\text{A}}\rho_{\text{water}}V_{\text{pool}}}$$

Because each molecule of water has 10 protons:

$$n = 10\,\frac{\text{protons}}{\text{molecule}}$$

Substitute numerical values and evaluate Δt_{mean}:

$$\Delta t_{\text{mean}} = \frac{\left(10^{32}\ \text{y}\right)\left(18\,\frac{\text{g}}{\text{mol}}\times\frac{1\,\text{kg}}{10^{3}\ \text{g}}\right)}{\left(10\,\frac{\text{protons}}{\text{molecule}}\right)\left(6.02\times10^{23}\,\frac{\text{molecules}}{\text{mol}}\right)\left(10^{3}\,\frac{\text{kg}}{\text{m}^{3}}\right)\left(100\,\text{m}\right)\left(25\,\text{m}\right)\left(2.0\,\text{m}\right)}$$

$$= 0.0598\,\text{y} = 0.0598\,\text{y}\times\frac{365.24\,\text{d}}{\text{y}} \approx \boxed{22\,\text{d}}$$

11 •• Table 41-6 lists some properties of the four fundamental interactions. To better understand the significance of this table, confirm the ratio of the numerical entries in the second and fourth column of the last row of the table by estimating the ratio of the electromagnetic force to the gravitational force between two protons of a nucleus.

Picture the Problem We can use $F_{\text{em}} = kq_{\text{proton}}^2 / r_{\text{nucleus}}^2$ and $F_{\text{grav}} = Gm_{\text{proton}}^2 / r_{\text{nucleus}}^2$ to estimate the ratio of the electromagnetic and gravitational forces between two protons located in a nucleus.

The electromagnetic force between two protons located in a nucleus is given by:

$$F_{\text{em}} = \frac{kq_{\text{proton}}^2}{r_{\text{nucleus}}^2}$$

The gravitational force between these same protons is given by:

$$F_{\text{grav}} = \frac{Gm_{\text{proton}}^2}{r_{\text{nucleus}}^2}$$

Divide F_{em} by F_{grav} to obtain:

$$\frac{F_{\text{em}}}{F_{\text{grav}}} = \frac{\dfrac{kq_{\text{proton}}^2}{r_{\text{nucleus}}^2}}{\dfrac{Gm_{\text{proton}}^2}{r_{\text{nucleus}}^2}} = \frac{kq_{\text{proton}}^2}{Gm_{\text{proton}}^2}$$

Substitute numerical values and evaluate $F_{\text{em}}/F_{\text{grav}}$:

$$\frac{F_{\text{em}}}{F_{\text{grav}}} = \frac{\left(8.99\times10^{9}\,\frac{\text{N}\cdot\text{m}^2}{\text{C}^2}\right)\left(1.60\times10^{-19}\ \text{C}\right)^2}{\left(6.67\times10^{-11}\,\frac{\text{N}\cdot\text{m}^2}{\text{kg}^2}\right)\left(1.67\times10^{-27}\ \text{kg}\right)^2} = \boxed{1.24\times10^{36}}$$

Spin and Antiparticles

12 • Two pions at rest annihilate according to the reaction $\pi^+ + \pi^- \to \gamma + \gamma$. (*a*) Why must the energies of the two γ-rays be equal? (*b*) Find the energy of each γ-ray. (*c*) Find the wavelength of each γ-ray.

Picture the Problem We can use both conservation of energy and momentum to explain why the energies of the two γ-rays must be equal. We can find the energy of each γ-ray in Table 41-1 and find their wavelengths using $\lambda = hc/E$.

(*a*) The initial momentum is zero; therefore, the final momentum must be zero. The momentum of the photon is E/c. To conserve both momentum and energy the two photons must have the same momentum magnitude. Hence they must have the same energy.

(*b*) From Table 41-1:

$$E_\gamma = \boxed{139.6\,\text{MeV}}$$

(*c*) The wavelength of each γ ray is given by:

$$\lambda = \frac{hc}{E} = \frac{1240\,\text{MeV}\cdot\text{fm}}{E}$$

Substitute numerical values and evaluate λ:

$$\lambda = \frac{1240\,\text{MeV}\cdot\text{fm}}{139.6\,\text{MeV}} = \boxed{8.88\,\text{fm}}$$

13 • Find the minimum energy of the photon needed for the following pair-production reactions: (*a*) $\gamma \to \pi^+ + \pi^-$, (*b*) $\gamma \to \text{p} + \text{p}^-$, and (*c*) $\gamma \to \mu^- + \mu^+$.

Picture the Problem In each case, the required energy is given by $E = 2mc^2$ where m is mass of each particle produced in the pair-production reaction. These masses can be found in Tables 41-1 and 41-3.

(*a*) For $\gamma \to \pi^+ + \pi^-$:

$$E = 2m_\pi c^2 = 2\left(139.6\,\text{MeV}/c^2\right)c^2 = \boxed{279.2\,\text{MeV}}$$

(*b*) For $\gamma \to \text{p} + \text{p}^-$:

$$E = 2m_\text{p} c^2 = 2\left(938.3\,\text{MeV}/c^2\right)c^2 = \boxed{1877\,\text{MeV}}$$

(*c*) For $\gamma \to \mu^- + \mu^+$:

$$E = 2m_\mu c^2 = 2\left(105.659\,\text{MeV}/c^2\right)c^2 = \boxed{211.3\,\text{MeV}}$$

The Conservation Laws

14 • State which of the following decays or reactions violate one or more of the conservation laws, and give the law or laws violated in each case:
a) $p^+ \to n + e^+ + \overline{\nu}_e$, (*b*) $n \to p^+ + \pi^-$, (*c*) $e^+ + e^- \to \gamma$, (*d*) $p + p^- \to \gamma + \gamma$, and (*e*) $\overline{\nu}_e + p \to n + e^+$.

Picture the Problem We need to check for conservation of energy, charge, baryon number, and lepton number.

(*a*) Energy conservation:

Because $m_p < m_n$, energy conservation is violated.

Charge conservation:
$+e \to 0 + e + 0 = +e$

Because the net charge is $+e$ before and after the decay, charge is conserved.

Baryon number:
$+1 \to +1 + 0 + 0 = +1$

Because B is +1 before and after the decay, baryon number is conserved.

Lepton number; electrons:
$0 \to 0 + 0 + 0 = 0$

Because $L_e = 0$ before and after the decay, the lepton number for electrons is conserved.

This process is not allowed because it violates conservation of energy.

(*b*) Energy conservation:

Because $m_n < m_p + m_{\pi^-}$, energy conservation is violated.

Charge conservation:
$0 \to +e + (-e) = 0$

Because the net charge is 0 before and after the decay, charge is conserved.

Baryon number:
$+1 \to +1 + 0 = +1$

Because $B = +1$ before and after the decay, baryon number is conserved.

Lepton number; electrons:
$0 \to 0 + 0 = 0$

Because $L = 0$ before and after the decay, lepton number is conserved.

Because energy is not conserved, this decay is not allowed.

(*c*) Momentum conservation is violated. Two (or more) γ rays must be emitted to conserve momentum.

(*d*) Energy conservation:	Energy is conserved.
Charge conservation: $+1 + (-1) \to 0 + 0 \ = 0$	Because the net charge is zero before and after the decay, charge is conserved.
Baryon number: $+1 + (-1) \to 0 + 0 \ = 0$	Because $B = 0$ before and after the decay, baryon number is conserved.
Lepton number; electrons: $0 \to 0 + 0 + 0 = 0$	Because $L_e = 0$ before and after the decay, the lepton number for electrons is conserved.

Because none of the conservation laws are violated, this is an allowed process.

(*e*) Energy conservation:	Because $m_p < m_n + m_{e^+}$, energy is conserved.
Charge conservation: $0 + 1 \to 0 + 1 \ = 1$	Because the net charge is one before and after the decay, charge is conserved.
Baryon number: $0 + 1 \to +1 + 0 \ = +1$	Because $B = +1$ before and after the decay, baryon number is conserved.
Lepton number; electrons: $-1 + 0 \to 0 + (-1) = -1$	Because $L_e = -1$ before and after the decay, the lepton number for electrons is conserved.

Because none of the conservation laws are violated, this is an allowed process.

15 • Determine the change in strangeness in each reaction that follows, and state whether the each decay can proceed by the strong interaction, by the weak interaction, or not at all: (*a*) $\Omega^- \to \Xi^0 + \pi^-$, (*b*) $\Xi^0 \to p + \pi^- + \pi^0$, and (*c*) $\Lambda^0 \to p + \pi^-$.

Picture the Problem The decay will occur via the strong interaction if strangeness is conserved. If $\Delta S = \pm 1$, it will occur via the weak interaction. If S changes by more than 1, the decay will not occur.

(*a*) List the strangeness of Ω^-, Ξ^0, and π^-:

Ω^-: $S = -3$
Ξ^0: $S = -2$
π^-: $S = 0$

Determine ΔS:

$$\Delta S = -2 - (-3) = \boxed{+1}$$

Because $\Delta S = +1$, the reaction can proceed via the weak interaction.

(*b*) List the strangeness of Ξ^0, p, π^-, and π^0:

Ξ^0: $S = -2$
p: $S = 0$
π^-: $S = 0$
π^0: $S = 0$

Determine ΔS:

$$\Delta S = 0 - (-2) = \boxed{+2}$$

Because $\Delta S = +2$, the reaction is not allowed.

(*c*) List the strangeness of Λ^0, p^+, and π^-:

Λ^0: $S = -1$
p^+: $S = 0$
π^-: $S = 0$

Determine ΔS:

$$\Delta S = 0 - (-1) = \boxed{+1}$$

Because $\Delta S = +1$, the reaction can proceed via the weak interaction.

16 • Determine the change in strangeness for each decay, and state whether each decay can proceed by the strong interaction, by the weak interaction, or not at all: (*a*) $\Omega^- \to \Lambda^0 + K^-$ and (*b*) $\Xi^0 \to p + \pi^-$.

Picture the Problem The decay will occur via the strong interaction if strangeness is conserved. If $\Delta S = \pm 1$, it will occur via the weak interaction. If S changes by more than 1, the decay will not occur.

(*a*) List the strangeness of Ω^-, Λ^0, and K^-:

Ω^-: $S = -3$
Λ^0: $S = -1$
K^-: $S = -1$

Determine ΔS:

$$\Delta S = -1 - 1 - (-3) = \boxed{+1}$$

Because $\Delta S = +1$, the reaction can proceed via the weak interaction.

(*b*) List the strangeness of Ξ^0, p, and π^-:

Ξ^0: $S = -2$
p: $S = 0$
π^-: $S = 0$

Determine ΔS:

$$\Delta S = 0-(-2)=\boxed{+2}$$

Because $\Delta S = +2$, the reaction is not allowed.

17 • Determine the change in strangeness for each decay, and state whether each decay can proceed by the strong interaction, by the weak interaction, or not at all: (*a*) $\Omega^- \to \Lambda^0 + \overline{\nu}_e + e^-$ and (*b*) $\Sigma^+ \to p + \pi^0$.

Picture the Problem The decay will occur via the strong interaction if strangeness is conserved. If $\Delta S = \pm 1$, it will occur via the weak interaction. If *S* changes by more than 1, the decay will not occur.

(*a*) List the strangeness of Ω^-, Λ^0, $\overline{\nu}_e$, and e^-:

Ω^-: $S = -3$
Λ^0: $S = -1$
$\overline{\nu}_e$: $S = 0$
e^-: $S = 0$

Determine ΔS:

$$\Delta S = -1-(-3)=\boxed{+2}$$

Because $\Delta S = +2$, the reaction is not allowed.

(*b*) List the strangeness of Σ^+, p, and π^0:

Σ^+: $S = -1$
p: $S = 0$
π^0: $S = 0$

Determine ΔS:

$$\Delta S = 0-(-1)=\boxed{+1}$$

Because $\Delta S = +1$, the reaction can proceed via the weak interaction.

18 • (*a*) Which of the following decays of the τ particle is possible?

$$\tau \to \mu^- + \overline{\nu}_\mu + \nu_\tau$$
$$\tau \to \mu^- + \nu_\mu + \overline{\nu}_\tau$$

(*b*) Explain why the other decay is not possible. (*c*) Calculate the kinetic energy of the decay products for the decay that is possible.

Picture the Problem We can decide whether the given decays of the τ particle are possible by determining whether energy conservation is satisfied and whether conservation of both the τ and μ lepton numbers is satisfied.

(a) The decay $\tau \to \mu^- + \overline{\nu}_\mu + \nu_\tau$ is allowed. The decay satisfies energy conservation and conservation of both the τ and μ lepton numbers.

(b) The decay $\tau \to \mu^- + \nu_\mu + \overline{\nu}_\tau$ is not allowed. The decay scheme does not conserve τ and μ lepton numbers.

(c) The total kinetic for the decay $\tau \to \mu^- + \overline{\nu}_\mu + \nu_\tau$ is:

$$K_{\text{tot}} = m_\tau c^2 - m_\mu c^2$$

From Table 41-3 we have:

$$m_\tau = 1784\,\text{MeV}/c^2$$

and

$$m_\mu = 105.659\,\text{MeV}/c^2$$

Substitute numerical values and evaluate K_{tot}:

$$K_{\text{tot}} = \left(1784\,\text{MeV}/c^2\right)c^2 - \left(106\,\text{MeV}/c^2\right)c^2$$
$$= \boxed{1678\,\text{MeV}}$$

Remarks: Note that the kinetic energy of the individual decay products cannot be determined from the decay scheme alone.

19 •• **[SSM]** Using **Error! Reference source not found.** and the laws of conservation of charge number, baryon number, strangeness, and spin, identify the unknown particle, symbolized by (?), in each of the following reactions: (a) p + π^- $\to$ Σ^0 + (?),
(b) p + p $\to$ π^+ + n + K^+ + (?), and (c) p + K^- $\to$ Ξ^- +(?)

Picture the Problem We can systematically determine Q, B, S, and s for each reaction and then use these values to identify the unknown particles.

(a) For the strong reaction:

$$\text{p} + \pi^- \to \Sigma^0 + (?)$$

Charge number:

$$+1 - 1 = 0 + Q \Rightarrow Q = 0$$

Baryon number:

$$+1 + 0 = +1 + B \Rightarrow B = 0$$

Strangeness:

$$0 + 0 = -1 + S \Rightarrow S = +1$$

Spin:

$$+\tfrac{1}{2} + 0 = +\tfrac{1}{2} + s \Rightarrow s = 0$$

These properties indicate that the particle is the kaon $\boxed{K^0}$.

(*b*) For the strong reaction: $p + p \rightarrow \pi^+ + n + K^+ + (?)$

Charge number: $+1 + 1 = +1 + 0 + 1 + Q \Rightarrow Q = 0$

Baryon number: $+1 + 1 = 0 + 1 + 0 + B \Rightarrow B = +1$

Strangeness: $0 + 0 = 0 + 0 + 1 + S \Rightarrow S = -1$

Spin: $+\frac{1}{2} + \frac{1}{2} = 0 + \frac{1}{2} + 0 + s \Rightarrow s = +\frac{1}{2}$

These properties indicate that the particle is either the $\boxed{\Sigma^0}$ or the $\boxed{\Lambda^0}$ baryon.

(*c*) For the strong reaction: $p + \overline{K}^- \rightarrow \Xi^- + (?)$

Charge number: $+1 - 1 = -1 + Q \Rightarrow Q = +1$

Baryon number: $+1 + 0 = +1 + B \Rightarrow B = 0$

Strangeness: $0 - 1 = -2 + S \Rightarrow S = +1$

Spin: $+\frac{1}{2} + 0 = +\frac{1}{2} + s \Rightarrow s = 0$

These properties indicate that the particle is the kaon $\boxed{K^+}$.

20 •• Test the following decays for violation of the conservation of energy, electric charge, baryon number, and lepton number: (*a*) $n \rightarrow \pi^+ + \pi^- + \mu^+ + \mu^-$ and (*b*) $\pi^0 \rightarrow e^+ + e^- + \gamma$. Assume that linear momentum and angular momentum are conserved. State which conservation laws (if any) are violated in each decay.

Picture the Problem A decay process is allowed if energy, charge, baryon number, and lepton number are conserved.

(*a*) Energy conservation: Because $m_n > 2m_\pi + 2m_\mu$, energy conservation is not violated.

Charge conservation:
$0 \rightarrow +1 + (-1) + 1 + (-1) = 0$

Because the total charge is 0 before and after the decay, charge is conserved.

Baryon number:
$1 \rightarrow 0 + 0 + 0 + 0 = 0$

Because baryon number changes from +1 to 0, conservation of baryon number is violated.

Lepton number:
$0 \to 0 + 0 + 1 + (-1) = 0$

Because $L_{\mu} = 0$ before and after the decay, the lepton number for muons is conserved.

Not allowed. The decay violates conservation of baryon number.

(*b*) Energy conservation:

Because $m_{\pi} > 2m_{\mathrm{e}}$, energy conservation is not violated.

Charge conservation:
$0 \to +1 + (-1) + 0 = 0$

Because the total charge is 0 before and after the decay, charge is conserved.

Baryon number:
$0 \to 0 + 0 + 0 + 0 = 0$

Because $B = 0$ before and after the decay, the baryon number is conserved.

Lepton number:
$0 \to +1 + (-1) + 0 = 0$

Because $L_{\mathrm{e}} = 0$ before and after the decay, the lepton number for electrons is conserved.

Allowed. The decay satisfies all the conservation laws.

Quarks

21 • Find the baryon number, charge, and strangeness for the following quark combinations and identify the hadron: (*a*) *uud*, (*b*) *udd*, (*c*) *uus*, (*d*) *dds*, (*e*) *uss*, and (*f*) *dss*.

Picture the Problem For each quark combination we can determine the baryon number *B*, the charge *Q*, and the strangeness *S* (from Table 41-2) and then use Table 41-1 to find a match and complete the following table.

	Combination	*B*	*Q*	*S*	hadron
(*a*)	*uud*	1	+1	0	p^+
(*b*)	*udd*	1	0	0	n
(*c*)	*uus*	1	+1	−1	Σ^+
(*d*)	*dds*	1	−1	−1	Σ^-
(*e*)	*uss*	1	0	−2	Ξ^0
(*f*)	*dss*	1	−1	−2	Ξ^-

22 • Find the baryon number, charge, and strangeness for the following quark combinations: (*a*) $u\overline{d}$, (*b*) $\overline{u}d$, (*c*) $u\overline{s}$, and (*d*) $\overline{u}s$.

Picture the Problem For each quark combination we can determine the baryon number *B*, the charge *Q*, and the strangeness *S* (from Table 41-2) and then use Table 41-1 to find a match and complete the following table.

	Combination	B	Q	S	hadron
(*a*)	$u\overline{d}$	0	+1	0	π^+
(*b*)	$\overline{u}d$	0	−1	0	π^-
(*c*)	$u\overline{s}$	0	+1	+1	K^+
(*d*)	$\overline{u}s$	0	−1	−1	K^-

23 • The Δ^{++} particle is a baryon that decays by the strong interaction. Its strangeness, charm, topness, and bottomness are all zero. What combination of quarks gives a particle that has these properties?

Determine the Concept From Table 41-2 we see that to satisfy the conditions of charge = +2 and zero strangeness, charm, topness, and bottomness, the quark combination must be *uuu*.

24 • Find a possible combination of quarks that gives the correct values for electric charge, baryon number, and strangeness for (*a*) K^+ and (*b*) K^0.

Picture the Problem Because K^+ and K^0 are mesons, they consist of a quark and an antiquark. We can use Tables 41-1 and 41-2 to find combinations of quarks with the correct values for electric charge, baryon number, and strangeness for these particles.

(*a*) For K^+ we need:

$$Q = +1$$
$$B = 0$$
$$S = +1$$

A combination of quarks with these properties is $\boxed{u\overline{s}.}$

(*b*) For K^0 we need:

$$Q = 0$$
$$B = 0$$
$$S = +1$$

A combination of quarks with these properties is $\boxed{d\overline{s}.}$

25 • The D^+ meson has zero strangeness, but it has charm of +1. (*a*) What is a possible quark combination that will give the correct properties for this particle? (*b*) Repeat Part (*a*) for the D^- meson, which is the antiparticle of the D^+ meson.

Determine the Concept Because D^+ and D^- are mesons, they consist of a quark and an antiquark.

(*a*) $B = 0$, so we must look for a combination of quark and antiquark. Because it has charm of +1, one of the quarks must be *c*. Because the charge is +*e*, the antiquark must be $\overline{d}$. The possible combination for D^+ is $\boxed{c\overline{d}.}$.

(*b*) Because D^- is the antiparticle of D^+, the quark combination is $\boxed{\overline{c}d.}$

26 • Find a possible combination of quarks that gives the correct values for electric charge, baryon number, and strangeness for (*a*) K^- (the K^- is the antiparticle of the K^+) and (*b*) $\overline{K}^0$.

Picture the Problem We can use Tables 41-1 and 41-2 to find combinations of quarks with the correct values for electric charge, baryon number, and strangeness for these particles. Because K^- and $\overline{K}^0$ are mesons, they consist of a quark and an antiquark.

(*a*) For K^- we need:

$$Q = -1$$
$$B = 0$$
$$S = -1$$

A combination of quarks with these properties is $\boxed{\overline{u}s.}$

(*b*) For $\overline{K}^0$ we need:

$$Q = 0$$
$$B = 0$$
$$S = -1$$

A combination of quarks with these properties is $\boxed{\overline{d}s.}$

Remarks: An alternative solution could take advantage of our results in Problem 24 for the antiparticles K^+ and K^0.

27 •• **[SSM]** Find a possible quark combination for the following particles: (*a*) Λ^0, (*b*) p^-, and (*c*) Σ^-.

Picture the Problem Because Λ^0, p^-, and Σ^- are baryons, they are made up of three quarks. We can use Tables 41-1 and 41-2 to find combinations of quarks with the correct values for electric charge, baryon number, and strangeness for these particles.

(*a*) For Λ^0 we need:

$$Q = 0$$
$$B = +1$$
$$S = -1$$

The quark combination that satisfies these conditions is $\boxed{uds.}$

(*b*) For p^- we need:

$$Q = -1$$
$$B = -1$$
$$S = +1$$

The quark combination that satisfies these conditions is $\boxed{\bar{u}\bar{u}\bar{d}.}$

(*c*) For Σ^- we need:

$$Q = -1$$
$$B = +1$$
$$S = -1$$

The quark combination that satisfies these conditions is $\boxed{dds.}$

28 •• Find a possible quark combination for the following particles: (*a*) $\bar{n}$, (*b*) Ξ^0, and (*c*) Σ^+.

Picture the Problem Because $\bar{n}$, Ξ^0, and Σ^+ are baryons, they are made up of three quarks. We can use Tables 41-1 and 41-2 to find combinations of quarks with the correct values for electric charge, baryon number, and strangeness for these particles.

(*a*) For $\bar{n}$ we need:

$$Q = 0$$
$$B = -1$$
$$S = 0$$

The quark combination that satisfies these conditions is $\boxed{\bar{u}\bar{d}\bar{d}.}$

(*b*) For Ξ^0 we need:

$$Q = 0$$
$$B = +1$$
$$S = -2$$

The quark combination that satisfies these conditions is $\boxed{uss.}$

(*c*) For Σ^+ we need:

$$Q = +1$$
$$B = +1$$
$$S = -1$$

The quark combination that satisfies these conditions is $\boxed{uus.}$

29 •• Find a possible quark combination for the following particles: (*a*) Ω^- and (*b*) Ξ^-.

Picture the Problem Because Ω^- and Ξ^- are baryons, they are made up of three quarks. We can use Tables 41-1 and 41-2 to find combinations of quarks with the correct values for electric charge, baryon number, and strangeness for these particles.

(*a*) For Ω^- we need:

$$Q = -1$$
$$B = +1$$
$$S = -3$$

The quark combination that satisfies these conditions is $\boxed{sss.}$

(*b*) For Ξ^- we need:

$$Q = -1$$
$$B = +1$$
$$S = -2$$

The quark combination that satisfies these conditions is $\boxed{ssd.}$

30 •• State the properties of the particles made up of the following quarks: (*a*) *ddd*, (*b*) $u\bar{c}$, (*c*) $u\bar{b}$, and (*d*) $\bar{s}\bar{s}\bar{s}$.

Picture the Problem We can use Table 41-2 to identify the properties of the particles made up of the given quarks.

	Particle	Q	B	S	Charm	Topness	Bottomness
(*a*)	*ddd*	−1	+1	0	0	0	0
(*b*)	$u\bar{c}$	0	0	0	−1	0	0
(*c*)	$u\bar{b}$	+1	0	0	0	0	−1
(*d*)	$\bar{s}\bar{s}\bar{s}$	+1	−1	+3	0	0	0

The Evolution of the Universe

31 • [SSM] A galaxy is receding from Earth at 2.5 percent the speed of light. Estimate the distance from Earth to this galaxy.

Picture the Problem We can use Hubble's law to find the distance from Earth to this galaxy.

The recessional velocity of galaxy is related to its distance by Hubble's law:

$$v = Hr \Rightarrow r = \frac{v}{H}$$

Substitute numerical values and evaluate *r*:

$$r = \frac{(0.025)c}{\dfrac{23\text{ km/s}}{10^6\, c\cdot\text{y}}} = \frac{(0.025)(2.998\times10^5\text{ km/s})}{\dfrac{23\text{ km/s}}{10^6\, c\cdot\text{y}}} = \boxed{3.3\times10^8\, c\cdot\text{y}}$$

32 • Estimate the speed of a galaxy that is 12×10^9 c·y away from us.

Picture the Problem We can use Hubble's law to find the speed of the galaxy.

The recessional velocity of the galaxy is related to its distance by Hubble's law:

$$v = Hr$$

Substitute numerical values and evaluate *v*:

$$v = \left(\frac{23\text{ km/s}}{10^6\, c\cdot\text{y}}\right)(12\times10^9\, c\cdot\text{y})\left(\frac{c}{2.998\times10^5\text{ km/s}}\right) = \boxed{0.92c}$$

33 •• The Doppler frequency shift for a light from a source that is receding from a stationary receiver is given by $f' = f_0\sqrt{(1-\beta)/(1+\beta)}$, where $\beta = v/c$ (Equation 39-16*b*). Show that the Doppler wavelength shift for light is $\lambda' = \lambda_0\sqrt{(1+\beta)/(1-\beta)}$.

Picture the Problem We can substitute for f' and f_0, using $v = f\lambda$, in Equation 39-16*b* to show that the relativistic wavelength shift is $\lambda' = \lambda_0\sqrt{\dfrac{1+\beta}{1-\beta}}$.

From Equation 39-16*b*:

$$f' = f_0\sqrt{\frac{1-\beta}{1+\beta}}$$

Express f' and f_0 in terms of λ' and λ_0:

$$f' = \frac{c}{\lambda'} \text{ and } f_0 = \frac{c}{\lambda_0}$$

Substitute for f' and f_0 to obtain:

$$\frac{c}{\lambda'} = \frac{c}{\lambda_0}\sqrt{\frac{1-\beta}{1+\beta}} \Rightarrow \lambda' = \boxed{\lambda_0\sqrt{\frac{1+\beta}{1-\beta}}}$$

34 •• The red line in the spectrum of atomic hydrogen is frequently referred to as the Hα line, and it has a wavelength of 656.3 nm. Using Hubble's law and the Doppler equation for light from Problem 33, determine the wavelength of the Hα line in the spectrum emitted from galaxies at distances of (*a*) 5.00×10^6 *c*·y, (*b*) 500×10^6 *c*·y, and (*c*) 5.00×10^9 *c*·y from Earth.

Picture the Problem Using Hubble's law, we can rewrite the equation from Problem 33 as $\lambda' = \lambda_0\sqrt{\frac{c+Hr}{c-Hr}}$.

From Problem 33 we have:

$$\lambda' = \lambda_0\sqrt{\frac{1+\beta}{1-\beta}} = \lambda_0\sqrt{\frac{1+v/c}{1-v/c}}$$

Use Hubble's law to relate v to r:

$$v = Hr$$

Substitute for v and simplify to obtain:

$$\lambda' = \lambda_0\sqrt{\frac{1+Hr/c}{1-Hr/c}} = \lambda_0\sqrt{\frac{c+Hr}{c-Hr}}$$

(*a*) For $r = 5.00 \times 10^6$ *c*·y:

$$\lambda' = 656.3\,\text{nm}\sqrt{\frac{2.998\times10^5\text{ km/s}+\left(\frac{23\text{ km/s}}{10^6 c\cdot\text{y}}\right)\left(5.00\times10^6 c\cdot\text{y}\right)}{2.998\times10^5\text{ km/s}-\left(\frac{23\text{ km/s}}{10^6 c\cdot\text{y}}\right)\left(5.00\times10^6 c\cdot\text{y}\right)}} = \boxed{6.6\times10^{-7}\text{ m}}$$

(*b*) For $r = 500 \times 10^6\ c{\cdot}\text{y}$:

$$\lambda' = 656.3\,\text{nm}\sqrt{\frac{2.998\times10^5\ \text{km/s} + \left(\dfrac{23\ \text{km/s}}{10^6\,c\cdot\text{y}}\right)\left(500\times10^6\,c\cdot\text{y}\right)}{2.998\times10^5\ \text{km/s} - \left(\dfrac{23\ \text{km/s}}{10^6\,c\cdot\text{y}}\right)\left(500\times10^6\,c\cdot\text{y}\right)}} = \boxed{6.8\times10^{-7}\ \text{m}}$$

(*c*) For $r = 5.00 \times 10^9\ c{\cdot}\text{y}$:

$$\lambda' = 656.3\,\text{nm}\sqrt{\frac{2.998\times10^5\ \text{km/s} + \left(\dfrac{23\ \text{km/s}}{10^6\,c\cdot\text{y}}\right)\left(5.00\times10^9\,c\cdot\text{y}\right)}{2.998\times10^5\ \text{km/s} - \left(\dfrac{23\ \text{km/s}}{10^6\,c\cdot\text{y}}\right)\left(5.00\times10^9\,c\cdot\text{y}\right)}} = \boxed{9.8\times10^{-7}\ \text{m}}$$

General Problems

35 • (*a*) What conditions are necessary for a hadron and its antiparticle to be identical? (*b*) Find the quark combination of both the hadron and its antiparticle for both the π^0 and the Ξ^0 particles. (*c*) Of the π^0 and the Ξ^0 particles, which, if any, is its own antiparticle?

Determine the Concept

(*a*) Baryon number and lepton numbers are conserved quantities. A particle and its antiparticle must have baryon numbers that add to zero and lepton numbers that add to zero. Thus, for a particle and its antiparticle to be identical, its baryon number and all three of its lepton numbers must equal zero. This means it cannot be a lepton or a baryon, so it must be a meson. A particle and its antiparticle have the complementary quark content. That is, if each quark in a particle is replaced by its antiquark, then the resulting entity is the antiparticle of the particle.

(*b*) The quark combination for the π^0 is a linear combination of $u\overline{u}$ and $d\overline{d}$ and the quark combination for the $\overline{\pi}^0$ is a linear combination of $\overline{u}u$ and $\overline{d}d$. The quark combination for the Ξ^0 is uss and that of the $\overline{\Xi}^0$ is $\overline{u}\overline{s}\overline{s}$.

(*c*) The π^0 is a meson with quark content of a linear combination of $u\overline{u}$ and $d\overline{d}$, so the π^0 is its own antiparticle. The Ξ^0 is a baryon. As is explained in the answer to Part (*a*), a baryon cannot be its own antiparticle.

36 •• The red line in the spectrum of atomic hydrogen is frequently referred to as the Hα line, and it has a wavelength of 656.3 nm. Light from a distant galaxy shows a redshift of the Hα line of hydrogen to a wavelength of 1458 nm.

(*a*) What is the recessional velocity of the galaxy? (*b*) Estimate the distance to this galaxy.

Picture the Problem We can solve the equation derived in Problem 33 for the recessional velocity of the galaxy and then use Hubble's equation to estimate the distance to the galaxy.

(*a*) From Problem 33 we have:

$$\lambda' = \lambda_0\sqrt{\frac{1+v/c}{1-v/c}} \Rightarrow \frac{1+v/c}{1-v/c} = \left(\frac{\lambda'}{\lambda_0}\right)^2$$

Substitute numerical values for λ' and λ_0:

$$\frac{1+v/c}{1-v/c} = \left(\frac{1458\text{ nm}}{656.3\text{ nm}}\right)^2 = 4.935$$

Simplify to obtain:

$$4.953\left(1-\frac{v}{c}\right) = 1+\frac{v}{c}$$

and

$$5.953\frac{v}{c} = 3.953$$

Solving for v gives:

$$v = 0.664c = 0.664\left(2.998\times10^8\text{ m/s}\right)$$
$$= 1.99\times10^8\text{ m/s} = \boxed{1.99\times10^5\text{ km/s}}$$

(*b*) From the Hubble equation we have:

$$r = \frac{v}{H}$$

Substitute numerical values and evaluate r:

$$r = \frac{1.99\times10^5\text{ km/s}}{\dfrac{23\text{ km/s}}{10^6\, c\cdot\text{y}}} = \boxed{8.65\times10^9\, c\cdot\text{y}}$$

37 •• [SSM] (*a*) In terms of the quark model, show that the reaction $\pi^0 \to \gamma+\gamma$ does not violate any conservation laws. (*b*) Which conservation law is violated by the reaction $\pi^0 \to \gamma$?

Picture the Problem The π^{o} particle is composed of two quarks, u and $\bar{\text{u}}$. Hence, the reaction $\pi^{\text{o}} \to \gamma+\gamma$ is equivalent to $\text{u}\bar{\text{u}} \to \gamma+\gamma$.

(*a*) The u and $\bar{\text{u}}$ annihilate – resulting in the photons.

(*b*) Two or more photons are required to conserve linear momentum.

38 •• Test the following decays for violation of the conservation of energy, electric charge, baryon number, and lepton number: (*a*) $\Lambda^0 \rightarrow \mathrm{p} + \pi^-$, (*b*) $\Sigma^- \rightarrow \mathrm{n} + \mathrm{p}^-$, and (*c*) $\mu^- \rightarrow \mathrm{e}^- + \overline{\nu}_\mathrm{e} + \nu_\mu$. Assume that linear momentum and angular momentum are conserved. State which conservation laws (if any) are violated in each decay.

Picture the Problem A decay process is allowed if energy, charge, baryon number, and lepton numbers are conserved.

(*a*) Energy conservation:

Because $m_\Lambda > m_\mathrm{p} + m_\pi$, energy conservation is not violated.

Charge conservation:
$0 \rightarrow 1 - 1 = 0$

Because the total charge is 0 before and after the decay, charge conservation is not violated.

Baryon number:
$1 \rightarrow 1 + 0 = 1$

Because there is no change in baryon number, baryon number is conserved.

Lepton number:
$0 \rightarrow 0 + 0 = 0$

Because lepton number is 0 before and after the decay, lepton number is conserved.

The decay is allowed.

(*b*) Energy conservation:

Because $m_\Sigma < m_\mathrm{n} + \mathrm{m}_\mathrm{p}$, energy is not conserved.

Charge conservation:
$-1 \rightarrow 0 - 1 = -1$

Because the total charge does not change, charge is conserved.

Baryon number:
$+1 \rightarrow 1 - 1 = 0$

Because B changes from +1 to 0, baryon number is not conserved.

Lepton number:
$0 \rightarrow 0 + 0 = 0$

Because L is 0 before and after the decay, the lepton number is conserved.

Not allowed. The decay violates both energy conservation and baryon number.

(*c*) Energy conservation:

Energy is conserved.

Charge conservation: $-1 \to -1 + 0 + 0 = -1$

Because the total charge does not change, charge is conserved.

Baryon number: $0 \to 0 + 0 + 0 = 0$

Because B does not change, baryon number is conserved.

Lepton number: $1 \to 1 - 1 + 1 = 1$

Because L does not change, lepton number is conserved.

The decay satisfies all conservation laws and is allowed.

Remarks: The decay in Part (*c*) is the decay process for the muon μ^- (see Example 41-2).

39 •• Consider the following high-energy particle reaction: $p + p \to \Lambda^0 + K^0 + p + (?)$, where (?) represents an unknown particle. During this reaction, stationary protons are bombarded with a beam of high-energy protons. (*a*) Use the laws of conservation of charge number, baryon number, strangeness (**Error! Reference source not found.**), and spin to determine the unknown particle. (*b*) Calculate the Q value for the reaction. (*c*) The threshold kinetic energy K_{th} for this reaction is given by $K_{th} = -\frac{1}{2}Q\left(m_p + m_p + M_1 + M_2 + M_3 + M_4\right)/m_p$, where M_1, M_2, M_3 and M_4 are the masses of the reaction products. Find K_{th}.

Picture the Problem We can systematically determine Q, B, S, and s for the reaction and then use these values to identify the unknown particle. The Q value for the reaction is given by $Q = -(\Delta m)c^2$ and the expression for the threshold energy for the reaction is given in the problem statement.

(*a*) For the strong reaction: $p + p \to \Lambda^o + K^o + p + (?)$

Charge number: $+1 + 1 = 0 + 0 + 1 + Q \Rightarrow Q = +1$

baryon number: $+1 + 1 = +1 + 0 + 1 + B \Rightarrow B = 0$

strangeness: $0 + 0 = -1 + 1 + 0 + S \Rightarrow S = 0$

spin: $+\frac{1}{2} + \frac{1}{2} = +\frac{1}{2} + 0 + \frac{1}{2} + s \Rightarrow s = 0$

These properties indicate that the unknown particle is a pion $\boxed{\pi^+}$.

(*b*) The reaction is: $p + p \to \Lambda^o + K^o + p + \pi^+$

The Q-value for the reaction is:

$$Q = \left[\left(m_{\mathrm{p}} + m_{\mathrm{p}}\right) - \left(M_{\Lambda^0} + M_{\mathrm{K}^0} + M_{\mathrm{p}} + M_{\pi^+}\right)\right]c^2$$

Use Table 41-1 to find the mass-energy values:

$$Q = \left[(938.3 + 938.3) - (1116 + 497.7 + 938.3 + 139.6)\right]\mathrm{MeV} = \boxed{-815\,\mathrm{MeV}}$$

Because $Q < 0$, the reaction is endothermic.

(c) The threshold energy for this reaction is:

$$K_{\mathrm{th}} = -\frac{Q}{2m_{\mathrm{p}}}\left(m_{\mathrm{p}} + m_{\mathrm{p}} + M_{\Lambda^0} + M_{\mathrm{K}^0} + M_{\mathrm{p}} + M_{\pi^+}\right)$$

Using Table 41-1 to find the mass-energy values, substitute numerical values and evaluate K_{th}:

$$K_{\mathrm{th}} = -\frac{-815\,\mathrm{MeV}}{2(938.3\,\mathrm{MeV})}(938.3 + 938.3 + 1116 + 497.7 + 938.3 + 139.6)\mathrm{MeV}$$
$$= 1984\,\mathrm{MeV} = \boxed{1.98\ \mathrm{GeV}}$$

40 ••• In this problem, you will calculate the difference in the time of arrival of two neutrinos of different energy from a supernova that is 170 000 light-years away. Let the energies of the neutrinos be E_1 = 20 MeV and E_2 = 5 MeV, and assume that the mass of a neutrino is 2.0 eV/c^2. Because the total energies of the neutrinos is so much greater than their rest energies, the neutrinos have speeds that are very nearly equal to c and energies that are approximately $E \approx pc$. (a) If t_1 and t_2 are the times that the neutrinos with speeds u_1 and u_2 take to travel a distance x , show that $\Delta t = t_2 - t_1 = x\left(u_1 - u_2\right)/u_1 u_2 \approx \left(x\,\Delta u\right)/c^2$. (b) The speed of a neutrino of mass m and total energy E can be found from $E = mc^2/\left[1 - \left(u^2/c^2\right)\right]^{1/2}$ (Equation 39-24). Show that when $E >> mc^2$, the speed ratio u/c is given approximately by $u/c \approx 1 - \frac{1}{2}\left(mc^2/E\right)^2$. (c) Use the results from Part (a) and Part (b) to calculate $u_1 - u_2$ for the energies and mass given, and calculate Δt from the result from Part (a) for x = 170 000 c·y. (d) Repeat the calculation in Part (c) using 20 eV/c^2 for the neutrino mass.

Picture the Problem The solution strategy is outlined in the problem statement.

(a) Express $\Delta t = t_2 - t_1$ in terms of u_2 and u_1:

$$\Delta t = t_2 - t_1 = \frac{x}{u_2} - \frac{x}{u_1} = \frac{x\left(u_1 - u_2\right)}{u_1 u_2}$$

Noting that $u_1 u_2 \approx c^2$, we have:

$$\Delta t \approx \boxed{\frac{x\Delta u}{c^2}} \qquad (1)$$

where $\Delta u = u_1 - u_2$

(b) From Equation 39-25 we have:

$$\frac{u}{c} = \sqrt{1-\left(\frac{mc^2}{E}\right)^2} = \left(1-\left(\frac{mc^2}{E}\right)^2\right)^{1/2}$$

Expand binomially to obtain:

$$\frac{u}{c} = \boxed{1-\tfrac{1}{2}\left(\frac{mc^2}{E}\right)^2}$$

(c) Express $u_1 - u_2$ in terms of E_1, E_2, and mc^2:

$$u_1 - u_2 = \tfrac{1}{2}c\left(mc^2\right)^2\left(\frac{1}{E_2^2}-\frac{1}{E_1^2}\right) = \frac{c\left(mc^2\right)^2\left(E_1^2-E_2^2\right)}{2E_1^2E_2^2}$$

Substitute numerical values and evaluate Δu:

$$\Delta u = \frac{c\left(2.0\frac{\text{eV}}{c^2}c^2\right)^2\left[(20\,\text{MeV})^2-(5.0\,\text{MeV})^2\right]}{2(20\,\text{MeV})^2(5.0\,\text{MeV})^2} = \boxed{7.5\times10^{-14}\,c}$$

Use equation (1) to evaluate Δt:

$$\Delta t \approx \frac{\left(1.70\times10^5\,c\cdot\text{y}\right)\left(7.5\times10^{-14}\,c\right)}{c^2} = 1.275\times10^{-8}\,\text{y}\times\frac{31.56\,\text{Ms}}{\text{y}} = \boxed{0.40\,\text{s}}$$

(d) Using $mc^2 = 20$ eV for the rest energy of a neutrino:

$$\Delta u = \frac{c\left(20\frac{\text{eV}}{c^2}c^2\right)^2\left[(20\,\text{MeV})^2-(5.0\,\text{MeV})^2\right]}{2(20\,\text{MeV})^2(5.0\,\text{MeV})^2} = \boxed{7.5\times10^{-12}\,c}$$

Use equation (1) to evaluate Δt:

$$\Delta t \approx \frac{\left(1.70\times10^{5}\,c\cdot\text{y}\right)\left(7.5\times10^{-12}\,c\right)}{c^{2}}$$
$$=1.275\times10^{-6}\ \text{y}\times\frac{31.56\,\text{Ms}}{\text{y}}$$
$$=\boxed{40\,\text{s}}$$

Remarks: Note that the spread in the arrival time for neutrinos from a supernova can be used to estimate the mass of a neutrino.

41 ••• A Λ^0 at rest decays by the reaction $\Lambda^0 \rightarrow \text{p} + \pi^-$. (*a*) Calculate the total kinetic energy of the decay products. (*b*) Find the ratio of the kinetic energy of the pion to the kinetic energy of the proton. (*c*) Find the kinetic energies of the proton and the pion for this decay.

Picture the Problem We can use the masses of the parent and daughters to find the total kinetic energy of the decay products under the assumption that the Λ^0 is initially at rest. Application of conservation of energy and the definition of kinetic energy will yield the ratio of the kinetic energy of the pion to the kinetic energy of the proton. Finally, we can use our results in Parts (*a*) and (*b*) to find the kinetic energies of the proton and the pion for this decay.

(*a*) The total kinetic energy of the decay products is given by:

$$K_{\text{tot}}=\left(m_\Lambda-m_\text{p}-m_\pi\right)c^2$$

Substitute numerical values (see Table 41-1) and evaluate K_{tot}:

$$K_{\text{tot}}=\left(1116\frac{\text{MeV}}{c^2}-938.3\frac{\text{MeV}}{c^2}-139.6\frac{\text{MeV}}{c^2}\right)c^2=\boxed{38\,\text{MeV}}$$

(*b*) The ratio of the kinetic energies is given by:

$$\frac{K_\pi}{K_\text{p}}=\frac{\frac{1}{2}m_\pi v_\pi^2}{\frac{1}{2}m_\text{p}v_\text{p}^2}=\frac{m_\pi v_\pi^2}{m_\text{p}v_\text{p}^2}$$

Use conservation of momentum (nonrelativistic) to obtain:

$$m_\pi v_\pi=m_\text{p}v_\text{p}\Rightarrow\frac{v_\pi}{v_\text{p}}=\frac{m_\text{p}}{m_\pi}$$

Substitute for the ratio of the speeds to obtain:

$$\frac{K_\pi}{K_\text{p}}=\frac{m_\pi}{m_\text{p}}\left(\frac{m_\text{p}}{m_\pi}\right)^2=\frac{m_\text{p}}{m_\pi}$$

Substitute numerical values and evaluate the ratio of the kinetic energies:

$$\frac{K_\pi}{K_p} = \frac{938.3\frac{\text{MeV}}{c^2}}{139.6\frac{\text{MeV}}{c^2}} = \boxed{6.72}$$

(*c*) Express the total kinetic energy in terms of K_π and K_p:

$$K_p + K_\pi = K_{tot} \qquad (1)$$

Use our results in (*a*) and (*b*) to obtain:

$$K_p + 6.72K_p = 38\,\text{MeV}$$

Solving for K_p gives:

$$K_p = \boxed{5\,\text{MeV}}$$

Substitute in equation (1) to obtain:

$$K_\pi = K_{tot} - K_p = \boxed{33\,\text{MeV}}$$

42 ••• A Σ^0 particle at rest decays by the reaction $\Sigma^0 \rightarrow \Lambda^0 + \gamma$. (*a*) What is the total energy (total energy includes rest energy) of the decay products? (*b*) Assuming that the kinetic energy of the Λ^0 is negligible compared with the energy of the photon, calculate the approximate momentum of the photon. (*c*) Use your result from Part (*b*) to calculate the kinetic energy of the Λ^0. (*d*) Use your result from Part (*c*) to obtain a better estimate of the momentum and the energy of the photon.

Picture the Problem The total energy of the decay products is the rest energy of the Σ^0 particle. We can find the momentum of the photon from its energy and use the conservation of momentum to calculate the kinetic energy of the Λ^0.

(*a*) The total energy of the decay products is given by:

$$E = (m_\Sigma)c^2$$

Substitute numerical values (see Table 41-1) and evaluate K_{tot}:

$$E = \left(1193\frac{\text{MeV}}{c^2}\right)c^2 = \boxed{1193\,\text{MeV}}$$

(*b*) The momentum of the photon is given by:

$$p_\gamma = \frac{E_\gamma}{c} = \frac{E - m_\Lambda c^2}{c}$$

Substitute numerical values and evaluate p_γ:

$$p_\gamma = \frac{1193\,\text{MeV} - \left(1116\frac{\text{MeV}}{c^2}\right)c^2}{c} = \boxed{77\frac{\text{MeV}}{c}}$$

(c) The kinetic energy of the Λ^0 is given by:

$$K_\Lambda = \frac{p_\Lambda^2}{2m_\Lambda}$$

or, because $p_\Lambda = p_\gamma$,

$$K_\Lambda = \frac{p_\gamma^2}{2m_\Lambda}$$

Substitute numerical values and evaluate K_Λ:

$$K_\Lambda = \frac{\left(77\,\frac{\text{MeV}}{c}\right)^2}{2\left(1116\,\frac{\text{MeV}}{c^2}\right)} = \boxed{2.7\,\text{MeV}}$$

(d) A better estimate of the energy of the photon is:

$$E_\gamma = E - m_\Lambda c^2 - K_\Lambda$$

Substitute numerical values and evaluate E_γ:

$$E_\gamma = 1193\,\text{MeV} - \left(1116\,\frac{\text{MeV}}{c^2}\right)c^2 - 2.7\,\text{MeV} = \boxed{74\,\text{MeV}}$$

The improved estimate of the momentum of the photon is:

$$p_\gamma = \frac{E_\lambda}{c} = \boxed{74\,\frac{\text{MeV}}{c}}$$
